Propagation of Phlox subulata and Aubrietias.

The propagation of Phlox subulata and its varieties presents some difficulties to many cultivators, owing to the hardness of cuttings taken from outside plants. These choice alpines will soon be flowering, after which they should be cut back and a few plants lifted carefully, potted up, and placed in gentle warmth. Plenty of growths suitable for cuttings are produced. Take them off when quite small—an inch long is sufficient, and dibble them in round the edges of small pots filled firm with a mixture of loam, leaf-soil and sand in equal parts. Place the pots in a box covered with a sheet of glass, where they will root quickly, when they should be placed in a cold frame. The same method applies to the aubrietias.—J. N.

Staking Sweet Peas.

The following method of staking clumps of sweet peas is worthy of a trial: When sowing or planting the seedlings, place them around the outside of an 18in. or 2ft. circle. Then place the sticks in the *inside*—always using a few small twigs outside, to give the seedlings a start in their climbing. If wire netting is used, adopt the same method of putting the netting and supports *inside* with the peas outside. Throughout the season the plants will be covering the supports, enhancing their appearance, and the flowers do not get damaged by being blown across the twigs. An occasional tie right round with raffia or fine string helps to keep them together. Half the usual number of sticks will be sufficient.—F. L. B.

Burning Rubbish.

Procure 1yd. or 2yds. of coarse wire netting and two or three metal stakes. Shape the wire netting into a wide-mouthed cone. Drive the stakes firmly into the ground, and fasten the cone of wire between them with its mouth upwards and its bottom point a few inches above the ground. Waste paper, dead flowers, leaves and all light rubbish will burn away quite clean without any attention, and the ashes will fall through the wire to the ground.—C. J.

A Handy Weeding Tool.

A tool that will save much backache during the coming summer can be made in a few minutes by the least experienced handyman, for it is simply a small hand-fork fitted into a shortened broom handle, 3½—4ft. long being most convenient for persons of average height. With an implement of this length, flower beds can be lightly forked over with the utmost ease and rapidity, while it will be found that one may work the soil right up to the base of the plants. This tool is particularly useful for weeding beds containing bulbs, for with the ordinary hoe there is always the danger of cutting off a few plants if the work is done over-rapidly—a danger that is non-existent when working with a small fork.—B. D.

GROW MORE PANSIES AND BRIGHTEN YOUR GARDEN.

PANSIES have long been favourites in our gardens, both for their beauty and ease of culture, and their popularity is now on the increase The more modern varieties and strains show a distinct advance in size of flower and range of colour over the older types, and for that reason they should form part of every garden display. The best time for sowing seed is from now on until the end of May, which will give flowering plants next year, while plants may be obtained and planted now for blooming and adding colour to the garden this summer.

VOL. XCI.—No. 2890. APRIL 23, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

Pansies and Violas from Seed.

I AM glad to know that the love of pansies is again on the upgrade. Specialists amateur or trade, grow named varieties which are propagated by cuttings and consequently every plant is true to colour and type. This is not so with seedlings, though many strains of yellow, blue, white and purple come remarkably pure from seed and in a mass look the same, but, trueness from the real fancier's point of view, *means* trueness—that is, without any variation in colour, form, outline of blotches or eye. In the named exhibition varieties of pansies and violas, this counsel of perfection is attainable. To those who do not wish to graduate into this school, let me advise the growing of pansies and violas carefully from seed. The very best time for sowing is from now to the end of May. The best seedsmen dare not nowadays handle anything but seed which will give good results and, consequently, there are many good strains about. The method of procedure is the same with all classes. Sow the seeds *thinly* in a box, cover lightly (not more than a quarter-inch of fine soil). It is well to water the soil in the box thoroughly the day before sowing and if not stood in direct sun it should want very little more till germination takes place. It is a good plan to place a sheet of glass over the box and a piece of brown paper over the glass till the young plants peep through the soil. The box can be placed either in a frame or cool greenhouse. The next process, when the young plants are about an inch tall, with two or three leaves the size of one's thumb nail, is to transplant them into a prepared bed in the open, or into the soil of a cold frame. This soil should be made kindly by the addition of a little very old well rotted manure or some leaf-mould and a little sand, if convenient. The idea is to get plants in August and September bushy and healthy with a mass of fresh young roots which must be lifted with a hand fork to get the roots as complete as possible. In the frame the plants should be about 3ins. apart. Plant out in beds or borders where they are to flower in August or September and 95 per cent. of them will come through the winter unhurt and grow during most of it. By April, buds will be showing and the plants will start flowering in May and continue for several months, especially if old flowers are picked and prevented going to seed. Seedling plants from good strains of pansies and violas are a great source of interest in the first stages of blooming, because new beauties are revealed daily. If any plants yield flowers of special quality and attractiveness, nothing is easier than perpetuating them. Pull out a few of the young centre growths and plant them in a shady corner in a frame or even in the open ground and they will soon make plants, especially if young rootlets are attached to the pulled-out cuttings.—WM. CUTHBERTSON.

This Week's Work

For Gardens in the South and Midlands.

Sow seeds of biennials, such as sweet williams, canterbury bells, wallflowers, polyanthus, etc.

Disbud apricots, peaches and nectarines.

Plant out from nursery beds cabbages and cauliflowers.

Sow peas and dwarf beans.

Pot up gloxinias, tuberous-rooted begonias and young perpetual carnations.

Harden off tender seedlings by placing them in cold frames.

Plant out onions raised in boxes.

Plant evergreen shrubs.

Continue to sow hardy annuals.

Finish pruning tea roses and planting gladioli

Photographic Competition Rules.

1. All photographs sent in must be taken by the reader or submitted with the consent of the actual photographer.
2. Prints should be on smooth surface paper and preferably in black tones, and can be of any size. Figures may be included where these are helpful to the composition.
3. Prints need not be mounted and negatives must not be sent.
4. The name and address of the sender must be clearly written on the back of each photograph, together with a few explanatory words, such as the names of the flowers, where grown, when planted or sown, or anything which gives point or lends interest to the picture.
5. Each photograph must be accompanied by a coupon, to be found on page xvii, and a piece of cardboard should be used to prevent damage in the post. Envelopes should be marked "Photographic Competition" on the outside and addressed to The Editor, THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2.
6. A stamped addressed envelope must accompany all photographs. The Editor will endeavour to return those which are considered unsuitable. If this rule is not complied with, prints will not be returned.
7. The Editor will not hold himself responsible for photographs lost or damaged in the post or otherwise.
8. No correspondence can be entered into.
9. All photographs published will become the copyright of THE GARDEN.

To the reader who sends in the photograph which the Editor considers the best of the week a prize of 21s. will be awarded. For all other competition photographs published 5s. will be paid. Payment will be made about the 7th of the month following publication.

We are indebted to Messrs. Dobbie and Co. of Edinburgh for the coloured illustration of pansies which appears on our front cover this week.

This Week's Work

For Gardens in Scotland and the North.

Finish planting second early potatoes.

Harden off onions and leeks raised under glass.

Plant onion sets if not already done.

Pyrethrums succeed when planted now.

Plant edgings of catmint raised from cuttings.

Repot aspidistra and other house plants.

Spray fruit trees with nicotine wash.

Plant aquilegia in mixed flower border.

Remove half hardy annuals to a cold frame.

Continue to plant out cabbages.

Start begonias into growth.

Sow Brussels sprouts for late winter use.

A DESIGN FOR THE SMALL GARDEN

THE owner of the small garden, and more especially of the *very* small garden, has many difficulties to contend with in its lay-out. What are known as "natural" schemes are not for him, and the simple, straightforward lay-out of straight paths of turf or gravel between rectangular borders, while, if properly carried out, not ineffective, cannot be considered to display much originality. Of all the styles of gardening which have had any vogue in this country, the Dutch is the one best suited to small areas. The Dutch garden, however, in its original form is rather suited for a small enclosure in a large garden, than as the main or even sole feature of a small one. Box or lavender hedges and masses of formal colour do not afford sufficient variety of planting to satisfy the average garden lover. But we may preserve the best and most characteristic features of the Dutch garden without retaining its extreme formality and rigidity. And where, in a Dutch garden, properly so called, there would be formal edgings of box or tile, we may boldly employ informal groupings of plants in the modern manner. That a formal garden planted almost or quite informally, can be truly delightful, the "Flower-garden" at Gravetye Manor—to give but one example—bears perpetual witness.

Little stairways should be much in evidence, though in the very small garden these will each consist of only one or two very shallow steps. And the pavement should be diverse in colouring, pattern and material. Unless beneath a pergola, paths in a large garden are best as simple as possible. Where space is very limited, however, quaint patternings are not merely allowable, but desirable. It is surprising what diversity may be attained by the use of flag-paving, bricks (old or new) and cobble stones. "Noelite" hand-made paving tiles are most attractive for paving and forming border edgings. They are easily laid, quite inexpensive, and particularly suitable for small formal gardens.

Cobble stones may often be picked up on the site, but bricks and paving stone have commonly to be bought. Many bricks which would be perfectly suitable for house building perish lamentably when used for paving, which is subjected to extremes of heat and cold—especially cold—when water logged. Proper paving bricks, then, should always be selected. A very little paving stone may be made to go quite a long way in this style of path-making, but it is desirable to get variety of colour in the material, so that a "job lot" of crazy and broken paving from the local builder may be the very thing for the purpose. All the materials should be laid over a well drained foundation on a bed of finely sifted dry boiler ashes, and should be closely jointed in good cement. Two parts of really clean sharp sand to one of cement is the best proportion. Mix the ingredients thoroughly while still dry, use water sparingly and "elbow-grease" freely. First of all lay any bricks or flagstones, jointing them as the work proceeds; and then tap down the cobble stones into a bed of mixed cement about ½in. thick. When the cement is beginning to stiffen, but before it becomes hard, rake back the joints for a quarter of inch or so with the point of the trowel or a bent, rather slender iron rod.

The little plan of a lay-out in this style for a tiny garden (Fig. 1) speaks almost for itself. The Dutch style lends itself especially well to filling awkward corners and spaces. Regular pentagons, heptagons and other figures scarcely admissible with other severer styles may be used without fear, if they will help to reconcile divergent lines of approach.

An almost infinite number of pleasing designs can be worked out for the pavement, but perhaps the three simple ones which accompany this article (Fig. 2) may be helpful as affording ideas. In all of them cobble stones are used pretty freely and paving stone in small quantity. All the paths here suggested are 3ft. wide. The path shown at A is paved mainly with bricks, but a small quantity of stone is introduced to form various patterns down the centre. Where cobble stones are hard to procure—and they are, I find, in some localities—the straight margins may be laid with gravel or with the red burnt ash which is utilised for hard tennis court. Path B uses cobble stones freely, bricks in reason and an inconsiderable amount of small pieces of paving; the large diamonds being outlined with old tiles laid on edge; but paving on edge or white cobble stones could be used instead of the tiles. At C cobble stones are again largely in evidence, but use is found for larger pieces of paving and the bricks are laid on edge. Where a central stone is used to form the boss of an ornamental feature as in the diamond in B (Fig. 2), it may well be of different colour or tone from the "petals." In some localities a great variety of colouring is obtainable in cobble stones, and a certain amount of pattern may be introduced into the cobbled areas, but the use of variously coloured bricks is, as a rule, to be deprecated. A deep, rich red is the best colour for paving, as for building bricks. The treatment of the little squares, rectangles, octagons, hexagons, circles and other regular or symmetrical figures so characteristic of this class of work is really easier to work out than that of straight paths, for the shape of the space to be treated will, in general, suggest a pattern. The writer has designed many Dutch and "near-Dutch" gardens, but has never yet had to fall back upon the same *motif* for the paths. From the point of view of the small garden-owner, however, one great advantage of this style of path making is that it can be formed from a variety of cheap materials—odds and ends—and that he can employ *his own ingenuity* to form designs with just the materials at hand. Other advantages are the permanent maintenance-free character of the work and its entire freedom from weeds.

As regards the planting of the beds and borders, this will largely depend upon the characteristics and capabilities of the soil, environment (or atmosphere) and climate—to say nothing of individual preferences. The following points should, however, be borne in mind. It is desirable to emphasise

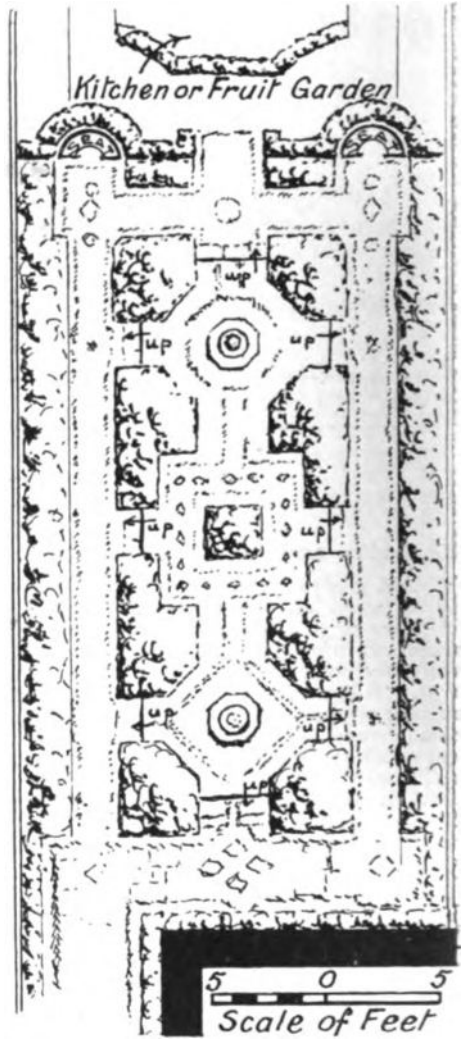

FIG. 1.

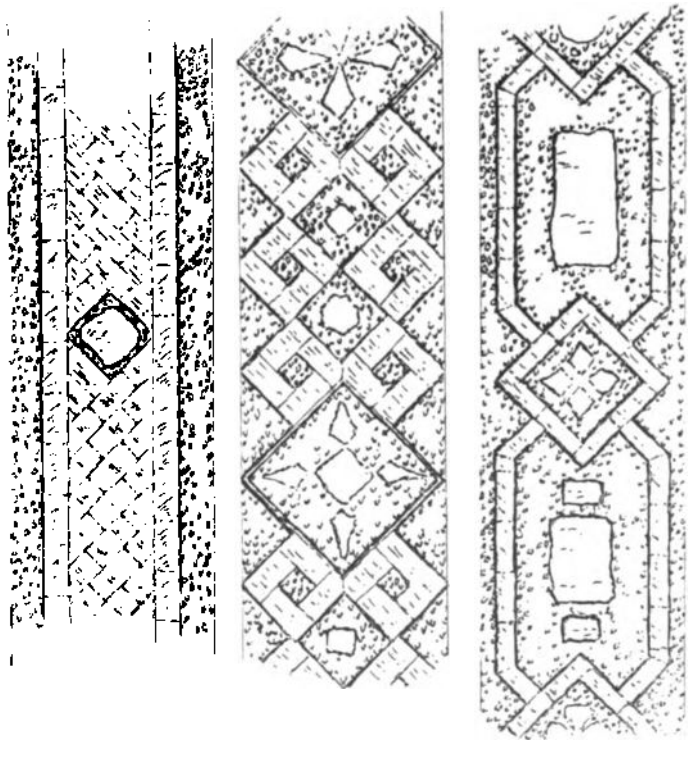

FIG. 2.

A B C

Digitized by Google

THE FORMAL STYLE OF GARDEN IS ONE WHICH CAN BE CARRIED OUT EVEN IN LIMITED SPACE PROVIDED THE PROPORTIONS ARE ALTERED ACCORDINGLY.

important features—central points, steps, stairways, etc.—by the use of shrubs of formal or fastigiate (columnar) outline. The grey-foliaged Irish juniper is very useful for this purpose, but there are many other good plants available. Again the grey or brown of most stone pavings provides an ideal foil for plants with silvery foliage and for those with crimson, purple or creamy flowers. That large, tall growing plants are unsuitable for small beds goes almost without saying, and the dwarf plants should not be overcrowded.—R. G. W.

THE USE OF SCARLET FLOWERS

THE very interesting article in THE GARDEN for January 29th on "Scarlet and Grey in the Garden" calls attention to the possibilities—and impossibilities—of this most brilliant of flower colours. The writer has heard it seriously argued that scarlet is a flower colour alien to our climate and, consequently, one that should be eschewed.

Your correspondent confines himself to grey as a foil colour, using "grey" to cover such tones as the cloudy blues—or purples—of Clematis Lady Londesborough and Echinops niveus and also the silver greys of Cerastium tomentosum and several artemisias. On similar lines one might well use the paler forms of Campanula lactiflora and the dilute purple forms of many other campanulas, including such as CC. latifolia, sarmatica, barbata and carpatica. These things are, in fact, well enough with the green foliage of Lychnis chalcedonicum, Oriental or Shirley poppies, scarlet gladioli and Paul Crampel pelargonium, but less happy—at least in the writer's judgment—with the bronze or even reddish purple foliage of many other scarlet flowers. A tone of colour which conforms remarkably well with scarlet flowers *and* bronzy foliage is ivory white, never seen to better advantage than in that stately bulbous plant Galtonia candicans. Other border flowers which come to mind with more or less the same colour tone are Spiræa Aruncus and its variety Kneiffii, Filipendula (Spiræa) Ulmaria, Thalictrum aquilegifolium var. album, Clematis recta, Iris sibirica alba, both species of bocconia and certain dahlias. It will be noted that quite a number of the kinds

THE RICHLY COLOURED ORIENTAL POPPIES.

mentioned ask for a cool and, if possible, rather stiff soil. They thus mark themselves out as specially suitable for association with Lobelia fulgens, the more brilliant herbaceous phloxes and Mimulus cardinalis.

Another way of utilising scarlet flowers is to form a bed of the kind favoured against a background of suitable vegetation. The writer has never seen Paul Crampel pelargonium to such advantage elsewhere as when it is grouped fairly boldly in front of a solid dark background, preferably of yew. Lobelia fulgens looks specially fine as a foreground to Arundo Donax or, where suitable conditions exist, against the glaucous foliage of Cedrus atlantica glauca, Abies concolor or Picea pungens glauca.

It is by no means necessary, however, to isolate scarlet flowers from all other strong colouring. But here we "come up against" the question of what *is* scarlet. There is obviously a great gulf fixed between, say, Lobelia fulgens Queen Victoria—this is still the best coloured of the so-called scarlet lobelias—and Geum Mrs. Bradshaw. The lobelia may be grouped most effectively with the crimson maroon and red-purple forms of the species, and even the rose forms will not suffice to create a discord. But no such liberty may be attempted with the geum. Yet this latter may be associated with orange, apricot and golden flowers—especially geums—and remain innocuous.

I have already written at more length than I should, so will conclude with a few more words about scarlet flowers. It is,

Digitized by Google

A WELL PLANTED BED OF SCARLET GLADIOLI AND GOLDEN VIOLAS.

F think, to be regretted that the field poppy (Papaver Rhœas) is not more used nowadays as a *scarlet* flower. The beautiful delicate tones and tints now available in the Shirley poppy should by no means detract from the value of the original scarlet, which is equally valuable with the black centre of the wild species or the bold white "cross" of the scarlet Shirley. Perhaps the latter is more a "garden" flower and—in case our neighbours save their own "Shirley" seed—is less likely to spoil their strain by cross-pollination.

I will conclude by mentioning a few first-rate plants with scarlet flowers not mentioned by your correspondent. There is quite a number of other scarlet gladioli besides the species brenchleyensis, and some belong—more or less—to the primulinus set. Other scarlet lilies include Lilium pomponium and the plant which often does duty for it, L. pyrenaicum rubrum. Several phloxes of the decussata set are as scarlet as Geum Mrs. Bradshaw, notably Coquelicot and George A. Ströhlein. Two plants with rather similar requirements are Ranunculus asiaticus and Habranthus pratensis—and both palpitate with colour. The ranunculus is a parent of the Turban, French and Persian cultivated forms, and some of these are equally bright in colouring. Anemone fulgens is another "brilliant" though not summer flowering.

Among bedding annuals and tender perennials commonly grown outdoors which usually have scarlet flowers or of which forms with flowers of scarlet colouring are obtainable may be mentioned Salvia coccinea, certain dahlias and eschscholtzias and the zinnia. Snapdragons of almost scarlet tone are listed, and the same may be said of the sun rose, Helianthemum vulgare. G. W.

DAHLIAS FOR THE BORDER

In the following article the decorative and cactus-flowered types are described. Many of the varieties are admirable for growing in the town and suburban garden for a bright display in late summer and early autumn.

THE dahlia is an ideal flower for the town or suburban garden, unless the plot is entirely shaded by trees. These are the greatest evil the town gardener has to contend with, even if not in his own domain, his neighbour may be doubly blest in this direction. If a few branches are judiciously cut off, all will be well for the dahlias, if the soil is dug 2ft. deep and the roots of the trees curtailed. Under such conditions it will be necessary to see that the plants do not suffer from drought during the summer months, or many of the flowers will not develop. A mulching of hop manure or grass from the lawn mower will be an advantage. Beds or borders filled with dahlias are very effective, and when in massed formation the plants should be placed more closely together than is generally the rule. The grower of a few plants only will probably plant them in the herbaceous border, and here it is advisable to have two or three examples of one kind, arranging each sort in a clump, when a distance of 3ft. to 4ft. should be allowed between the roots.

DECORATIVE VARIETIES.

The decorative type of dahlia is extensively employed for beds in public parks, and gardens; while they are useful for filling large vases for house decoration. It is a section that can be strongly recommended to the amateur and small grower, and in larger establishments they have been held in high esteem for several years, which is a further proof of their popularity. Moreover, they are at their best when the glory of the ordinary border is on the wane. There is quite a large number to choose from, but the following varieties came under my eye last summer, and are suggested purely for their garden value:

Artis.—Orange scarlet, 3ft.

Crimson Flag.—Fiery crimson, very free, excellent for massing; 3½ft. A fine dahlia.

Brentwood Yellow.—A good bedding variety, free, 2½ft.

Souvenir de G. Douzon.—Orange red, 4½ft.

Border Perfection.—Deep scarlet crimson, large flowers, 3ft.

Dauntless.—Orange scarlet, 4ft.

Enchantress.—Rose pink, with twisted petals, 4ft.

Fireflaire.—May be termed a decorative hybrid cactus, vermilion scarlet, 4–5ft.

Insulinde.—Golden orange, extra good, 3–5ft.

Jubilee.—Silvery lilac mauve, 4ft.

Miss Mallison.—Deep clear mauve, 4ft.

Psyche.—Deep chrome yellow, 4ft.

Rev. John Robinson.—Deep lilac, 4ft.

Warneford.—Fine white, excellent, 4ft.

Dream.—Soft salmon, 3–4ft.

The decorative forms are characterised by their fine bold and handsome flowers, the stiff stems displaying the blossoms well above the foliage.

THE CACTUS-FLOWERED VARIETIES.

The cactus forms are quite as numerous as the decorative, and this type has been considerably improved of late years, and we possess fewer varieties now that have a habit of losing their flowers in a mass of foliage. The following will be found satisfactory:

America.—Cactus fancy pink striped carmine, 4ft.

Alabaster.—Pure white, fine, 3–4ft.

Beauty of Penshurst.—Pale pearly pink, good, 3–4ft.

Edgar Jackson, salmon, a fine variety, and one of the best for the garden, 4ft.

F. W. Fellowes.—Orange scarlet, 5ft.

John Riding.—Deep crimson, good, 3ft.

A FINE BED OF WHITE DECORATIVE DAHLIAS.

Digitized by Google

Harvester.—Yellow to orange, free, 2½ft.
Nellie Riding.—Crimson, tipped white, 4ft.
Pierrot.—Deep amber, tipped white, 4ft.
Sydney Jones.—Pink, yellow tipped, 4ft.
Ivory White.—Good habit, 3ft.
Viceroy.—Orange scarlet, 4ft.
Canary.—Sulphur yellow, fine. 3-4ft.

All the varieties quoted possess a good constitution, and the heights given are approximate, so much depending on the season and the condition of the root run.

SOIL.

Dahlias as a class are easily grown, they will succeed in any ordinary garden soil, and where it has not been disturbed for several years it is a good plan to dig at least two spits deep. Good partly decayed farmyard manure is often recommended, but this is difficult to procure, and even so I have found bone-meal produce better results. Sprinkle it over the soil so that the latter appears white, and then fork in. With bone-meal the growth is not quite so rank, the foliage is less dense, and the flowers are of finer quality, few being distorted in any way.

PLANTING.

Dormant roots may be planted at the end of April, and cuttings, or those started in a shed or frame about the middle of May. If there is any fear of frost an inverted flower-pot set over each plant will prevent injury. Dahlias usually commence to bloom in July, and continue until cut down by frosts, when they are lifted and stored in a frost-proof shed for the winter. When plenty of cut bloom is required, a few rows across the kitchen or reserve garden will be useful, when a distance of 5ft. is allowed between the lines, and 3ft. to 4ft. from root to root. If old clumps are planted it will be advisable a little later on to remove all weak growths, leaving three or four of the best to develop.

EVERGREEN HEDGES

In the following article are described a number of useful evergreens which will make admirable hedge plants in the small garden. They can all be planted now in showery weather.

THE garden year begins properly in the autumn, and those who have been both industrious and fortunate will already have had satisfactory rendezvous with most of the hardy perennials and shrubs. Many people, however, having gathered their last posy and swept up the leaves at the end of the year, feel no further call to activity until spring overwhelms them with immediate duties in all quarters of the garden.

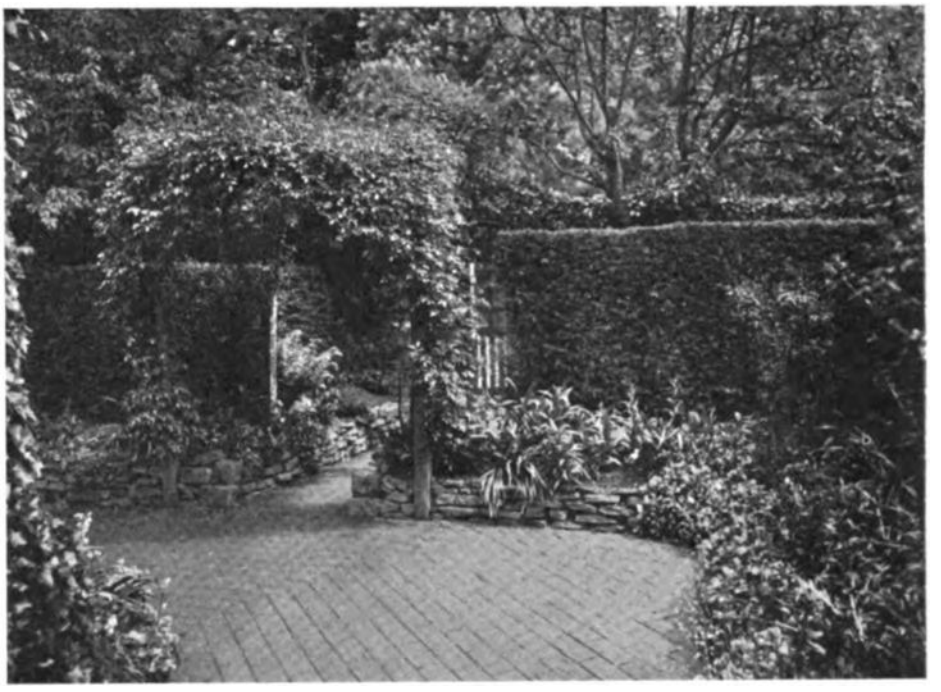
While it is unwise in most cases to attempt the moving of deciduous trees and shrubs after March, most evergreens can safely be planted up to the middle of May. In certain districts and on very hot, dry soils it is better to plant in September or October, but under average conditions April is an excellent time. The bitter drying winds of March are safely past, plenty of moisture is available, the ground is already warmer, but as yet the sun is not too strong for only partly established roots. It must be remembered that evergreens have little or no dormant season and so need every care and favourable condition, so that they do not suffer from the shock of transplanting.

There is so much choice of living material for every garden purpose that not even the most practical problem need be treated purely from its utilitarian aspect. Boundaries should appeal to the eye as well as to sense; shelter belts planted against unfavourable aspects may have a grandeur as impressive as their efficiency, and screens to hide ugliness or defeat curiosity may well substitute something which can legitimately be admired.

The answer to many garden problems, such as the provision of shade or shelter and privacy, can be found in a selection of good evergreens. No one will quickly forget a grove of yews grown to their natural height and form, or an immense screen of dark holly almost unrestricted. On a smaller scale are such friendly things as the Pyracantha thorn, rather over-planted, but redeeming many a suburban villa from dreary hideousness; and the laurustinus, healthy, crisp and clean in growth, and beautiful in its flowering season. The aromatic rosemary, almost as early with its blossoms of pale Copenhagen blue, might be used more frequently instead of the heavier box, slightly trimmed to emphasise definite points in a design. Then there is the tree lupin, with none of the sombreness sometimes complained of in evergreens, but all the charm of leaf and blossom of the herbaceous species. Its sprays of delicate foliage are a joy both in the garden and for winter vases. More uncommon is Ceanothus thyrsiflorus, a blue cloud in summer and doing in the open as well as on a wall except in the north. Choisya ternata, the fragrant and exotic-looking Mexican orange, also proves unexpectedly hardy.

Few things give such distinction and character to a garden as a well grown hedge, whether it be a high solid rampart, close-clipped and impenetrable, or a more informal affair, marking a subdivision of the garden and serving gently to titillate curiosity rather than to repel intrusion. Where walls are beyond the means of most garden makers to-day the hedge has this in its favour, that it will act as a windbreak without excluding air from the garden and cannot, as sometimes happens with a wall, convert a current of air into a draught, unpleasant to man and devastating to plants. The best of all hedge plants is undoubtedly the yew, for almost any soil or position, though it will not endure standing water at the roots. It is reasonably quick in growth if the plants are put in when quite small. Holly comes next, doing better near the evil influence of a town atmosphere. It is even more intolerant of a water-logged soil, not so long-lived, and takes up more room, as it will not stand such close clipping as the yew. Spring planting sometimes fails in a dry season unless plenty of water can be supplied until the roots are established.

Little need be said of the privet. Its rapid and easy growth is well known and this forms its chief recommendations. It is an entirely inadequate boundary and extraordinarily greedy. Coniferous hedges such as Thuja plicata and Cupressus macrocarpa are apt to become patchy after some years and are not so long lived as either yew or holly, but are, nevertheless, to be recommended. Gorse makes an excellent rough hedge on poor soils. It can be most useful in an exposed position to prevent the drift of snow across a drive.



A SMALL PAVED FRONT GARDEN.

Showing the value of a yew hedge as a screen and a background for lighter foliage and flowers.

Of smaller hedge plants, Lonicera nitida, an evergreen honeysuckle recently introduced, seems to fulfil the many promises made for it, in that it is quick-growing, neat and efficient, doing well in most places, including near the sea. Berberis stenophylla makes a delightful hedge for a garden enclosure. It is graceful in habit, with long arching sprays of yellow blossom in spring.

Chiefly in larger gardens, evergreens such as yew and laurel may be used for arbours. In small places where a hedge is still permissible and effective, so dark and solid a mass would be oppressive or even ridiculous. The yew parlour, a turf enclosure with hedges not too high, and possibly a small deciduous tree for overhead shade, is another feature needing judgment in use. It makes a very pleasant and shady retreat where the size and style of the garden permit.

THE BUSY MAN'S PAGE

Beet, Carrots, Onions—Present Sowings.

Carrots. — Carrots for early use may be sown very early in spring in moderately dry, sheltered borders or frames, forming successions every three or four weeks, and sowing the main crop about the middle or end of April. For carrots the soil should be dug deeply, mixing the soil with soot and lime. Give no rank manure. Apply 2½–3oz. superphosphate, 1½–2 oz. potash salt, and ½oz. sulphate of ammonia per square yard. Sow in drills 9–10ins. apart, using 1 oz. seed to 100–120ft. run. Tread the plot moderately firm, rake smooth and level. If a little fine sand can be scattered over the rows and lightly raked, it will help to prevent the surface from caking.

Onions. — Sow in rows 9–10ins. apart on thoroughly well prepared soil. An admixture of clay improves an onion bed, as it helps to firm the soil. You can hardly make the bed too firm, or the surface soil too fine. Do not sow too deeply. Half an inch of fine soil is more than enough to cover the seeds. Give 3–3½ oz. superphosphate, ½oz. muriate of potash and 1 oz. sulphate of ammonia per square yard.

Beetroot.—Like most other crops, beetroot must be sown on deeply dug soil, and, in order to avoid forked roots, give no rank manure, but see that the artificial fertilisers are well forked into the soil and very evenly distributed. Apply 3 oz. superphosphate, 2½ oz. kainit and 1 oz. sulphate of ammonia per square yard.—J. W.

Phlox from Cuttings.

THE method most commonly adopted to increase phlox of the ordinary type is to divide up the roots, but as cuttings can be struck easily at the present time, this affords an additional opportunity to increase one's stock of a particularly desirable variety or to work up a fresh batch of young plants altogether, and this is very necessary if phlox are grown to any extent. Shown in the illustration on this page is a clump of phlox raised last year from a cutting and which has, in addition to a vigorous centre shoot, several strong young growths arising from the base, and it is from growths such as these that the best cuttings are obtained. Shoots similar to these should, therefore, be removed when about 3ins. or 4ins. long, trimmed with a clean cut just below a joint and inserted in pots of sandy soil in the manner shown in the same illustration, or, if preferred, several cuttings may be inserted in one pot, in which case they will require to be either planted out or repotted immediately they have made sufficient roots.

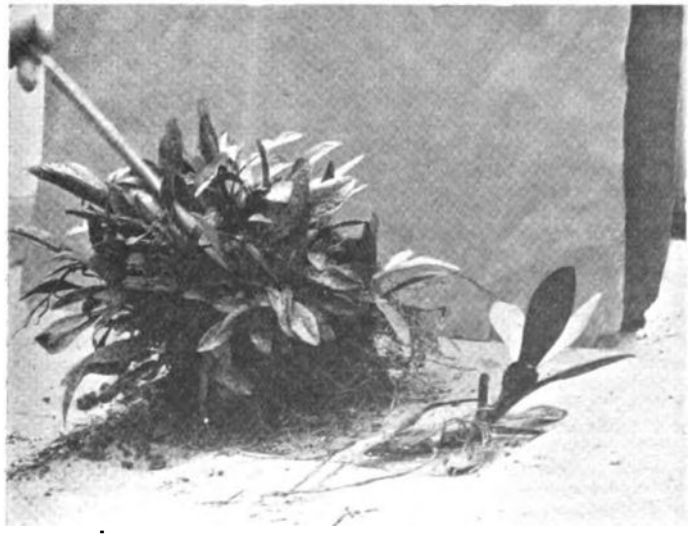
The pots containing the cuttings should then be well watered, placed in a cold frame and kept close for a week or so, when they will soon root, after which they can be hardened off and planted out in their flowering quarters.

CUTTINGS OF PHLOX MAY BE TAKEN AT THE PRESENT TIME.
Strong side shoots, 3ins. to 4ins. long, should be taken off and inserted in pots of sandy soil.

Replanting Michaelmas Daisies.

THERE is still time for the breaking up and replanting of Michaelmas daisies, although no time should be lost in doing this so that the plants may be established before the dry weather sets in. A typical clump of Michaelmas daisy ready for breaking up and replanting is shown in the accompanying illustration, and if this is examined it will be seen that all the vigorous young growths are to be found towards the outer edge of the clump, while the centre, indicated by pointer, will be seen to consist of the worn-out and now useless growths of the previous year. The customary procedure is to break up such a clump into a number of smaller clumps and replant these, the centre being discarded and thrown away.

If, however, strong single growths similar to the example shown to the right of the clump illustrated are detached and planted out, these will have ample room for the development of side branches and will produce well shaped sturdy plants covered with flowers much superior in size and quality to those produced by plants grown in large clumps. The staking of such plants is also an easy matter, as one good strong stake will be found to be adequate and at the same time inconspicuous.



BREAKING UP MICHAELMAS DAISIES.
All the vigorous young growths on the outside of the clump should be selected for replanting.

How to Apply Lawn Sand.

LAWN sand serves the double purpose of assisting the growth of the grasses and at the same time helping to keep down weeds. The active principle of lawn sand is either sulphate of ammonia or sulphate of iron. Some of the advertised sands contain the former to the extent of 30 per cent., and these are excellent for assisting the growth of grass so that weeds are choked and prevented from disfiguring the lawn. The sulphate of iron mixtures are more for killing weeds and giving the grass a rich colour than for use as a manure. These lawn sands can be bought in prepared form, but it is most important that they should be used with care and according to directions. There is no doubt that lawn sand kills the foliage of the broad-leaved weeds, but it is also true that, unless the application is made properly, the grasses may be burnt up as well. Lawn sand should be applied by means of a dredging box, or, failing this, a tin with a few small holes punched in the lid will serve. The sand should only be applied during dry weather. The amount of lawn sand scattered should be from 2 oz. to 4 oz. a square yard, but, as has been stated, it is most important to follow the supplied directions. It should be remembered that, in the case of weeds with strong root stocks, lawn sand will only burn the foliage, and in such cases the only satisfactory way is the removal or destruction of individual roots.

Swan River Daisies for Present Sowing.

ANY suitable subjects for the rock garden that will flower during the summer are especially welcome. In this connection it is worth while planting vacant places with Swan River daisies (brachycome). These are brilliant annuals which flower with great freedom throughout the summer and up to the coming of frost. The flowers resemble small cinerarias, and in the different varieties are blue, purple, rose and white. The Swan River daisy, which grows to the height of about 9ins., is particularly suitable for massing, and it will then produce those patches of bright colour which are so desirable in the rock garden. Swan River daisies may be sown in the protection of a cold frame in April and, when the seedlings are of a size to handle, transplanted to 3ins. apart. They will be ready for placing out of doors during May, and will succeed best when given full exposure to the sun. Plants raised in this way come early into flower, but almost as good results are secured by sowing in the open in April. Thin out so that the plants are not too much crowded in their young stages.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Unusual Vegetables.

THERE are several very useful vegetables which are not grown in the average garden. Take for instance, the Dutch brown bean, a variety of French bean, and grown in just the same way. This is a very heavy cropper and if only on account of the nutritive value of the beans, it should find a place in every allotment or small garden. The beans are allowed to form and ripen in the pods, shelled like peas and cooked just as haricots. Their flavour is delicious and as the beans can be stored and used throughout the winter, they are doubly useful.

Kohl Rabi.—This is a turnip stemmed cabbage. The stem is thick and swollen like a turnip growing above the ground, and is crowned with leaves. When boiled it is sweeter, more nutritious and more solid than either cabbage or white turnip. Sow the seeds in rows 2ft. apart, allowing 1ft. between the plants in the rows.

Vegetable Oyster.—Salsafy, on account of its flavour, is sometimes called "Vegetable Oyster." The root is the part eaten and the soil for the crop must therefore be deeply worked. Where possible place a layer of manure underneath. Sow the seed in drills, an inch deep and 15ins. apart, with 9ins. between the plants. Hoe frequently, but take care not to injure the roots. The plants are left in the soil all winter, and in the spring the young plants a few inches high may be cut and cooked as a substitute for asparagus.

Round Spinach is easy to grow, but a little care must be given to keep a constant supply of dark green leaves. Sow thinly in drills a foot apart, or run a row between the peas or beans. This summer spinach grows very rapidly and is specially useful in the early summer before other vegetables are mature.

Celeriac, a turnip-rooted celery, is more easily preserved than celery and has much the same flavour. The seeds should be sown under glass (a cold frame or a cloche will do), and pricked out into a rich seed bed. When 4ins. high the plants may be put out 18ins. apart each way. The plants need plenty of water.

Bedding Plants for Summer Display.

IN the limited space of the small town garden it is of prime importance that the plants used for bedding should give a continuous supply of blooms over a long period, and many of the half-hardy annuals are specially useful in this respect. They flower in many cases right on until the frosts cut them down, and it is therefore an advantage to be able to raise seedlings under glass, so as to give them an early start. Ten-week stocks, asters, cosmea and nasturtiums are among the well known plants of this class, but there are, of course, many others.

Those who are unable to raise early seedlings of tender plants, very often purchase their summer plants from the local nurserymen or hawker's barrows. But the amateur should exercise a little caution when he makes this sort of purchase, or he may find that the plants die off, or receive a bad check, merely because they were not *properly hardened off* before they reached him. Choose plants that are short, thick stemmed, and bushy, and with foliage of a dark colour. Thin, tall seedlings with light green leaves are the result of overcrowding in the frame or greenhouse, where they were raised. If you are doubtful whether you can judge of the health of your purchased seedlings I should advise you to go to a reliable nursery for them, rather than trust to barrow dealers.

Of the plants which can be bought as seedlings and put out immediately into the small garden, antirrhinums, petunias, fuchias, pentstemons, pansies, tobaccos, stocks, lobelias and nasturtiums are some of the most popular. If the weather is dry when you receive the plants, it is advisable to water the soil before you do any planting. Do not plant immediately you have watered, but give a good soaking and then leave it for an hour or two to drain, and the ground will be in good condition to receive the plants. Make your holes rather larger than sufficient to accommodate the roots and always remember to plant firmly. Newly planted seedlings should be watered overhead after planting. Beware of late frosts. A few sheets of newspaper would give adequate protection.

Hardening Tender Seedlings.

SUDDEN changes of temperature are as harmful to plants as they are to human beings. The sheltered seedlings of summer bedding plants should be hardened off before they are planted out of doors. If you are raising asters, dahlias, stocks and similar flowers under glass, begin the "hardening off" by leaving off the light on warm days. Shut them up at night for a week or two, and then leave them uncovered altogether.

Finally, let the boxes of seedlings stand on the pathway in the open, where they can get the maximum amount of sunshine and in the event of a sudden change of temperature, can be again placed into the frame. When all fear of frost is past, they can be planted in the border.

The transplanting of seedlings seems a simple matter, yet it is one in which many amateur gardeners fail. The essential tool is a dibber, which will vary in size from a tiny pointed stick to an old spade handle, according to the size of the seedlings to be transplanted. Take the seedling in the left hand. Drive the dibber into the soil, making a hole large enough to take the roots *without doubling them up.* Hold the seedling in position, with the first pair of leaves (the cotyledons) just above the surface level of the soil. Now push in the dibber again, levering the soil against the roots of the seedling, so that it is firmly planted. In this way the seedling is put into its new quarters without being bruised by the dibber, a very important point, as bruises to the stem may cause "damping off." Asters and zinnias need great care when being transplanted.

Start Begonias Now.

IT is always surprising to me that the many beautiful varieties of begonias are not more frequently used in town gardens. They will flourish in the most unlikely places if a proper treatment is given. The tuberous root is the reason for their success in the town garden. The plant remains dormant all winter, and at this season can be started into growth ready for transplanting in June. Tubers secured now should be started in a shallow box of flaky, decayed leaf-soil and then covered with a sheet of glass or be placed in a cold frame. There is nothing better than a liberal dressing of decayed leaves in the permanent bed as well. The reason is that the begonia is surface rooted, and owing to its abnormal consumption of water to feed its fleshy leaves and flowers it needs plenty of humus in the surface soil to hold moisture. To plant begonias in a dry, arid soil is but to court disaster.

Begonias cannot stand frost, and for this reason they should have the protection of a cold frame or greenhouse, with a covering of mats on frosty nights. One of the leading seedsmen has initiated the idea of growing begonias in bowls of fibre, just as the early spring bulbs are g own. Begonias would therefore be an excellent summer plant, especially for those who can only garden in pots and bowls. The treatment is precisely the same as for the bulbs. Tubers would be planted now in fibre, and placed in a dark, frost-proof place until growth commences, taking care, of course, to keep the fibre moist.

A FINE DISPLAY OF TEN-WEEK STOCKS IN A SMALL TOWN GARDEN.

The Town Gardening Handbook.—This volume, the official handbook of the London Gardens Guild, is now published, and is obtainable from all booksellers and newsagents. The price is, cloth covers, 2s. 6d., paper covers, 1s. 6d. It is the one book for all amateurs who garden in town and suburb.

WORK IN THE FLOWER GARDEN

Clean Rustic Work.

THERE is no doubt that many garden pests, especially woodlice, are harboured by rustic work in the garden. This is usually the case when the wood is covered with bark, for then there are all kinds of crevices into which insects, etc., may creep. Where the bark has worked loose snug little retreats are provided, and in such cases the only way is to pull the bark off. Strictly speaking, it would be much better if rustic work was used without any bark at all, and in this way the number of places in which pests can hide will be much reduced. It is a very good plan early in the spring to carry out a thorough cleaning of all rustic work. For this a paraffin liquid is good, as it will kill such pests as may be in hiding. Half a cupful of soft soap may be placed in a large pail of tepid water and the like quantity of paraffin stirred in until a uniform mixture is obtained. Sponge this over the rustic work and work it into any cracks and crevices with a stiff brush. After about a couple of days the odour of the paraffin disappears.

Everlasting Peas.

THE perennial, or as they are often called, the everlasting peas, are among the most easily cultivated plants thriving in almost any situation. They are extremely useful for ornamenting bare walls, for a few pieces of a plant may be trusted to take care of themselves. The perennial peas are able to flourish even where the soil is stony and very unpromising, for the long leathery roots penetrate to a great depth. Old tree stumps, or the side of a trellis or summer house, prove admirable situations for the perennial peas and here they should only be given a minimum of training, as much staking and tying will only spoil the effect. Lathyrus latifolius, with rose-coloured blooms has some good varieties. The best of these are White Pearl, very free flowering; alba, a white variety of the old form; and Pink Beauty (delicatus), with dainty blush pink flowers. All of these are of great value for cutting. Other perennial peas which are worth growing are L. grandiflorus, less rampant, but finer in bloom than L. latifolius; the stems are weaker, but the flowers produced in pairs are twice the size. Another species, L. rotundifolia grows slower than most of the family and is of a neat habit; it is admirably suited for stony banks, where few subjects will grow. L. pyrenaicus is the most rampant of all the perennial peas and this plant will grow 20ft. in a single season, bearing prodigious quantities of yellow flowers veined with purple. L. Sibthorpi is notable on account of its early blooming, the rosy purple flowers being produced in the spring. This plant is of a dwarf habit compared with most of the other perennial peas and rarely exceeds 3ft. When well established it will form one of the greatest attractions of the spring border.—S. LEONARD BASTIN.

Cutting Back Heaths and Treatment After Flowering.

HEATHS, *ericas*, flower over a long period, and the plants, if carefully treated, live for many years and attain a large size. They are plants that lend themselves to the trainer's skill and when neatly staked and trained, look charming, as practically all the flowers can be seen at once. Untrained, naturally-grown specimens are preferred by some cultivators. There are many glass structures, owned by amateurs, that are very suitable for cultivation of the heaths in pots. I have grown them in lean-to greenhouses facing due south and with very little artificial shading; also in structures facing due east with a high wall on the west side and I am unable to say now which plants did the best, but, of course, those grown in the cooler house required the least attention. Flowers, when a fairly representative collection of plants is grown, are plentiful from early spring on throughout the summer. In a sunny structure air should reach the plants always, day and night; when the young shoots are growing they must not be drawn up weakly; they must grow wiry and steadily and at the stage when the flowers have faded extra care must be taken as regards watering. Repotting is not necessary unless the pots are so full of roots that some of the larger ones are beginning to "knuckle" on the surface of the soil in the pots. The knife must be used with great care; if, however, any cutting is necessary, it should be done when the young shoots are growing freely. If repotting is advisable, do the work soon after the flowers have faded. Be quite sure that the ball of soil and roots are thoroughly moistened before repotting and press down the new compost very firmly. Extra care must be exercised afterwards to guard against overdryness of the old ball of soil and equal care is necessary to avoid maintaining the new soil in a sodden condition. A good general compost: sandy peat, a small proportion of very fibrous loam, the rougher parts being placed near the bottom of the pot to ensure sound drainage for a long period. For young plants finely ground charcoal is beneficial and for all a light shade for a time after the repotting.—CHRISTCHURCH.

A FINE PLANT OF THE EVERLASTING PEA, LATHYRUS LATIFOLIUS.

The Sweet Fern (Myrica asplenifolia).

THE sweet fern is a first-rate shrub for a dry or semi-dry position. It is a shrub often mistaken for a fern because of its attractive dark green fern-like leaves, which are so delightfully fragrant when crushed or rubbed against. It grows only 1ft. to 2ft. high from long, hard, creeping roots, and seems rather difficult to get established. The sweet fern is best transplanted in the spring, and once it is growing will spread rapidly, proving an excellent shrub for a dry place on the rockery or to screen the nakedness at the bottom of large trees.

THE SWEET FERN IS A NEAT SHRUB FOR A FAIRLY DRY POSITION.

Myrica asplenifolia is a native shrub of Canada, where it covers dry rocky banks in profusion. It is of the same family as our own native bog myrtle.—R. MOORE.

The Climbing Hydrangea.

OF all the hardy hydrangeas—and there are more of these than most amateur gardeners realise—the climbing hydrangea, H. petiolaris, is, when mature, the most attractive. The sterile florets, relatively few in number, are widely spaced around the truss and of good size. Their colouring is that peculiar shade of greenish buff we see in the blossom of the Japanese flowering cherry variously listed as Ukon (Yukon) or serrulata luteo flore pleno. At a distance, however, a pillar of this plant in flower appears white, and in sunshine the florets do, in fact, bleach considerably. The one-year growths of the plant emit roots like those of the ivy; and the plant, when once it has formed an attachment, climbs steadily and securely on tree trunk or wall. The shrub is, perhaps, more effective on a trunk than on a wall, and a good specimen extending aloft 20ft. or more is a sight worth seeing. Moreover, its twiggy growths enable other more slender climbers to make their way up the trunk, whereas they must, otherwise, be planted so that they may climb props and so to the branches. Clematises of the Jackmanii and lanuginosa

Digitized by Google

sections come specially to mind in this connection.

Hydrangea petiolaris is particular neither as to soil nor aspect, but if planted among tree roots some special preparation should be made for it, and occasional mulchings of decayed manure are beneficial. The plant's habit of forming aerial roots makes it exceedingly easy to propagate. Pieces with roots attached inserted in a cold frame quickly become established; but a frame is not essential, for, inserted in gritty soil in the autumn, similar cuttings seldom fail to establish themselves. It is a little singular that so good a plant is so comparatively rare in gardens.—MIDLANDER.

Bedding Dahlia Paisley Gem.

A FEW years ago that bedding dahlia of the dwarf mignon type, Coltness Gem, captured the horticultural world and it was but natural to expect that the type, if we may regard it as a type, would be improved on sooner or later. That result, always desirable in progressive horticulture, is seen in the newer Paisley Gem, introduced by a Scottish firm, Messrs. Thynes of Dundee. In habit and general appearance there is little difference, but this new variety is decidedly more floriferous than the older Coltness and, in that respect, sure to become more popular. The colour is a peculiar red, described as orange scarlet; the flowers show a double row of ray petals; these petals are velvety, rich and of handsome texture. In a word, the Paisley Gem is an improved Coltness and a first-class bedding plant. Growers lucky enough to have tubers from last year may propagate freely in exactly the same way as with other dahlias. Beginners had better order plants early, as stocks are none too plentiful. As in other cases, get the plants into the frame in May and plant out during the first week in June, in ground well dug and well manured. Get the ground worked up into condition this month. The plants will show bud before planting out; the first flowers will come readily in June, and July will find the bed a blaze of colour. No staking is required, but I would point out that it pays to pick off spent flowers in this variety, as in others similar. Beyond that and with no further special care the plants will be the glory of the garden until the dahlia-destroying frosts of autumn.—CLYDESDALE.

A Fine Flowering Crab.

IN many gardens flowering trees and shrubs constitute a brilliant feature, and the flowering crabs or forms of Pyrus Malus make a bold display during the month of May. Although P. floribunda is said to be a tree upwards of 30ft. in height, we know it in gardens generally as a bush from 6ft. to 20ft., and when in full bloom it is, indeed, a glorious sight. It is a worthy subject, and is one that is suitable for all gardens. Where space exists bold groups with a dark background are suggested, but in small gardens an isolated specimen will be most effective and be a delightful change to the lilac and laburnum. The flowering crab is most floriferous, bearing clusters of pale pink flowers and crimson buds, every branch and shoot being clothed with blossom. In the variety atro-sanguinea the flowers are a deep rose, especially when fully expanded: while in purpurea the blooms are a bright rosy crimson and the foliage bronze purple. Both the type and atrosanguinea have green leaves.

These indispensable shrubs are quite hardy, and will succeed in any ordinary soil, but wherever possible a site should be chosen where there is ample space for development. Little or no pruning is required, as much better results are obtained by allowing the somewhat pendulous branches to grow unchecked. Specimens that are subjected to pruning lose their graceful outline, and the remarkable long arching shoots are conspicuous by their absence. At times a tree may be overcrowded in the centre, but this can easily be remedied by a little judicious thinning without interfering with the natural beauty of the shrub.—T. W. B.

Sow Polyanthus Primroses Now.

WE must remind readers that this is an excellent time to sow seeds of polyanthus, that delightful member of the primrose family, so prolific of blossom just now. Sow the seed in boxes in the frame or in a semi-shaded border in the open, a sandy soil suiting this purpose well. Transplant the seedlings in July or in August, into a richly manured border, where they will increase and become of flowering size in readiness to give a galaxy of blossom next year. Established plants may also be divided, to increase stock; this is done shortly after flowering during a spell of moist weather in June or July, the offsets being again put into rich soil, 9ins. apart, a partly-shaded and moist soil suiting them best. Growers who have a few choice roots ought to mark the same and allow some trusses to seed: these seeds may be sown as soon as ripe or stored until next year. Messrs. Carters have several very fine strains, including the Munstead hybrids. Dobbie's blue-flowered is worth a trial and also Sutton's Superb Mixed and Brilliance.

Two Good Sweet Williams.

TWO of the finest of all sweet williams are Scarlet Beauty and Pink Beauty. It was by the introduction of these two sorts that this branch of the dianthus family came into renewed favour; the names are indicative of the colours, but they cannot convey a true idea of the brilliancy of the flowers concerned.

Scarlet Beauty is particularly effective when seen against a vivid green background, so is ideal for a small bed set in the sunny part of the lawn. Pink Beauty is of that beautiful soft shade of pink that will tone well with most subdued shades, but more particularly so with mauve and pale blue. Good plants, therefore, to grow with Pink Beauty are linum, ageratum and mauve catmint (nepeta).

Sweet williams may be successfully flowered from a planting made during the next few weeks, and young plants should be purchased from advertisers in this journal. It is well to remember that, though sweet williams are true perennials, they are best treated as biennials, *i.e.*, raised from seed every year, May and June being the best months for sowing.—B. D. S.

An Admirable Rockfoil.

Plants can be lifted and divided now.

THE number of rockfoils in cultivation must be legion, but of them all S. apiculata is the first to unfold its flowers. Much depends however on the mildness or otherwise of the season and when the weather is favourable spikes appear early in the year from March onwards. So early a bloomer should be planted in fairly large patches and in a variety of positions, whereby the flowering period would be extended. Although repetition is not recommended in the rock garden generally, one exception can surely be made with an early flowering subject, especially when it is possible to have a large drift or colony with little trouble or expense. Most gardeners know that it is the early morning sun that often creates the damage after a frost, so one patch should be planted where they will be sheltered from the early sunshine, and in most instances the flowers will suffer no damage. It forms a mat of dark green foliage and the yellow flowers, several together, are produced on stems from two to three inches in length. A white flowered form appeared a few years ago and is known as alba. This is equal to the type in every respect, and will be welcomed by those who enjoy white flowers and variety.

Like many other members of the genus, the secret of successful cultivation lies in occasional division, and this becomes a necessity when a clump has become somewhat congested and formed a mound. As a rule the plants are lifted, divided, and replanted every third year. Fairly deep and firm planting is advised and those patches not needing division may be top-dressed annually with soil working the compost well between the growths. Soon after flowering is a good time for affording the plants attention in regard to soil.—T.

A DOUBLE EDGING OF POLYANTHUS PRIMROSES IN A SHADY BACK GARDEN.
These are in full flower now and can be used effectively for bordering a grass path. Seeds can be sown during the next few weeks or the plants divided after flowering.

LOW RETAINING WALLS and their CONSTRUCTION

Such walls can be made a distinctive feature of many a small garden if carefully constructed and planted with suitable subjects.

THE planning and planting of the garden about a house that is built upon a hilly or sloping site presents many little problems which can be solved by the use of retaining walls, which, at the same time, contribute a charming and distinctive feature to the result when such walls have been in position a year or so. Naturally, no matter how skilfully their building has been carried out, these walls present rather a stark appearance for the first few months of their existence.

In the planning of these sloping sites one must leave banks of soil which will not remain in position owing to erosion by weather. Lawns have to be levelled, paths cut, or sunk gardens made, all of which leave on one or more sides an embankment of soil which must be kept in place by some mechanical means. If the bank of soil is small, the earth may be kept in position by a retaining wall of logs laid parallel with the border, and others driven well into the bank of earth with the butt ends resting on those below. If these logs are left without stripping off the bark, they look very unobtrusive, and furnish plenty of crevices in which plants may be inserted.

The kind of material used for the retaining wall will largely depend upon the cheapness of the material which can be obtained locally. Stones, although they make the most effective walls, are extremely heavy, and, while appearing cheap at the ton rates quoted by the quarries, are really excessive when the cost of carriage is added. The prettiest stone which I have seen used for this purpose is a kind of grey shale used largely in the Westmorland Lake district. No two pieces appear exactly alike; some are a pure grey, others have a pinkish hue, while some are almost olive green. Time weathers this stone to a lovely velvety grey, which is still further enhanced when the mosses and lichens grow upon them.

Bricks can be obtained everywhere, and, provided they are not of a glaring crude red colour, make a very effective wall which resists erosion almost indefinitely. Bricks, unfortunately, are rather costly as a wall material, although where expense has not to be considered they are excellent. Bricks may be laid along the top of walls of other materials where a straight line is desired. These may either be mortared or left with soil placed between them, giving plants an opportunity to spread their roots and to hold them as firmly together as could be done by mortar.

When stone is used, dry-wall construction lends itself well to plant culture. Large and small stones, which may be obtained from the site in certain districts, may be used in the same wall, the smaller stones holding the larger ones in place with the wedging action and the soil which in time fills the interstices. In such a wall it greatly helps if the bank of soil is sloped gently backwards, against which the stones can rest. Flints are not to be despised if reinforced by a cement mixture made of cement one part to sand five parts. This is either pointed into the wall after erection, or the flints or small stones can be laid in a dab of the cement mixture applied to the stone on

A CEMENT BLOCK WALL THE CONSTRUCTION OF WHICH WAS DESCRIBED IN OUR LAST WEEK'S ISSUE, SHOWN PLANTED UP WITH AUBRIETIA, AND AN EDGING OF CATMINT SIX MONTHS AFTER LAYING.

SHOWING THE CONSTRUCTION OF A LOW WALL MADE OF FLINTS.

Digitized by Google

which it will rest. If a fairly rough surface is left on the cement, *i.e.*, it is not trowelled, soil will lodge and mosses grow, which greatly add to the appearance of such a retaining wall. Where possible, plants should be inserted at the time of building any wall, setting the roots well back in the soil where they may obtain the necessary moisture and nourishment.

Walls constructed of cement blocks are clean and strong, contrasting well with most of the plants which will grow in such positions. Full details of the making of a wall from cement blocks were given in an article last week. Again, it is better to put in the plants as the blocks are laid, it being very difficult to insert the roots once the blocks are placed in position. Seeds of the hardier alpines may be inserted in such crannies, it is true; but the owner of a concrete wall will be in a hurry to break its crudeness by means of mature plants. If good, strong seedlings of alpines are taken from pots, the wall will present quite a finished appearance some six months later.

Much depends upon the situation of such walls as to the plants which shall be inserted or grown along the top to hang down and cover them. The shady wall may have primroses in the crevices, or the creeping periwinkles, or similar trailing plants trained to hang down. Aubrietias do very well in a wall which gets a little sun, and so do the cerastiums or arabis.

I prefer to plant up such walls with one variety of plant, such as aubrietia, which gives a foaming mass of colour all along the wall from April to June, and, if cut back after flowering, furnishes the wall with the new growths which rapidly push forth.

CLARENCE PONTING.

INSECT PESTS OF GARDEN PLANTS

WITH the approaching days of spring one looks forward to the awakening of plant life, which is accompanied, unfortunately, with the awakening of insect life. For the purpose of studying the pests which may be expected to attack ornamental plants, I have grouped them under four headings, *viz.*: (*a*) Pests of annuals; (*b*) pests of herbaceous plants; (*c*) pests of bulbs and tubers; and (*d*) pests of ornamental trees and shrubs. The majority of the pests belong to the group Hexapoda, or true insects; but there are others equally important, such as mites (of which the common "red spider" is an example), gall mites, millipedes, slugs and snails and eelworms.

Many new species of plants are being continually introduced into our gardens from China and elsewhere, and careful watch should be kept on them for the presence of pests, as they are equally liable to attack by indigenous species of phytophagous insects.

Prevention Measures

The old adage "Prevention is better than cure," is specially applicable in the flower garden, and a great deal can be done to prevent the presence of pests. Clean cultivation includes many hygienic principles which should be attended to assiduously. One of the chief reasons for the presence of pests is that weeds are allowed to grow and flourish not only in flower and shrub borders, but more particularly in waste ground in proximity to hedges and ditches; while hedge plants (quick or hawthorn) "carry over" many insect pests of ornamental trees and shrubs. The elimination of these "nurseries" should be aimed at by destroying weeds and keeping the borders and waste land constantly hoed; while hedge plants should be watched for the presence of green fly (aphides) and caterpillars and treated accordingly. Under hedges and in various parts of the garden, rubbish (*e.g.*, leaves, grass cuttings and dead herbaceous plants) accumulates and provides ideal hibernating quarters for weevils, woodlice, slugs and snails. All dead and decaying plants and parts of plants should be stacked and limed. Prunings and dead branches cut out of trees and shrubs should be burnt and not left lying about on the surface of the soil around the plants, for on shoots can be found the eggs of various aphides, scale insects and moths, and in dead branches can be found many bark beetles and boring insects. Old paint tins, insecticide cans, broken flower pots and brickbats should be either buried or used as a foundation for garden paths, as they provide admirable retreats for slugs and snails. Wooden boards used as edgings to flower borders are satisfactory so long as they are preserved, but when they commence to decay they attract woodlice, which do not restrict their attentions to the wood but feed on the foliage of many plants.

PESTS OF HARDY ORNAMENTAL PLANTS AND THEIR REMEDIES.

A.—ANNUALS.

Pest.	*Symptoms of Attack.*	*Host Plants.*	*Remedial Measures.*
Green fly (aphides) ..	Curled leaves; growing points infested with "fly"; sticky exudations on foliage, followed by the growth of black mould.	Most annuals.. (sweet peas)	Spray as soon as the pest is observed with nicotine, quassia or derris.
Thrips (thunder fly) and "red spider."	Mottled foliage and distorted flowers.	Most annuals.. (sweet peas)	Constant syringings with clear water. Use nicotine wash in heavy infestations.
Caterpillars of moths and false caterpillars of sawflies.	Foliage eaten entirely or skeletonised.	Many annuals.. (tropæolum)	Hand-picking; light sprayings with lead arsenate
Surface caterpillars (Yellow Underwing and Turnip moths), and leather-jackets.	Plant wilting and heeling over. Damage below or at surface of soil.	Many annuals.. (marigolds).	Hand-picking; trapping with bait of potato or mangel. Hoeing in soil insecticide.
Slugs and snails	Seedlings eaten off; foliage of larger plants devoured; presence of slime indicates their presence.	Most annuals ..	Hand-picking; trapping with orange peel and lettuce; dusting plants with various proprietary materials.

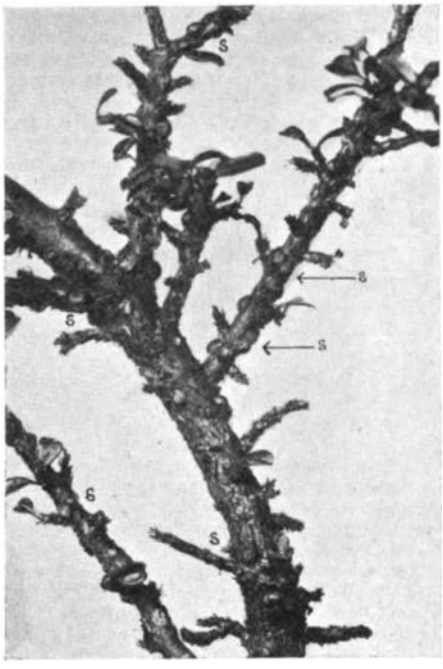
B.—HERBACEOUS PLANTS.

"Cuckoo-spit"	Wilted growths. Immature insects covered with spittle-like exudation.	Many, especially geums, campanulas, solidago.	Spray with nicotine and soap, using good pressure in order to break through protective covering of insect.
Moth caterpillars (Silver Y and Angle-shades); sawfly caterpillars.	Foliage eaten entirely or skeletonised.	Pelargoniums, primulas, Solomon's seal, spiræa, iris.	Hand-picking; lead arsenate spray.
Surface caterpillars, leather-jackets, weevil and chafer grubs.	See "Annuals"	Many, especially chrysanthemums, polyanthus.	Hand-picking; injection of carbon bisulphide; apply soil insecticides.
Slugs and snails	See "Annuals"	Most, especially delphiniums, lupins.	See "Annuals."
Woodlice ..	Holes eaten in foliage ..	Many	Trapping with hollowed-out potatoes; liming soil.
Stem eelworm	Foliage distorted; growth either stunted or elongated; stems cracked.	Phlox, campanula, wallflower, sweet peas.	At first signs of attack cut out sickly plants and burn; refrain from growing same plant on infested land for three years.

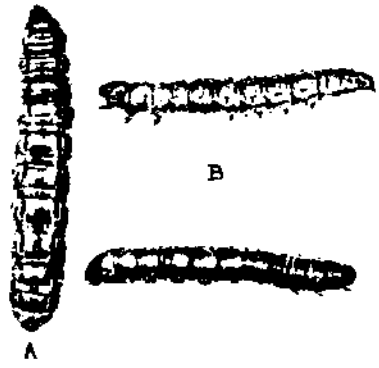
Remedial Measures.

Severe criticism is often levelled against the efficiency of spraying, but it is always found that the human element is at fault. Some of the causes are (1) inefficient spraying machinery (poor pressure and faulty nozzles); (2) careless spraying—*i.e.*, applying the wash to the wrong part of the plant (the rhododendron bug is always and aphides are generally found on the lower surface of the leaves):

Digitized by Google



ROUND OR PEACH SCALE ON COTONEASTER TWIGS.



SURFACE CATERPILLARS OR CUTWORMS.
(A) *Yellow underwing moth*,
(B) *Turnip moth*.

TYPICAL WEEVIL DAMAGE ON RHODODENDRON LEAVES.

(3) inattention to the type of pest present on the plant, with the result that a stomach poison (lead arsenate) is used against insects with sucking mouthparts, such as aphides, scale insects and capsid bugs; and (4) dilatory application, *i.e.*, allowing a pest to become numerous before an attempt is made to combat it: one should aim at killing the ancestors, not their descendants!

Spraying is only one of the numerous control methods which can be carried out in the flower garden. Other efficient means of combating pests are: hand-picking caterpillars on foliage and surface caterpillars in the soil, weevil grubs at roots of plants slugs and snails; trapping leatherjackets, wireworms, millipedes and woodlice with pieces of potato, beetroot or mangel, and slugs with cucumber or orange rind; jarring plants over white paper or greased boards to capture leaf-eating weevils and chafers; pruning off egg-masses of vapourer moth, egg rings of lackey and March moths, and clusters of the black shiny eggs of aphides on species of pyrus, cratægus and cotoneaster; injecting carbon disulphide into the soil for root aphides, weevil grubs and other soil pests, and constant disturbance of the soil by hoeing to kill surface caterpillars, leatherjackets and millipedes.

Insecticides.

There are four types of insecticides which should be used in gardens. They are: (1) Winter washes, for use in the dormant season on deciduous trees and shrubs (caustic soda for clearing them of algæ and lichens which harbour many pests, and tar distillate washes for destroying the eggs of aphides, psylla and scale insects); (2) contact washes—nicotine and soap, quassia and soap, and derris—for combating sucking insects (aphides, leaf-hoppers, young scale insects); (3) stomach poisons—lead arsenate—against biting insects (leaf-eating caterpillars of moths and sawflies, weevils, chafers and woodlice); and (4) soil fumigants—carbon bisulphide—for weevil grubs and chafer larvæ, and soil insecticides—naphthalene—for leatherjackets, wireworms and surface caterpillars.

Insecticides should be obtained in a form ready for use and always mixed with soft water. It is unwise to spray plants in bright sunny weather for scorched foliage will invariably result from such a practice; and it is better to choose a dull day or apply the wash in the early morning or late in the evening. Spraying materials should be purchased from reliable firms, and to attain this end the advertisement columns may be studied with advantage.

The tables given enumerate the more common pests of hardy ornamental plants

G. F. W

PESTS OF HARDY ORNAMENTAL PLANTS AND THEIR REMEDIES—*Continued.*

C.—BULBS AND TUBERS.

Pest.	*Symptoms of Attack.*	*Host Plants.*	*Remedial Measures.*
Aphides ..	Yellowing of foliage, sometimes accompanied by curling.	Tulips, dahlias.	Spray periodically with contact wash.
Surface caterpillars.	See "Annuals"	Dahlias ..	See "Annuals."
Large and small narcissus flies.	Yellowing of foliage, bulb rotting, with one or more larvæ inside.	Narcissus, hyacinth, scilla, leucojum.	See under "Stem eelworm."
Stem eelworm	Foliage and flowers distorted; growth stunted; concentric black rings on cutting bulb through.	Narcissus, hyacinth.	Destroy badly infested bulbs; slightly infested bulbs should be immersed in water at 110° Fahr. (43° C.) for three hours in early August.
Millipedes ..	Bulbs and tubers bored, with subsequent rotting.	Tulips, dahlias.	See "Woodlice" in B.

D.—ORNAMENTAL TREES AND SHRUBS.

Aphides ..	Curled or reddened foliage, sometimes accompanied by leaf fall; sticky exudations on lower leaves.	Species of pyrus, prunus, cotoneaster, berberis, Sitka spruce, etc.	Frequent sprayings with contact washes; early applications are essential.
Woolly aphides	Cankerous growths and twisted growths.	Pyrus and pyracantha species.	Nicotine soap wash applied with great force to ensure penetration.
Scale insects ..	Stems encrusted with scale-like growths; young insects on foliage and shoots. Woolly form on stems of beech.	Pyrus, prunus, cotoneaster, beech.	Winter wash on deciduous species; nicotine soap wash applied to foliage and stems in May; scrubbing stems and main branches of beech with caustic-paraffin emulsion.
Caterpillars, chafers, weevils.	Leaves eaten entirely or partly.	Most shrubs ..	Lead arsenate wash in early May; jarring branches on dull days over paper or boards for chafers and weevils.
Red spider ..	Mottled foliage, often accompanied by leaf fall.	Pyrus and other trees.	Frequent sprayings with clear water, nicotine soap wash or sulphur dustings in bad infestations.

WHAT OUR READERS SAY

THE PEACOCK IRIS, MORÆA GLAUCOPIS.

SIR,—Can any reader with experience of this exquisite irid tell me what I am to do to get blooms? I have tried all kinds of conditions, both indoors and out, but have hitherto failed to obtain more than one or two flowers out of every hundred bulbs. It is usually listed under the name of Iris pavonia, the Peacock Iris.—S. BROWNING SMITH, *Otford.*

AN ENCROACHING ROCK PLANT.

SIR,—In your issue of the 2nd inst, under the heading "Low-growing Rock Plants," I notice Helxin: Solierolii mentioned. A warning is added that it is an encroacher and undoubtedly it is a most dangerous plant to introduce into a rockery.

Helxine has given me trouble for years. I have used bushels of salt in trying to destroy it in the retaining wall of a stream bed.

Arenaria balearica is far less dangerous, much prettier and will cover a shady path or wall very quickly.—R. H., *Weymouth.*

APPLES FOR SANDY SOIL.

SIR,—I planted, some twenty-five years ago, three Beauty of Kent, one Newton Wonder and one Bramley Seedling apple trees—all standards. I consider that each Beauty of Kent tree has borne at least double the amount of fruit carried by either of the other varieties named. Further, they have kept with me quite as well and as long as those of Newton Wonder and Bramley Seedling, and I find them to cook quite as well, while as bakers they are much better. I still have by me some Beauty of Kent apples in good condition. My soil is quite sandy. Standard Marie Elizabeths have done well for a variety which is not classed as a heavy bearer, but as croppers much below Beauty of Kent.—T. G., *Nottingham.*

A BLUE FLOWER FOR THE BORDER, THE CYNOGLOSSUM.

SIR,—I am pleased to see that "T. W. B." has a word of praise on page 232 for this very beautiful but all too little known biennial, the cynoglossum. It only needs to be grown to be widely appreciated, as it is just as easily raised from seed as a wallflower. My experience of it, however, during winter is that it is uncertain in cold exposed localities, but that can be got over by lifting plants into a cold frame for the winter, giving as much air as possible. Friends of mine in the midland counties have not been able to keep it unless given the shelter of a frame, but, treated much in the same way as pentstemons and given frame room, they have come through all right. I have during the past winter lost rather more plants from an outside bed, the fewest losses being among plants planted out close up to a wall on a south border. Still, with this, the cynoglossum, with its delightful blue spikes of almost forget-me-not flowers, is worthy of a place in every garden. Sown in June or July, as "T. W. B." suggests, plants will be right for blooming in June the following year. How is it so few gardeners know anything about a plant so beautiful, I wonder?—W. LINDERS LEA.

ESCHSCHOLTZIAS.

SIR,—With reference to Mr. Bailey's article on "Eschscholtzias" in your April 2nd issue, if the ground is not available, or for some reason it is not desired to sow in the open, I have found eschscholtzias can be quite easily raised by sowing two or three seeds in a small 60 in a cool greenhouse or cold frame, and planting out when the roots have got to the bottom of the pot, taking care to plant intact without disturbing the roots. When I have any special variety and only a small quantity of seed, this is the way I always do and I never have any difficulty at all.

Another piece of useful information about the eschscholtzia is that it is one of the simplest of "annuals" for autumn sowing in the south of England, as it can be sown in the open where intended to flower in suitable weather towards the end of August, and I never have the slightest difficulty in getting them through the winter. An important point to remember is that the situation should be sunny, open and well drained. They will stand considerable frost.

The eschscholtzia is undoubtedly one of the easiest plants to grow and one ought never to have any trouble whatever in raising it from seed. In fact, in most cases I should think the main difficulty is that it will probably be sown too thickly, with the risk that if not thinned out sufficiently the plants may smother themselves.—A. BALFOUR, *Sutton's Trial Grounds, Slough.*

A MARCH GARDEN.

SIR,—While crocuses, snowdrops, eranthis, early irises and other brave things brighten the garden and bring promise of spring to the heart of the gardener, perhaps even a greater pleasure may be obtained by laying out a special plot as a complete little garden to produce a lovely patch of colour at this early period of the year. Mine is some three or four square yards in front of a window facing east, and the soil, a chalky clay, is not of the best, so climatic or soil conditions need deter no one. The background of dwarf evergreens of contrasting colour consists of Cupressus Fletcheri, Erica carnea (pink), Retinospora ericoides and Veronica lycopodioides. Also, a couple of the old purply pink Daphne Mezereum. The carpet is provided by the violet cress, Ionopsidium acaule, and, through this, springs an irregular mixture of Iris reticulata and Crocus Tomasinianus: a dream of purple, lilac and pink.

The cress is continually producing fresh seedlings and is in bloom the whole year round. It has bloomed profusely all through the present winter absolutely unperturbed by frost or snow. Quite apart from its particular charm in March, this little garden remains an object of beauty in subdued colouring for the rest of the year. Another plant I omitted to include above is Saxifraga oppositifolia. I am now contemplating another March garden, starting with Kaufmann's tulip and the blue Anemone blanda. Will some braver spirit plan for us a little February garden with Iris Histrio and the early snowflake?—B. S., *Kent.*

SPRAYERS AND SPRAYING MACHINES

THE importance of spraying is obvious to all gardeners, professional and amateur alike, and with the numerous types of sprayers already upon the market, a few words upon the types that have proved the most efficacious of their kind should be of considerable interest.

Having divided these into three classes, namely, (1) Hand sprayers and syringes, (2) Bucket sprayers, (3) Pneumatic sprayers: let us turn our attention to the former, which, of course, is by far the most popular of them all. The various types of hand sprayers in use at the present time are numerous and it is somewhat difficult to single out any particular one as being vastly superior to another. Three that are worthy of special consideration, however, from the amateur's viewpoint, are Carters' "Ideal" hand sprayer, and "Abol" and the "Four-Oaks" garden syringes. As will be seen from the illustration, the "Ideal" sprayer consists of a copper container holding two or three pints, according to size, with plunger attached, so that the user can spray the whole greenhouse or a large number of trees without having to carry the insecticide about, as in the case of the ordinary spray syringe. The perfect mist spray produced will not hurt the most tender plants.

THE PERFECT MIST-LIKE SPRAY GIVEN BY THE "IDEAL" SPRAYER.

The chief features of the "Ideal" sprayer are as follows:

1.—It can be used for spraying rose trees and fruit trees alike, as it produces three different types of spray, all of which are obtainable from the one nozzle.

(*a*) The perfect mist-like spray for spraying rose trees and for general greenhouse work.

(*b*) The mist spray for spraying fruit trees, carrying to a height of 25ft.

(*c*) A long, thin jet, carrying to a height of 30ft.

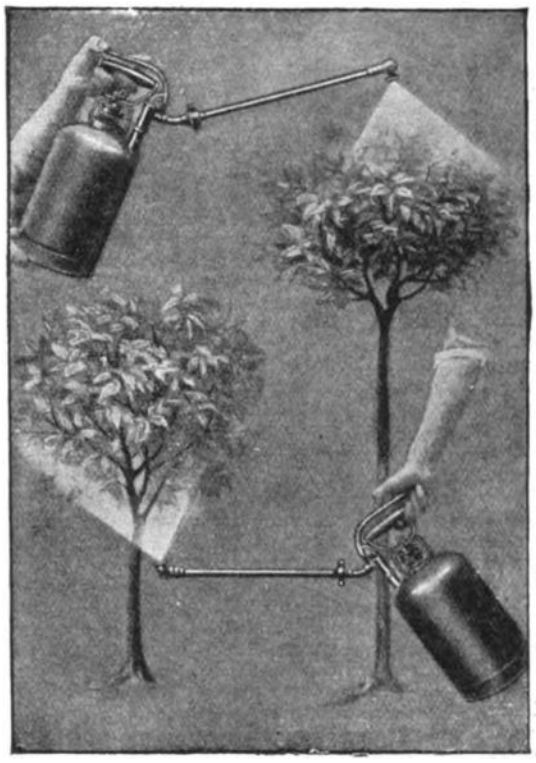
2.—The force with which the insecticide is penetrated into the plants and the perfect mist-like spray obtained make it ideal, both from the point of efficiency and economy.

3.—The two-pint model gives 100 sprays. Copper and brass extensions are also supplied so that the insecticide can be sprayed underneath the leaves of plants and also carried to a greater height.

For the convenience of growers on a large scale the "Ideal" sprayer is also supplied in a knapsack form, the container of which holds two gallons of solution.

Abol syringes have been known and used in gardens for many years. They are excellent for spraying greenhouse plants, roses, wall fruit trees, etc. The fine spray which they

Digitized by Google



A PNEUMATIC HAND-SPRAYER, THE "HOLDER-HARRIDEN," SUITABLE FOR SPRAYING SHRUBS.

discharge with great force is very effective in keeping down attacks of red spider and aphis. The "Four-Oaks" syringe is also highly efficient and is invaluable in the garden as well as the greenhouse. Both these syringes can be supplied with angle-joints, by means of which the under sides of leaves and branches can be sprayed effectively.

The bucket sprayers are very popular with a large number of people owing to the many uses to which these can be applied. Not only are they useful in the spraying of rose trees, fruit trees, etc., but they also form an ideal apparatus for lime washing poultry houses, sheds, garages, etc.

Here again there are several types from which to select.

The "Eclipse" sprayer is one of the simplest and most efficient sprayers upon the market. It is a hand sprayer which is used in conjunction with a bucket. There are no intricate parts to get out of order and, as no pumping is necessary, the operator has both hands free to direct the spray.

The number one "Eclipse" sprayer consists of sprayer complete with 2ft. lance, polished and lacquered, 10ft. rubber hose and strainer, special liming nozzle and swivel angle bend, with adapter for overhead spraying of fruit trees.

The "Eclipse" is to be recommended for general use in the garden, and for lime washing. It is easy to manipulate, light and very portable.

The distinct advantages of pneumatic sprayers over hand sprayers are, of course obvious to all, no continuous pumping and both hands free. This is, of course, a favourable asset where there are large areas to be treated.

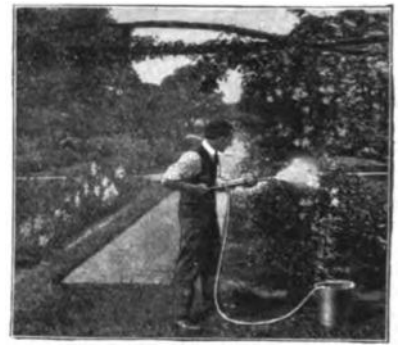
The "Four-Oaks" pneumatic sprayers and lime-washing machines are very reliable and give good service for a considerable number of years.

Another well known firm which manufactures spraying machines for all purposes is Messrs. Robinson Bros. Their sprayers are made in all sizes, the smallest of which is very suitable for use in the amateur's fruit garden.

The "Martamith" pneumatic sprayers are particularly useful for spraying and lime washing in the small garden. Knapsack as well as hand sprayers are made by this firm.

Of the many various types offered, details are given of one, the "Holder-Harriden."

"Holder-Harriden" sprayers are now only made in Virex Brass Alloy, a metallic compound to a special formula that can be used, and will resist, not merely ordinary non-acid compounds (soap and quassia, nicotine, coal-tar fluids, etc.,) but also the stronger fluids: copper sulphate, caustic soda and particularly lime sulphur and liver of sulphur. The last



THE "ECLIPSE" SPRAYER IS ADMIRABLE FOR ALL GENERAL PURPOSES.

two quickly attack copper machines, and these are also not immune to caustic washes.

Each machine is fully tested. The larger sizes will stand a test of 300lb. pressure to the square inch, in practice 70-75lb. being ample to discharge the whole of the contents in a very finely divided misty spray. There is but little slackening of power at the finish.

The working is simplicity itself and, with an entire absence of intricate mechanism, there is nothing whatever to get out of order. All parts are readily accessible for cleaning, etc., and with a little attention even the plunger-leather will not require renewing for many months or even years.

There are no loose parts to get lost or mislaid and, particularly, the pump is always in its place.

Compressed air is a powerful force and pneumatic machines of weak or careless construction are to be avoided at any cost.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

Pricking Off Seedlings.

This method will prove both speedy and highly successful in the pricking off of such small seedlings as begonias, streptocarpas, etc. Well crocked pans are filled with a light compost, with a finely sifted layer on top, and just lightly watered (not soaked) with tepid water; this makes the firming of the seedlings easier. The tedious pricking off of such small seedlings will be much facilitated if an ordinary 6in. wood label be used to pick them up, they having been previously loosened. If the label be held in a vertical plane and the pointed end wetted it will be found that the seed-leaves adhere quite readily to it, and the seedlings are then easily transferred to the pan and made firm by a dibber held in the other hand. It is advisable to water from "beneath" until the seedlings are well established.—W. E.

Damage to Young Pea Plants.

Young pea plants which have just appeared through the soil are subject to leaf-eating pests. Frequently this damage is attributed to birds. When this is the case, pea guards, cotton, etc., serve to ward off the attack. Should the attack continue in spite of pea guards, a close and very careful inspection must be made of the plants and the soil surface. Such an examination usually reveals the pea weevil. This weevil is only about one-fifth of an inch in length, soil-coloured, a night feeder, and, when disturbed, falls to the soil, hence the reason for diligent searching of plants and soil and also why the attack is usually proclaimed as being due to the ravages of birds. Remedies for the pea weevil are: (*a*) spraying the young plants with weak arsenate of lead; (*b*) dusting the plants when moist with hellebore or pyrethrum powder, or a mixture of soot and lime. Avoid sowing in the same place next season. —J. H.

An Outside Shelf for Sun-baking Plants.

Azaleas, after flowering, require all the sun possible to ripen wood for next year's flowering. Against a wall facing south two stout pieces of wood are rammed into the soil and another broad piece nailed on the top of these pieces to form a shelf. Other pieces of wood can be nailed to this shelf to form a lip all round to hold leaf mould and moss, into which the pots are plunged. This latter keeps the pots moist and minimises the need for watering. Often azalea pots are plunged into garden soil, but this is unwise, as a fair quantity of lime is in this soil and azaleas dislike it. Not only can this shelf be used for azaleas, but for pelargoniums after flowering, and many other plants and bulbs. This shelf is better than putting plants simply on ground, because often other things which are growing shade them. Especially is this shelf useful in a small garden where there is not much room.—H. G.

Sowing Small Seeds.

Before sowing small seeds, such as begonias, after the pans have been filled and soaked take a handful of dried sphagnum moss and rub it through a fine wire sieve such as is used in kitchens until the surface of the seed pan is covered to about an eighth of an inch deep, sprinkle a little sand on top, then the tiny seedlings will lift with a nice little ball when large enough to prick off.—G. R.

The Surface of Asparagus Beds.

Obtain some old mortar rubble, put this through a ½in. mesh screen, to every barrow of screened rubble add half a barrow of builders' red sand, mix well together, give the beds a liberal dressing in the spring, about a barrow to 10yds. or 12yds., fork lightly into the surface of the beds. One bushel of wood ashes screened through a ½in. mesh to every barrow could be added, also a little bone meal, if desired.—G. W. B.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

ALTHOUGH activity in gardens and allotments is now general, outdoor operations are in arrears in various localities where the land is heavy and in an unworkable condition, resulting from the wet weather experienced in inland districts. The temperature in April has, so far, compared unfavourably with that of March and occasional heavy hail showers have neutralised the effects of brief spells of sunshine. Seasonable work, such as the sowing and planting of vegetables, rose pruning, etc., has therefore been interrupted from time to time, while growth is less rapid than it was a few weeks ago.

In the course of a lecture on roses, given under the auspices of the Hamilton Horticultural Society the other evening, I had occasion to comment on Golden Emblem's well known fault of dying back in winter. During the discussion which followed a member of the audience took exception to the statement and confidently asserted that in no district in Scotland would that defect be seen if the plant received a good top-dressing of manure in late autumn. Along with many other rosarians my experience of that once popular yellow Pernetiana has been unfortunate and it would be interesting to learn how Scottish readers of THE GARDEN have fared in that respect as any treatment that would be the means of imparting vigour and prevent the loss of the rose would be welcomed by every class of grower. Personally I "hae my doots" regarding the efficacy of winter manuring, because, as the result of many years experience I am of opinion that the weakness is constitutional.

There is abundant evidence that Golden Emblem is losing favour with the public as a rose for general garden cultivation. Nurserymen in Scotland who specialise in the raising of roses tell me that there is a falling off in the demand, and in a recent plebescite organised by a Glasgow paper, Golden Emblem was displaced in the collection of twelve varieties by Mabel Morse. Moreover, I notice in the National Rose Society's analysis for 1926, northern amateurs preferred Christine Mabel Morse and Mrs. Wemyss Quin to Golden Emblem which is placed sixteenth on their list. In several rose catalogues the fact is emphasised that it does die back very badly.

Few plants which contribute to the decoration of the garden have come into greater prominence in the past few years than catmint. Like several other favourites of our boyhood days, that hardy native of the Caucasus went out of fashion in modern gardens, but its useful qualities are again being recognised each successive year, until it has become almost as familiar as the Coltness Gem dahlia, with which it is frequently associated. The carpet of silvery grey foliage makes a beautiful setting to the fragrant soft lavender blue flowers which bloom profusely throughout the summer season into autumn. It is most accommodating in regard to situation and although it makes a pretty clump in the herbaceous border and likewise adorns the rock garden in the form of knolls, catmint is most effective as an edging to a mixed flower border, where it can encroach on the adjoining gravel path with pleasing irregularity. While it thrives in almost any garden soil, it prefers a light or sandy rooting medium in a sunny position, for there the grey foliage takes on its finest colouring. Autumn struck cuttings are available at the nurseries and when planted in late April or early May will grow and flower freely in the coming season. Stocks may be easily increased in autumn by taking cuttings with a "heel" and inserting them in sandy soil in a frame, where they root readily.

The amateur's greenhouse is seldom considered complete without a few tomato plants that will provide supplies for the household during late summer and possibly into September, if there is sufficient sunshine to ripen the upper trusses. In our uncertain climate the element of risk usually accompanies early planting in an unheated greenhouse, while on the other hand delay means the later maturing of the fruits and limitation of the crop. The happy mean is probably to be found in the early days of May, but even then the influences of weather and locality should be taken into consideration. The ideal tomato is a short jointed plant that produces an average crop of medium-sized fruits of good flavour, but the amateur who does not grow his plants from seed and depends on a local nursery for a small supply, has frequently little choice outside of popular market varieties, such as Ailsa Craig, Kondine Red, etc. Soil that is too rich is harmful, as it produces soft, rapid growth. Assuming that the plants are to be grown in pots or boxes, a suitable compost would consist of six to eight parts of loamy soil, according to quality, and one part manure, with 1lb. of bone meal added to a barrow load, but amateurs should never forget that a good crop of pot or box-grown tomatoes depends more on surface feeding than the ingredients in the soil in which they are planted. During the early stages of growth watering should be restricted to the actual necessities of the plant, but as soon as the flowers on the first trusses begin to open, the soil may be thoroughly moistened and from that time water should be given as often as required, as a dry soil is detrimental to the setting of the fruit and plant development. All side shoots should be pinched out as soon as they appear, especially the large shoot which pushes from the leaf joint immediately below the truss. A good fertiliser for pot tomatoes consists of two parts nitrate of potash, six parts superphosphate and one part sulphate of ammonia. For twelve plants in pots apply in the ratio of 2oz. to 3 gallons of water once a week. Until warm weather sets in the ventilators of the greenhouse should be closed in the late afternoon in order to maintain a moderately higher temperature at night.

FRUIT AND KITCHEN GARDEN

Transplanting Small Seedlings.

HUNDREDS of thousands of seedlings of vegetables are now being transplanted in every district throughout the country. All, however, do not survive the operation. Even when the work is carried out by experts there are losses, so it is advisable to transplant more than are actually required to make allowance for the losses. But be careful not to crowd the seedlings unduly in order to have a reserve as the overcrowding would result in weakening all. First, in regard to transplanting seedlings in boxes. The latter should have holes in the bottom or the boards should be nailed on so that there is a space about half an inch wide between them for ensuring drainage. At this season the boxes should not be less than 5ins. in depth. In the bottom of boxes for vegetable seedlings some well rotted manure will be beneficial to them. The same plan should be adopted when transplanting seedlings and young plants in beds in frames. In the open nursery bed the rotted manure should be dug into the ground well mixing it with the soil generally. In these nursery beds many of the winter vegetable crops are treated and the transplanting of them at about 4ins. apart, leaving them so for about six weeks and then removing them to their final quarters with plenty of roots and a lot of soil adhering means success.—HANTS.

Climbing Butter Beans.

WHEN, as often happens in a small garden, just one row of runner beans is sown early in the season, the crop may end rather suddenly and some weeks before the ordinary autumn and winter vegetables are available. In such cases attention may be directed to the value of the climbing butter beans, which are usually listed under the name of Mont D'Or. These beans come quickly into bearing, and they have the additional advantage over the others of being all edible and, in fact, they can be cooked whole for the membrane or skin which is a feature of the ordinary bean is entirely absent. These butter beans, although they are early croppers, have a long season of production, and will continue bearing until November in a favourable autumn. The seeds, which should first be soaked in warm water for a quarter of an hour to hasten germination, may be sown in May. Very good results are secured by sowing a proportion of butter beans in with the ordinary runner beans. The butter beans are much less robust in habit than the ordinary kinds, and will confine their growth chiefly to the lower parts of the sticks. Later in the season, when the runner beans are nearing the end of their cropping, some of the thick leafage above may be removed in order to let more light in to the butter beans.—C.

You May Still Sow Broad Beans.

THE broad bean is one of the hardiest of our vegetables and it is customary in some districts to make sowings in the open ground in November, while January and February are the usual months for sowing the main crops of this splendid vegetable, the object being to obtain pickings as early as possible and until such times as early peas and runner and dwarf beans are obtainable.

It is well to note, however, for the benefit of those not inconsiderable few people who possess a special fondness for a dish of broad beans that a succession may be maintained and later supplies obtained by making sowings at intervals up to the end of April.

No vegetable is more easily grown by the amateur or even beginner at gardening. It prefers a somewhat retentive and moist soil, but does well in almost any ordinary garden soil, while for planting on newly broken-up land it proves very useful. Sow in single rows 2ft. apart and allowing a distance of 9ins. between each plant; an alternative is to sow in double rows, allowing a distance of 1ft. between each line, forming the double row and 3ft. between each double row.

Hoe frequently during the growing season and keep a sharp look-out for attacks of black aphis. This may be kept in check by syringing with soap and water to which a little nicotine has been added.

When the plants have attained sufficient height and have plenty of bloom on them,

Digitized by Google

pinch out the tops, this removes the tender portion which the aphides attack and also assists the pods to swell.—T. H.

How to Treat Young Cucumber Plants.

CUCUMBER plants thrive in heat and moisture and perish in a moist atmosphere and a low temperature. It is during the early stages of growth that the greatest difficulty with them is experienced; we have spells of very cold weather, especially during the night-time and, as artificial heat is not always available in unlimited quantity, matters are made worse. I strongly advise amateurs who are not able to command artificial heat, to make use of a small frame or box inside the glass structure, whether the latter be a greenhouse or a garden frame, and place the young pot plants in it until the time comes to plant them in beds in the greenhouse or in the garden frame about mid-May. The temperature inside a well managed small frame within another, will be about seven degrees higher than that of the house or big frame. Of course, where a frame is placed on a hot-bed, there will not be any difficulty as regards temperature. The most care, here, must be given to the regulation of the atmospheric moisture and the guarding against rank gases arising from the hot-bed. Always use water that has been placed in the structure several days beforehand, and make up the bed a week before the young cucumbers are planted out finally.—CHRISTCHURCH.

Mulching and Mulching Materials for Vegetables.

AT this early date it may, to some cultivators, seem quite unnecessary to trouble about mulching crops. But it is not too early, to give some attention to the matter. Later, when the soil is being dried up rapidly, there is haste to get material to cover it with and, often it happens that there is not any suitable available. Owing to the recent wet weather the grass on our lawns has grown rapidly and it requires frequent cutting with scythe or mowing machine. In every case all cut grass should be stored in a dry place in a thin layer and not in a pointed or conical-shaped heap, which would cause it to heat unduly, burn and turn yellow. The short grass forms an ideal material for mulching, but it cannot all be obtained in a single week. Begin to store it now and a good heap will be available just when required. Dry straw, old hay, well beaten to get rid of the seeds, will also prove useful if thrown into a heap and turned over several times during the month of May. It may be too dry now, but later on, after the treatment suggested, it will be in good condition as a mulch material and valuable, too, as a manure. Old potting soil should be stored in a dry place, sifted at leisure to remove the crocks and any coarse, dead roots in it. In due time the mixture will prove very beneficial to such crops as dwarf beans, lettuce, dwarf growing peas and runner beans. Care should be taken in collecting material for mulching purposes that matured weeds, bearing seed pods, are not gathered up at the same time, as the seeds would soon germinate and cover the ground with weeds. Burn all such weeds and coarse material, returning the ashes to the soil. Usually, the work of mulching is put off too late and then the crops are not benefited by such applications.—HANTS.

Club Root in Greens.

THERE are several forms of club root, the one caused by a fungus and another caused by the larva of a weevil. As many thousands of plants will be planted out in every district throughout the country during the immediate future, every care should be taken to render the soil sweet and suitable. Liming purifies the soil, but lime is best applied during the autumn months. Where this was not possible, the cultivator should not hesitate to apply lime now, in dust form for preference. The soil is dug in the usual way and then about one peck of dust-like lime should be applied to each square rod of ground. Scatter it evenly on the surface, then lightly rake it in while the soil is fairly dry. It is when the roots are diseased or in a bad state owing to impurities in the soil that larvæ of the weevil attack them and not while they are perfectly healthy. If lime is not available, apply agricultural salt at the same rate—one peck per rod. Failing these, use a similar quantity of soot, but not soot *and* lime together. An initial precaution is that of rejecting all young plants already showing signs of club root; it would be more economical to leave the soil fallow for a time and then sow turnips.—G. G.

GREENHOUSE NOTES

Hardening Off Plants for Bedding.

THE time is near at hand when it will be needful to make arrangements and take certain steps for the hardening off of plants which for the last few months have been reared and grown under glass so that they may be fitted for planting out of doors in the near future. For this purpose a cold frame is essential. The present occupants of frames, such as pentstemons, calceolarias and violas, can now have the lights removed altogether during the day at least, and at night be tilted to admit air. The weather is the predominating factor just now which must decide when the sashes can be removed altogether.

Indoor plants in pans and boxes which are deemed to be sufficiently advanced for a cooler temperature must also come under review, such things as larkspurs, tagetes, lobelia, asters, stocks, antirrhinums, petunias, salpiglossis, zinnias, as well as young plants in pots of fuchsias, heliotropes, pelargoniums—to name some of the most popular bedding subjects. At present most greenhouses are filled to their utmost capacity, and room is badly needed for other things which may still have to be pricked out for later blooming. There is, in such circumstances, always a temptation to transfer tender plants to frames before some of them are actually large enough. This is a mistaken policy sometimes, and is often fraught with danger unless care is taken to cover the frames with mats or bags at night for some weeks. To proceed cautiously is always the wisest, using discrimination as to what shall and shall not go into frames first. Taking things which are very tender, such as zinnias, Phlox Drummondi, French marigolds and salpiglossis, it is more prudent to keep these in the coolest part of the greenhouse as long in May as possible, rather than consign them to a greatly reduced temperature. As we know, May is a month of extremes of temperature, hot sun in the day often being succeeded by frosty nights. It is therefore well to be cautious, and not to be too anxious in getting plants into frames, unless one can close them early in an afternoon and cover them at sunset.

Ventilation.

A hard and fast rule cannot be laid down in regard to the ventilation of frames at this time of the year. On cold, sunless days it is safer to afford but little, and then the lights ought not to be opened very long. It is easier to starve young seedlings than to endeavour to undo the damage through their being exposed to cold currents of air. Watering should only be done early in the day, and then only sufficient given to keep them going. It is better to keep plants on the dry side in the absence of sun. One cannot always work to a given date in getting plants into their summer quarters out of doors. It will often be found more profitable to keep small plants in a cold frame a week or two longer than is customary rather than hasten their removal outside when weather conditions are not suitable.—CLAREMONT.

Primula sinensis.

THE Chinese primula is one of the most useful plants for the decoration of the greenhouse and conservatory during the winter and early spring. The present is a suitable time to make a small sowing, and two further sowings may be made at intervals, to provide for a succession of flowering plants.

Sow in a well drained pot or pan, in a compost consisting of 1 part loam, 1 part leaf-mould and a liberal admixture of sharp sand. Previous to sowing, well water the pot or pan with boiling water from a fine rose can; this sterilises the soil. Sow the seed thinly and cover very lightly with a sprinkling of sand. Place a sheet of glass over the pot, cover with a piece of paper and place in a house having a temperature of 55 degrees Fahr.

No water will be required until the seeds germinate, and immediately this takes place the glass and paper must be removed. When large enough to handle, prick off at a distance of 4ins. apart into boxes filled with the same compost as before, but in a roughe condition. The addition of a little lime rubble will be found advantageous. From these boxes they may be transferred when large enough to their flowering pots. I prefer this method to that of potting them in the very small state, as they are so liable to dry out and get overlooked when in small pots, whereas in boxes they all receive more uniform treatment and this results in more even plants. Take care when pricking off or potting not to bury the crown of the plant; on the other hand, they must not be allowed to wobble about on the surface of the soil. Always water with care, without wetting the foliage or centre of the plants. During the summer a cold frame facing north is a suitable place in which to grow Primula sinensis.—H. E.

Marguerite Carnations for Cut Flowers.

PANS or pots are better than boxes for raising these carnations from seed, as the soil in them remains more consistently moist over a long period. A too light loam should be avoided; good sound loam and well rotted leaf soil in equal proportions will constitute a suitable compost in which to sow the seeds. Provide ample drainage, fill the pan three parts full of the compost, press it down moderately firm, water, then sow the seeds thin. apart, cover them nearly ¼in. deep with a similar compost, but do not water the covering soil. Place glass and paper on the pan and the latter on a stage or shelf in the warm greenhouse or frame. If the plants are to be flowered in pots, transplant the seedlings singly in small pots at the first and, in due time, repot twice, the last time in 6in. pots. The compost for the repottings should be loam and leaf soil in equal proportions where the soil is of a clayey nature; and loam two-thirds and leaf soil one third where the soil is medium to light. A sowing made in May will yield plants that will form a succession and bear blooms through the late autumn and winter-time.

VOL. XCI.—No. 2891. APRIL 30, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

THE *Rose Annual* for 1927 fully lives up to the high standard of its predecessors. As a guide to rose cultivation and to the activities of the National Rose Society, under whose auspices it is published, it is invaluable. There are many interesting articles dealing with various aspects of rose history and culture, and all are full of instruction for the amateur grower. Two are of particular interest, in that they deal with points about which little is known and, consequently, on which information is greatly desired. These are the articles on Roses and Their Parentage, by Mr. H. R. Darlington, the present President of the Society; and the Newer Species of Wild Roses, by Mr. A. Osborn. What we—and, no doubt, many rose lovers also—would like to see in a future *Rose Annual* is an authoritative article on the history and evolution of our present-day roses. Much of the history of the evolution of our modern types is shrouded in mystery, and we feel sure that all rose lovers would be interested to learn of the many Chinese species of wild roses which have been responsible for the creation of the many beautiful types which are to be seen at a modern rose show to-day. The critical articles on last year's shows of the Society make interesting reading and indicate the progress and development of the Society and what it is doing to assist and encourage rose-growing throughout the country. The success of the Society is further evidenced on looking through the Report. Steady progress has been made during the year, and the membership stands at the figure of over 14,000—surely a record for any horticultural society outside the Royal Horticultural Society. It is a figure which has only been reached through much hard work, and we would extend our congratulations to the committee and, above all, to Mr. Courtney Page, the energetic secretary, on bringing the Society into such a successful position.

Nothing succeeds like success, and it is certain that the Society will achieve still greater things in the future. A feature of this year's *Annual* are the coloured illustrations of roses, all of which are well executed. It is a volume which should be in the hands of all rose lovers and one which they will find of extreme service in the culture of their plants.

Exhibition Culture.

NEARLY every town and village in the land has its flower show. At these shows it is not uncommon for the entries to number over a thousand, so that the total number of separate exhibits staged by amateurs must be well over a million each season. Anyone who has judged these shows knows that a great many inferior exhibits are staged, largely because many exhibitors do not make adequate preparation early in the year. The question of seeds and plants is most important in exhibition culture. Get the best varieties, and remember that a new variety is not necessarily the best. The leading seedsmen print the best kinds in heavy type in their catalogues. Go to a good firm for your seeds—one with a reputation to lose. "Penny Pictorials" without name or date, are useless for exhibition work.

The next item of importance is the soil preparation. One of the exhibitors of prize vegetables at amateur shows turns his soil over *four times* each winter before sowing or planting. Thorough digging and soil aeration are essential, and manure, organic and inorganic, must be used to secure the best results.

Photographic Competition Rules.

1. All photographs sent in must be taken by the reader or submitted with the consent of the actual photographer.
2. Prints should be on smooth surface paper and preferably in black tones, and can be of any size. Figures may be included where these are helpful to the composition.
3. Prints need not be mounted and negatives must not be sent.
4. The name and address of the sender must be clearly written on the back of each photograph, together with a few explanatory words, such as the names of the flowers, where grown, when planted or sown, or anything which gives point or lends interest to the picture.
5. Each photograph must be accompanied by a coupon, to be found on page xiv, and a piece of cardboard should be used to prevent damage in the post. Envelopes should be marked "Photographic Competition" on the outside and addressed to The Editor, THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2.
6. A stamped addressed envelope must accompany all photographs. The Editor will endeavour to return those which are considered unsuitable. If this rule is not complied with, prints will not be returned.
7. The Editor will not hold himself responsible for photographs lost or damaged in the post or otherwise.
8. No correspondence can be entered into.
9. All photographs published will become the copyright of THE GARDEN.

To the reader who sends in the photograph which the Editor considers the best of the week a prize of 21s. will be awarded. For all other competition photographs published 5s. will be paid. Payment will be made about the 7th of the month following publication.

This Week's Work

For Gardens in the South and Midlands.

Plant out violas, border carnations, cabbages and cauliflowers.

Apply worm-killer to lawns and weed-killer to paths.

Sow in nursery beds such biennials as hollyhocks, sweet williams, Canterbury bells, mulleins, etc.

Clip and trim evergreen hedges and creepers and finish planting evergreens.

Make further sowings in the open of hardy and half-hardy annuals.

Spray fruit trees with lead arsenate.

Start hardening off bedding plants and prepare beds for summer bedding.

Plant wall climbers and creepers.

This Week's Work

For Gardens in Scotland and the North.

Sow annuals in positions where they are to flower.

Spray rambler roses for green fly.

Take cuttings of wallflowers.

Harden off stocks, asters, etc., preparatory to transplanting.

Complete planting of gladioli.

Plant early London cauliflowers.

Fork in old manure in rose beds.

Put out parsley seedlings raised in boxes.

Continue planting late potatoes.

Dust gooseberry bushes with hellebore powder.

Transplant onions and leeks for exhibition.

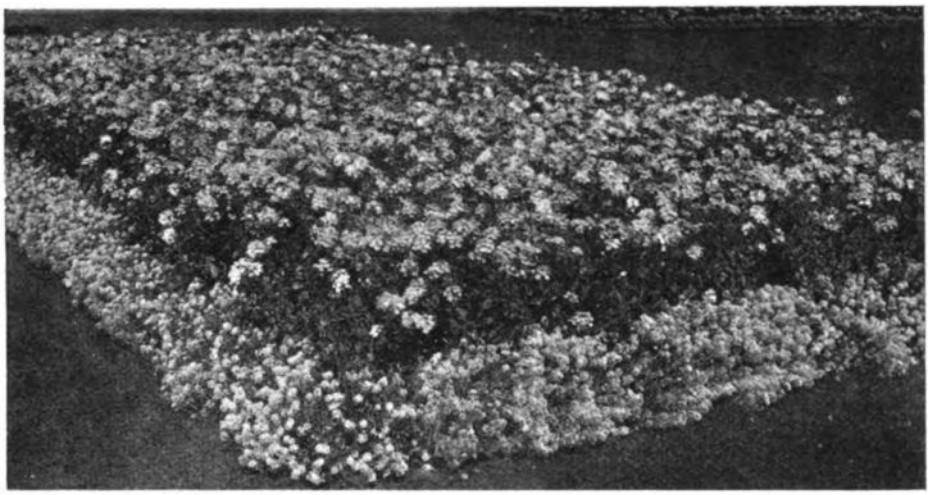
Remove frame lights in daytime.

Digitized by Google

SUGGESTIONS FOR SUMMER BEDDING

A start should be made within the next two or three weeks so that the beds will not be left empty when the spring flowering plants have been lifted.

ALTHOUGH the days are long gone by when beds and borders that were left stark and bare at all other seasons of the year were filled up for the summer with fearful and wonderful devices in yellow calceolarias, blue lobelias, "golden feather" and Mrs. Pollock pelargoniums, a certain amount of "bedding-out" is still necessary in most gardens, especially if a feature is made of spring-flowering bulbs and plants which are taken up in early June.



A FINE BEDDING DISPLAY OF VERBENAS WITH AN EDGING OF ALYSSUM.

PHLOX DRUMMONDII IS A FIRST-RATE BEDDING PLANT FOR A BRIGHT SHOW.

In planning bedding schemes careful attention should be given to the question of background and surroundings. For instance, if the flowers in the beds will be seen against dark-foliaged shrubs or a grey stone wall, a warm and vivid combination in which orange, scarlet or bright full rose is the predominating colour may be advisedly chosen, but if the background happens to be the raw red brick of a brand new house, low tones of colour should be selected, and all shades of red and pink avoided. Then, again, if the aspect is excessively hot and sunny and there is no shade from trees, shrubs or neighbouring buildings, a cool effect rather rather than a gay one should be aimed at. A big bed of scarlet geraniums, salvias or begonias, beautiful as these flowers are in themselves, is not exactly restful to the eye when seen under a blazing sun on a hot August afternoon, especially if it happens to be surrounded by a path of yellow gravel, glittering white spar or marble chips! For such a situation a scheme in which cool lavenders and blues, soft pinks and oyster white or creamy yellow prevail, with, perhaps, the addition of a grey foliaged plant such as Cineraria acanthifolia or the little silvery Cerastium Biebersteinii, will be found much more satisfactory. It is, however, far easier to find suitable plants for sunny situations than shady ones; indeed, there are very few desirable summer "bedders" that will thrive in anything more than very slight shade. Petunias, fuchsias, Calceolaria mexicana and the "marguerites" (Chrysanthemum frutescens alba), once so popular but now comparatively seldom seen, with violas, Omphalodes verna and Limnanthes Douglasii (rather too early flowering, however) for edgings, are, perhaps, the best plants to choose for beds that get but a limited amount of sunshine.

Another point to be remembered is that little beds in a little garden call for treatment other than that required by big ones in a spacious setting. For small beds only plants of neat habit should be selected. Such imposing things as cannas and dahlias are best eschewed, and "dot" plants, if wanted at all, should be only slightly taller than those of the "filling." In most cases the happiest effect is arrived at by choosing a plant that can be obtained in several colours, or shades of colour, and using it alone. Antirrhinums (intermediate and dwarf), Phlox Drummondii, Dianthus Heddewigii, nemesias and balsams, with Candytuft Little Prince or Lilac Queen, Alyssum Snow Carpet or Eschscholtzia Miniature Primrose for edgings, are all specially suitable for little beds.

It is, perhaps, almost superfluous to say that all beds, whether large or small, should be considerably higher at the centre than at the edges, the sloping up being very carefully graduated.

A Few Schemes for Summer Beds.

1. Salvia Pride of Zurich or Fireball; edging and carpeting, Alyssum maritimum Little Dorrit; centre, miniature dahlia Cheal's White.

2. Pink intermediate Antirrhinum Dainty Queen; edging, Ageratum Little Blue Cloud; centre and dot plants, Gladiolus primulinus Maiden's Blush.

3. Dwarf rose and white godetia; edging, pale mauve Viola Maggie Mott; centre and dot plants, tall godetia Sutton's Double Rose.

4. White ten-week stocks: edging, Nasturtium King of Tom Thumbs; centre and dot plants, Lobelia cardinalis Gloire de St. Anne. (Alternative for centre, scarlet Tropæolum Lobbianum or bamboos.)

5. Clarkia Rose Beauty; edging, Nemophila insignis, centre and dot plants, Gladiolus primulinus Ada (white, flushed pink).

6. Mixed double French marigolds (dwarf); edging Dimorphotheca aurantiaca or Nasturtium Ladybird; centre and dot plants tall double orange African marigolds.

7. As No. 6, but with Cineraria acanthifolia as dot plant and Cerastium Biebersteinii as edging.

8. Mixed single Aster sinensis (mauve, pink and white); edging Verbena Sutton's Pink or Viscaria Tom Thumb Rosy Gem; centre and dot plants, tall Antirrhinum Rosy Queen.

9. Clarkia Purple Prince; edging, dwarf Eschscholtzia Primrose; centre, camellia-flowered Dahlia Dobbie's Bedder (pale gold).

10. Zinnia Queen of Roses; edging and carpeting, Candytuft Little Prince; centre, Barr's Giant Antirrhinum Snowflake or Gladiolus White Giant.

11. Mixed salpiglossis; edging, alternate plants of Violas Purple Queen and Golden Sovereign; centre, standard heliotrope.

12. Double asters (dwarf chrysanthemum-flowered) rose-pink and white; edging, Silene pendula dwarf rose or pink Saponaria calibrica; centre dot plants, Sutton's Mammoth Rose aster or Lavatera rosea Loveliness.

13. Tall mixed petunias (striped); edging, dwarf white petunias; centre, rose-purple and white fuchsia, or pink and white double cosmos or Antirrhinum Purple King. R. E. H.

DESIGNING THE SIDE GARDEN

A few helpful points concerning the lay-out of the piece of ground that extends along the sides of the house.

IT is often difficult to decide upon the best treatment of the pieces of ground that lie on both sides of a house that is centred upon the frontage of a plot of ground. In some cases there is a strip of garden ground some twenty feet or more wide that, beginning at the fence, runs along the side of the house to the back, where it either joins the rear garden system or ends at a barrier formed by trellis or a hedge. Of course, nowadays the garage will solve the problem on one of the sides; but when the frontage extends for 80ft. or more, there is a wide gap between the house and boundary fence that has to be decoratively filled.

One way of doing this suggests itself at once, and it has been much adopted in the past, and that is to fill in the space with shrubs. Too often has this been done, with the effect of creating a dark, forbidding thicket; and this, with perhaps trees and shrubs in the front of the house, have made an environment that is deadly dull, restricted and monotonous. Let me suggest something more pleasing.

First of all, shrubs are very useful when there is a slope upwards from the road frontage—in some cases shrubs are the only possible solution; but let them be, in the main, flowering shrubs in order to secure brightness of colour, and shrubs with variegated foliage are equally effective. Again, a slope suggests the possibility of a rockery, which is a very artistic feature. The rockery could occupy a site midway between a belt of shrubs and a strip of lawn—some pretty effects can be secured in this way.

I would like more particularly, however, to make some suggestions for the treatment of a strip of ground at the side of a house that is quite level. The most effectual treatment that could be applied to such a piece of ground is contained in the employment of grass and flower beds, the use of a few low shrubs around the wall of the house with the addition of an ornament in stone here and there or quaintly cut trees. Roses are excellent subjects for the purpose of floral decoration, both in the form of standards or dwarf bushes in beds.

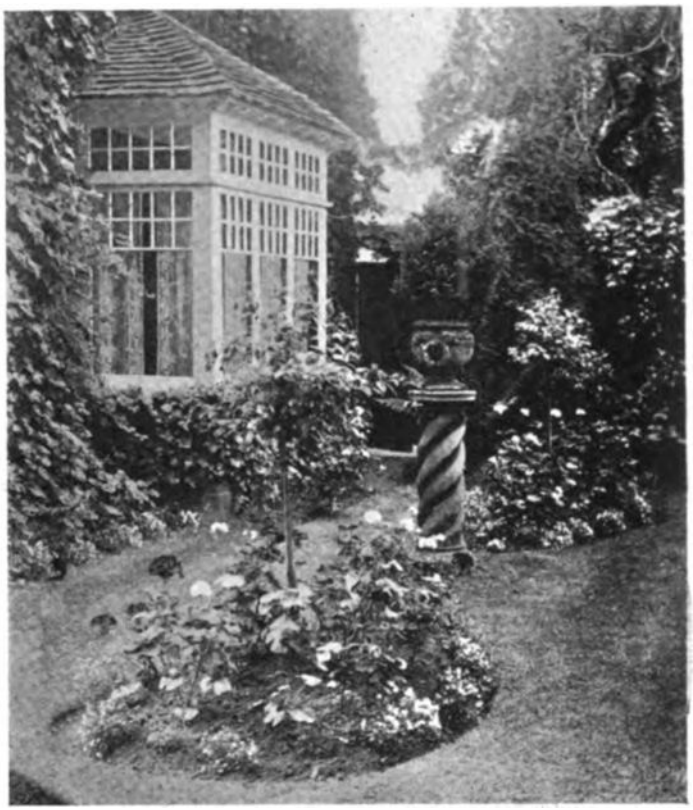
The flower beds should be of the annual order rather than the perennial, for perennials are invariably untidy plants, and, unless the site is a large one, are not at all suitable for the purpose in view. Small beds of any shape should be cut out of grass, and these, with a a small border on either side, along fence and house, would provide garden space for the accommodation of bedding plants, roses, etc., which would produce a blaze of colour all the summer, contrasting so pleasantly with the deep green of well kept grass—a really artistic treatment that would greatly add to the appearance of the frontage as a whole.

Charming aspects can be imparted to a side garden by means of a long strip of lawn edged by narrow flower borders on each side, and an additional decorative feature would be afforded were the edges cut in vandyked or scalloped designs. There is plenty of room and scope for geometrical designs in garden beds and borders by the side of the dwelling-house, and even the drive that leads to the garage may be beautified by the establishment of a border of flowers on one or both sides of it.

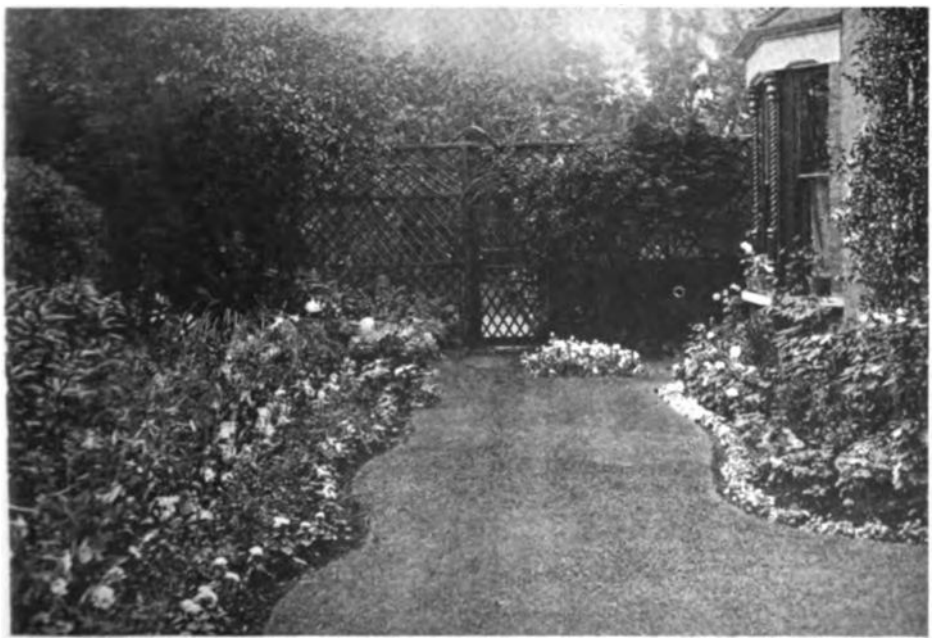
It will be conceded that the artistic appearance of many a house frontage is entirely spoilt by an indifferently planned side garden. Modern tendency is towards an open space all round the house, so that the home environment shall be airy and bright, and the opportunity is afforded, in the absence of a mass of trees and shrubs, to lay out the spare piece of ground at the side of the dwelling to artistic advantage. As one walks past a house, a swift glance takes in its frontage, and in that glance must be included the side gardens, for curiosity prompts it. Some people are content to block up their side piece of ground by a barrier of trellis and shrubs, as if they have no actual use for it, whereas they might make the ground a decorative asset.

There is another side to the question. What shall be done in the case of a side garden that gets but little light or is draughty, as often happens? It is true that one cannot expect to create a garden of colourful flowers and brilliant foliage effects in the absence of sun. Yet there are possibilities of decorative treatment. Grass will always grow, and the stone or leaden statue is not dependent upon sunlight for its beauty; these things may be employed to save the inartistic situation. Ferns suggest themselves as a help to rockery treatment, seeing that shade is essential to their well being. A fernery is a first-class solution of the problem of a dull aspect, and the building of a rockery, in conjunction with the laying down of crazy-pavement or flagstones, would create a most artistic wing to a house.

The plan of combining rockwork with paving is best achieved without the introduction of grass. If ferns are planted on the rockery, the spores will find their way to the joins in the pavement, and little ferns will spring up; or such could be planted for immediate effect, as well as the thymes, mossy saxifrages and sedums, and soon a most interesting and quaint environment to the house will be the result. N. E.



A PLEASANT FRONT GARDEN WITH BEDS OF SUMMER FLOWERS, STANDARD FUCHSIAS AND PELARGONIUMS.



A BROAD GRASS PATH EDGED WITH WIDE FLOWER BORDERS GREATLY ADDS TO THE APPEARANCE OF THE HOUSE SURROUND.

PRUNING EVERGREEN SHRUBS AND HEDGES

The end of April is the best time to trim and train all evergreen shrubs whether newly planted or well established.

THE shortening and thinning of the shoots of evergreen shrubs is in some respects different from that of deciduous shrubs. It is not possible to frame several rules, as can be done in the case of deciduous shrubs, to improve the quality and increase the quantity of blossom.

The pruning of evergreen shrubs is not desirable when cleaning through the shrubbery borders in winter. The best time to prune and thin the branches of most evergreens is in spring, about the end of April in most cases—earlier in the south and west—when new growth is about to recommence. Should April or May be the flowering season, as with Berberis stenophylla, for example, defer cutting until the flowers are past. The usual reasons for pruning evergreen shrubs are to maintain shapely bushes, to prevent them becoming too large for their positions and thus perhaps crowd their neighbours.

When shrubs become too large for their positions or tall and bare at the base, it becomes necessary to cut back the branches into oldish wood. Many evergreens respond quite as well to this treatment as do deciduous shrubs. If the hard pruning is done in spring, just before growth recommences, the cut branches may look ugly for a week or two, but new shoots will soon furnish the stumps. The severe cutting, in the case of flowering shrubs may mean the loss of a season's blossoms but it allows a long season of growth and a more rapid recovery. Take care to dress the cuts with tar to prevent decay of the wood and attack by fungi. Popular shrubs that can be so treated include rhododendrons, laurels, phillyreas, Olearia Haastii and Veronica Traversii.

During April or early in May specimen hollies, yews, evergreen oaks, etc., which are kept formal in outline, should be gone over with secateurs, removing growths which tend to destroy the more or less formal character desired. It will be necessary to repeat this operation during the summer, when dealing with specimens which are kept closely cut and very formal, quite an Eton crop, in fact. Shears are more often employed for the latter.

Pruning Newly Planted Evergreens.

It is found very helpful to the bushes in practice to prune evergreen shrubs when transplanting. This, because of the disturbance and loss of roots, as it were, balances matters. The shortening to two-thirds or even to one-half the length of the branches may not be too much when there is very little soil attached to the roots. Do not be concerned if some of the leaves wither and fall from

THE CLIPPING OF SPECIMEN EVERGREEN SHRUBS, SUCH AS HOLLIES, CAN BE CARRIED OUT IN SHOWERY WEATHER.

the branches of evergreen shrubs. In fact, it is worth while assisting nature when the supply of plant food is interrupted by removing half the leaves.

The hard clipping of ivy on buildings and fences is best done in April when new growths soon refurnish the bare appearance.

Pruning and Clipping Hedges.

The hard pruning of evergreen hedges is best done in spring when new growth is recommencing. In dealing with old yew and holly hedges it may be desirable to prune the top one year and the sides the following season. Cultivation of the ground must also play its part in the rejuvenating of old hedges. Clean the surface soil around the plants, give a top-dressing of rich turfy loam and very old decayed manure, or bone meal.

When only one annual pruning is practised this should be done when the year's growth is practically completed, say the beginning of August, which allows time for the newly cut appearance of the shoots to disappear before winter. The cutting of closely clipped yew, privet, quick and similar hedges will begin in June and be repeated twice or three times at about monthly intervals.

Prune Now, Unless Stated Otherwise.

Aucuba japonica.—The Japanese spotted laurel may have old branches cut out to the ground, shorten loose and unevenly disposed shoots.

Berberis.—If required, shorten long growths of Darwin's barberry after flowering. Clip hedges of B. stenophylla, and shorten long branches of bushes.

Cotoneaster.—Long branches of C. buxifolia may be considerably shortened if required and C. thymifolia have the loose ends of branches removed to obtain compact pleasing growth.

Escallonias.—Hard cutting back into old stems, or shorten and thin branches after flowering.

Ilex Aquifolium varieties.—Shorten loose uneven branches of hollies, cut back to older stems when growing too big.

Lonicera nitida.—Cut back loose twigs of this evergreen honeysuckle, especially when transplanting.

Mahonia Aquifolium.—The Oregon grape can be very freely pruned annually after flowering and thrives in shade.

Pyracanthas.—This is the time to hard prune the fire-thorns, though it means the loss of a season's fruits.

Veronica speciosa varieties.—Thin and prune to form shapely bushes and neat hedges. V. Traversii, when tall and leggy, can be cut down to within 2ft. of the base.

Viburnum Tinus.—The laurustinus benefits by the shortening of long branches to make compact bushes and hedges; should be closely trimmed now with secateurs.

A. O.

A SMALL HEDGE WITH SPECIMEN HOLLIES IN A SUBURBAN GARDEN.

These can be clipped and cut back now to promote a neat and tidy appearance throughout the summer months.

A YOUNG HEDGE OF YEW WHICH SHOULD BE HARD PRUNED NOW WHEN NEW GROWTH IS COMMENCING.

The leaders should be cut back 6ins. to 9ins. and the side branches trimmed sufficiently to form close and even growth from the base upwards.

MULLEINS TO SOW OR PLANT NOW

These stately perennials, with their handsome spikes of yellow blossoms, are first-rate subjects for border planting. Many are best treated as biennials, and seed should be sown during the next two or three weeks.

AN unaccountably neglected group of plants is the mullein family, which includes some of our stateliest summer perennials. It is hard to account for the fact that this family is so seldom represented in the modern garden. Perhaps it is that most people think of verbascums as tall, ungainly plants that at the best should be relegated to the wild garden. It is true that some members of the family do grow rather large, but they are very beautiful in their right setting, and, as the following notes will show, there are many quite dwarf species that are at home in the smallest garden.

All the species may be raised from seed sown outdoors during spring and early summer, the seedlings being moved to their flowering quarters in the autumn. The hybrid sorts, however, should be bought as plants from advertisers in this journal, for they cannot be relied upon to come true from seed.

The best soil in which to plant mulleins is that of a light, well drained nature, and the sunniest spot possible should be chosen. In heavy, waterlogged soils they are apt to behave as biennials, and so must be raised from seed annually.

Mulleins are ideal plants for the herbaceous border, the taller sorts being planted at the back, of course. In the wild garden or on dry, sunny banks or slopes they are quite at home, and make a bright show during the summer months.

The genus verbascum is noted for the vast number of flowers that are crowded on the individual spike, and almost all the following will throw up spikes of soft coloured flowers throughout the whole summer.

V. olympicum (Olympic mullein) is one of the most stately of the group, with huge pyramids of golden yellow flowers and beautiful silvery leaves. It is a true biennial species, and must be raised from seed annually. Height 6ft.

V. Chaixii is a dwarfer plant, but, nevertheless, equally pleasing. The flowers are borne on a many-branched spike, and are of a pleasing shade of yellow, with a conspicuous central whorl of purple filaments. There is a white form which is very pretty, and this is listed under the name of V. C. album. Both grow to a height of 5ft. or so, and are perennial in well drained soils.

V. phlomoides is another giant species, growing 6–7ft. high, and having woolly foliage and fine spikes of bright yellow flowers.

V. densiflorum produces long spikes of coppery yellow flowers, but the spikes do not branch enough to make this species really showy in the border. The wild garden seems to be this plant's true home, and there it is really handsome with tall coppery spikes towering up to a height of 6ft. or 7ft.

V. nigrum (dark mullein) is a native plant, but not to be despised on that account. The tightly packed spikes of yellow blossom are freely produced, and make a good show in the summer border. V. n. album is a good white variety, and many people prefer it to the yellow form. Height 3–4ft.

V. longifolium (syn. pannosum) is a very handsome species with silvery foliage and branching spikes of bright yellow blossoms. This is one of the giants of the family, and will easily reach a height of 8ft. in congenial surroundings.

When we come to V. phœniceum all previous ideas of the mullein family are upset. Instead of a giant 6ft. or more in height, we have a dainty little plant rarely exceeding a height of 2½ft. Instead of the usual shades of yellow, we find that phœniceum strikes out into pleasing shades of rose, purple, red, white and lavender, while in habit it is very bushy and free branching. The purple mullein, as it is called, is very showy in the border, and whatever else is omitted, should be one of the first to be tried.

VERBASCUM PHLOMOIDES, WHICH REACHES A HEIGHT OF SOME 6 TO 7 FEET, IS A FINE PLANT FOR A NARROW SHADY BORDER AGAINST THE HOUSE WALL.

THE DAINTY VERBASCUM PHŒNICEUM OF NEAT BUSHY HABIT AND ONLY ABOUT TWO FEET HIGH IS ADMIRABLE FOR PLANTING IN A BED OR BORDER. *Here it is seen to great advantage in a bed with forget-me-nots as an edging.*

Lastly, we come to the beautiful hybrid verbascums that have recently been evolved. Of these Miss Willmott is one of the best, with tall spikes of white flowers and soft woolly grey foliage. Caledonia is another good variety, with spikes of sulphur yellow flowers suffused with bronze. Height 4ft. Harkness' Hybrid is of a bright yellow shade, and grows about 3ft. high; while cupreus is a pretty blend of copper and purple, and also reaches a height of 3ft.

There are many other verbascums besides these, but the cream of the collection will be found among those enumerated above. May I plead for a wider cultivation of these lovely plants? I am sure they will please all who care to try them in the garden.

THE BUSY MAN'S PAGE

Disbudding Roses.

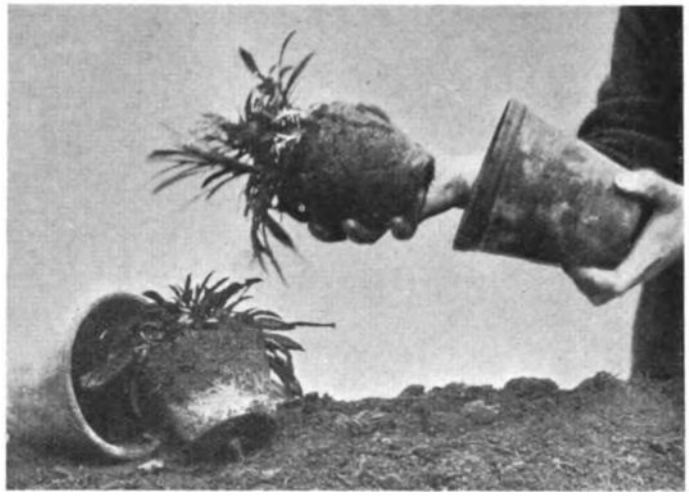
EXPERT rose-growers with exhibitions in mind are quite aware of the necessity for disbudding, both as regards the buds and the young shoots. Those who are growing roses simply for garden and house decoration would be well advised to give these matters a little consideration. Examine almost any rose bush during May and it will be seen that certain shoots are growing towards the centres. These threaten to cross each other and become crowded, and some of them will be growing out in a very awkward manner. Nothing but good results can come from the removal of some of the weakest of these shoots, although care must be taken to maintain the shape of the bush as a whole. It should be borne in mind that these small shoots will, if allowed to remain, be branches by the end of the autumn.

At Bedding-Out Time.

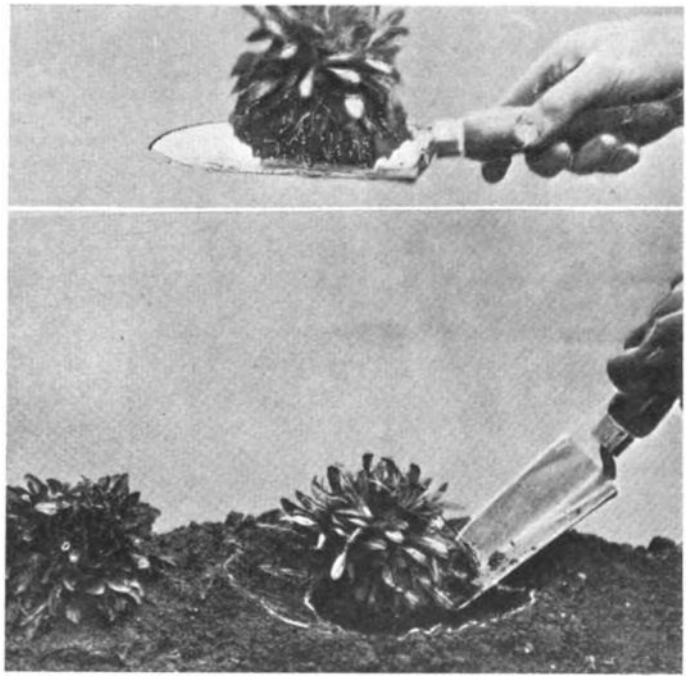
SUCCESSFUL bedding-out always depends on the way the plants are put into the ground. If the planting is done badly, a check is given to growth from which the plants do not recover until the best of the growing season has passed, and the result is a late show of blossom usually cut short by cold autumn weather. To avoid this let there be as little disturbance as possible at planting-out time. Make the hole large enough—too large, in fact—and with a trowel or small fork. If the plants are in pots, remove them without in any way breaking the matted soil and roots which all well grown plants will possess. Placing the fingers around the neck of the plant, turn the pot upside down and give the rim a sharp rap upon the edge of a wooden bench or block, and the contents will slide out unbroken. Transplanted from the ground or from boxes, the plants should be lifted with a trowel, and as large a ball of earth and roots as possible should be taken up and conveyed straight to the hole made ready for it. The least possible disturbance is then caused to the roots and a good start ensured.

How to Grow Fine Bushy Wallflowers.

WALLFLOWERS, being quite hardy, should be treated as such from the seedling stage. When not so treated, they often fail to give satisfaction. Two common mistakes are made by inexperienced cultivators: the first, sowing the seeds in boxes under glass; the second and the most common, sowing the seeds too late in the year. The seed should be sown in an open bed not later than the month of May. A point will be gained by sowing them at the end of April in a well prepared outside border. A rich border is not advocated, but one deeply dug and firmed while the soil is fairly dry. An ordinary kitchen garden soil will do admirably, and if some builders' old mortar rubble is added to it the seed bed will be an ideal one. Make shallow, flat drills; sow the seeds very thinly and cover them lightly. Before the resultant seedlings become overcrowded, transplant them at 4ins. apart in a nursery bed similarly prepared. In a very short time many will form side shoots; others, that do not form such shoots, must be stopped to cause these necessary side shoots to grow. By early October the plants will have covered the ground and be good bushy specimens, 90 per cent. possessing from five to nine branches. By March the following spring the plants will have entirely covered the soil in their permanent quarters and bear a profusion of flowers, mostly even in height. There is a vast difference between such specimens and those left overcrowded in their seed beds or those weakened by coddling. One plant grown as here advised is better than four of the last-named.



REMOVING BEDDING PLANTS FROM POTS WITH THE BALL OF ROOTS AND SOIL INTACT.



LIFTING A PLANT WITH A TROWEL AND PLACING IT IN A HOLE LARGE ENOUGH TO ACCOMMODATE THE ROOTS.

Wallflowers require a long period of steady growth.

When the Crops will be Ready.

THE following table is useful when it is wished to know how soon after sowing or planting a crop will be ready for gathering

Beans, broad	13 to 14 weeks
Beans, French	11 to 12 weeks
Beans, runner	12 weeks
Beet, turnip	12 to 14 weeks
Beet, long	18 to 20 weeks
Broccoli	5 to 9 months
Brussels sprouts	6 to 8 months
Cabbage	16 to 18 weeks
Carrot	18 to 24 weeks
Cauliflowers	15 to 18 weeks
Celery	5 to 6 months
Endive	10 to 12 weeks
Kale or borecole	7 to 9 months
Leeks	6 to 8 months
Lettuce	9 to 10 weeks
Onions	16 to 18 weeks
Parsnips	18 to 20 weeks
Peas	13 to 15 weeks
Potatoes, early	14 to 15 weeks
Potatoes, main crop	18 to 20 weeks
Radishes	4 to 5 weeks
Savoys	6 months
Shallots	15 to 16 weeks
Spinach	10 to 14 weeks
Turnips	8 to 9 weeks
Vegetable marrows	15 to 18 weeks

Garden Edgings: What to Plant Now.

THE edgings along the beds and borders play a most important part in the appearance of the garden. An ill kept, straggling edging will spoil the whole garden; a neat, close edging will increase its beauty to an almost incredible extent.

Now is the time to plant these edgings, to be ready for the summer months when the garden is at its best. There is no need to dig deeply or to lay down a lot of manure, but the ground should be well forked and a little cow manure, mortar rubble, bone meal and rotted leaves mixed with the soil.

Nowadays there is a wide choice of garden edgings. Pansies, violas and pinks (double and single) are among the favourite perennials; Virginia stock is an excellent annual edging; which at the same time is cheap and easy to grow. With the latter, all that is to be done is to sow a thin line of seed down the border with a light covering of sifted sand.

Good roots of pansies and violas should be purchased as early as possible and planted at intervals of 4ins. The plants rapidly spread until the gaps are filled up and a continuous edging is formed. Every autumn the plants should be trimmed and all loose growth cut away, leaving the new shoots in the centre to bloom in the next season.

Pinks are also easy to grow. The roots should be lifted and divided every second year; the most promising plants should be replanted and the weak stock thrown away. The chief advantage of pinks for a border edging is the neat appearance of their spiky green leaves throughout the year, both before and after flowering.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Plants for Hanging Baskets.

THERE is, perhaps, no more effective plant for growing in hanging baskets than the Campanula isophylla. The trailing growths can be allowed to hang down unhampered, and its charming blue or white flowers (according to the variety) are produced in great abundance. It is comparatively easy to plant and cultivate flowers in hanging baskets successfully, for they may be hung where they will get the maximum amount of sunshine and water can be given as required. When planting, some care must be taken to encase the soil in sacking or moss, so that it does not get washed away from the roots. The best way to water is to immerse the basket completely under water—tepid rain water is, of course, the best—leaving it until the bubbles cease to rise. Then allow it to drain for a short time before again placing it in position. This treatment will be required at least once a week in the warm, dry weather.

Another plant which might be more widely used in hanging baskets indoors is the rat's tail cactus (Cereus flagelliformis). It needs light and air and a fair amount of heat, and should therefore only be grown in a sunny window or similar position. For a permanent outdoor position periwinkle and hardy ferns could be used.

Other suitable basket plants for summer display are Fuchsia procumbens, F. Golden Treasure, Campanula Loreyi, Asparagus Sprengeri, ivy-leaved geraniums, Lobelia tenuior (bright cobalt-blue flowers with a white centre), Lysimachia Nummularia, Saxifraga sarmentosa (mother of millions) and Nepeta Glechoma variegata.

A basket in which half-hardy plants are used will, of course, need protection from frosts. Where a greenhouse is available this is simple, or the basket, when planted, could be stood on an inverted pot in a cold frame.

A Beautiful Flower for a Town Garden.

ONE of the loveliest flowers for summer decoration is the sweetly scented Datura suaveolens, listed in some catalogues as brugmansia. Knightii is the double white variety. This plant has a woody stem and attains a height under very favourable conditions of 10ft. to 15ft. The leaves are elliptical and shiny above. The flowers are borne in August and are white and pendulous like candelabra. They are famous for their fragrance and their graceful habit.

Although strictly speaking a greenhouse shrub, the plant can be planted outside in the summer, particularly in sheltered gardens, such as are usual behind town houses. As a specimen tub plant there is nothing more suitable for the cool conservatory. The plants come to us from Peru, a country which has given us a wealth of greenhouse subjects. Naturally, being of fleshy growth, the plant requires rich feeding, especially when the flowers begin to show. It can be kept in a cool greenhouse during the winter, but it should be *almost completely dried off*. After starting into growth, the stems are cut severely back, just as one does with a fuchsia, to produce young shoots on which the flowers are borne.

DATURA SUAVEOLENS FLOURISHING IN A SMALL COOL GREENHOUSE.

Culture of Water Lilies in Tubs.

THE cultivation of water lilies in small town gardens is becoming increasingly popular. Among the new Marliacea hybrids, there are several beautifully coloured varieties which are quite easy to cultivate successfully. A depth of water of 9ins. to 18ins. or more is required for water lilies, according to the variety. If you have no pond, it is possible to make one by the simple process of sinking a tub into the ground, and many fine blooms have been secured in such a simple "lily pool." Most water lilies like a rich soil, and a simple and easy method of planting them is to use a wicker basket. Use a compost consisting of two parts rich loam, and one part decayed manure. In this the roots should be made very firm, and the crowns should just show above the surface of the soil. The basket can then be sunk in the water, allowing about 9ins. to 18ins. of water above the plant, according to its size.

Pygmæa alba is the smallest flowered variety, and this is very charming, producing masses of snow white flowers. It can be grown in quite a small tub. Marliacea albida is a very large plant, with a delicious perfume, and white flowers. The variety carnea is also fragrant, with flesh coloured flowers.

When new plants of water lilies are purchased, they should be immediately placed in water when they arrive and covered with a cloth to keep the sun from injuring the foliage.

If the plants come from a nursery near to hand and there has been little delay between the purchase and delivery, it is sufficient to lay a damp cloth over them for a short time until they are planted.

It should be remembered that all water lilies like plenty of sunshine, and if given the full sun will repay with an enormous wealth of blossoms.

A few goldfish in the lily pool are desirable, as they help to keep the water pure and also devour the larvæ of the mosquito.

NYMPHÆA MARLIACEA ALBIDA, A BEAUTIFUL WHITE WATER LILY FOR GROWING IN TUBS

The Town Gardening Handbook.—This volume, the official handbook of the London Gardens Guild, is now published, and is obtainable from all booksellers and newsagents. The price is, cloth covers, 2s. 6d., paper covers, 1s. 6d. It is the one book for all amateurs who garden in town and suburb.

Digitized by Google

NOTES ON THE FLOWER GARDEN

Items for Present Attention.

FROM now onward many items requiring immediate attention will have to be dealt with, and can be performed to time with a little judicious planning. The following are among those which come under this heading: Lawns should be well swept and rolled and mowed weekly, after which the edges around the beds and borders may be trimmed. Fork through herbaceous borders lightly, cleaning off any weeds. Beds planted with spring-flowering subjects should, where possible, have the hand cultivator drawn carefully between them. The pruning of all roses should be finished at once, renewing the ties on pillars and ramblers where necessary—they will need it later on. Thin out growths of perennial phloxes where these are overcrowded, retaining the strongest growths only. Complete planting gladioli; and put out border carnations on well prepared ground, if not already done. Holly hedges may be clipped now, and ivy growing on walls may safely be cut back now. Wet days will be well spent in pricking off the various seedlings that are to provide display during the summer months.

Stakes of various heights to be used for support in the herbaceous borders should be pointed and tied in bundles, if this was overlooked during the winter months; also bunches of twigs for supporting sweet peas in their early stages. Make further sowings of any annuals that have failed. There is still time for these to make good any defects that may have occurred from this cause. Labels may also be written in readiness for sowing half-hardy annuals in the borders. These small details count for much when fine weather prevails and outside work can be proceeded with.—W. F. F.

STATELY HOLLYHOCKS IN THE SUMMER BORDER.

Hollyhocks as Biennials.

Seed Can be Sown Now.

AMONG the stateliest and showiest of our garden plants, hollyhocks are not the least important, their height, coupled with their freedom of flowering commanding attention. It is sometimes puzzling to anyone unacquainted with their rapid growth that comparatively small plants, put into their quarters in spring, should by August have thrown up a flowering spike anything from 6ft. to 8ft. Unfortunately, these handsome flowering plants are liable to attack by a fungus, which, commonly known as "rust" disease, plays havoc very speedily with the foliage and eventually destroys the plants, more particularly those which have occupied the same ground for a couple of years or more. This disease has led many growers of hollyhocks to treat them as biennials, sowing one spring for blooming in the summer of the following year. To do this, one is able to steer clear in a large measure from the fungus, as it gives one the opportunity of planting out in a fresh piece of prepared ground. I use the word "prepared" advisedly, inasmuch as there is scarcely any plant in the garden to which the term "gross feeder" can be more fitly applied. One has only to leave a plant to itself for two seasons, and after that to dig it up, to find that the roots have so permeated the soil as to rob it of every atom of nutriment. Besides this, plants which remain in the ground develop suckers. In the circumstances, it is not surprising that many who cultivate hollyhocks have come to the conclusion that it is much better to prevent disease than attempt to find a remedy for it; and the best possible way is to sow seed every year for blooming the next.

Preparation of Ground.—This is of paramount importance, and should be done thoroughly, trenching or deeply digging it, working in what rotted manure is possible. Should the soil be naturally very heavy, it is advisable to lighten it a little by incorporating sand or grit along with vegetable refuse or leaf-mould, leaving it rough for the winter if it is not intended to plant out before spring. Seed may be sown in boxes of light soil in a cold frame in May or June—or in a warm border in the absence of a frame—transplanted, or potted and left in the frame for the winter; but this latter is only essential in very exposed localities where it is scarcely worth risking planting out seedlings in late autumn.

Final Position.—Select a place for hollyhocks where the sun reaches them, and a tall stout stake for each is a necessity. In June, old manure as a mulch spread over the surface will greatly help them, and should the weather prove dry copious waterings and occasional supplies of liquid manure will do much towards building up the superb spikes of bloom that are an attraction to any garden.—W. L.

Violet Cultivation.

IT is usually thought that the pure air they require makes violet growing impossible anywhere near a large town. If, however, reasonable care were taken in the selection of a site for the bed, and they were given plenty of attention, they could be grown with success in many suburban gardens.

The safest varieties to start with are the single blue and white and the double Parma. If winter blooms are wanted, the best time for planting is April, and the preparation of the bed should be carried out at once. The best position for a bed is on the north-east side of a fence or hedge, but not in the shelter of a high wall or house; although the plants need partial shade during summer, they will not thrive in the dense shadow cast by masonry.

Any good garden soil will suit violets, but deep digging and careful preparation is essential. Heavy soil may be improved by the addition of road grit and leaf-mould, but rank manure should not be used, as it will cause the plants to "run to leaves." Very light soil is improved by burying old cow dung fairly deeply when preparing the bed, as this helps to keep it moist during summer.

When the young plants are received they should be planted out at once, at least 8ins. apart. If planting is done during dry weather, they should be puddled in, as it is important that they should become established as soon as possible. It is also advantageous to protect them at first with inverted flower-pots during the heat of the day.

The ground round the plants should be forked up frequently to prevent the formation of a crust, and they should be watered freely and regularly, not sprinkled, but given a good soaking.

All runners should be removed, as if they are left the older plants will soon become worn out and cease flowering.

If the position is sufficiently sheltered, winter flowers may be produced in the open, but to make certain it is as well in early autumn to transfer the plants to cold frames, where the crowns should be as near the glass as possible. They should be watered freely and have plenty of ventilation until it becomes necessary to take precautions against frost. Under these conditions flowers should appear early in November, and the period of flowering should be of considerable length.

Blue Alkanet.

Plant Out Now.

THE lovely blue alkanet (Anchusa) will at times suffer severely in the winter, especially where the soil is wet and cold. The propagation of these plants is such a simple matter that there is no reason why anyone should be without them. Often plants of blue alkanet are not so completely dead as they may appear to be and there is still some life in the fleshy roots. By means of root cuttings it is easy to secure large numbers of strong young plants in a short while. All that has to be done is to cut the fleshy roots into pieces a couple of inches or so in length and place them in pots of sandy

Digitized by Google

soil in a frame. Keep the end nearest the crown of each piece of root (the part where the buds are) upwards and only just cover with soil. Avoid excessive dampness, and if the soil is moist at the start no additional water will be needed until the roots start to grow. They may be planted out in the borders at the end of April or in early May. The two best varieties of A. italica are the Dropmore and Opal.

Decorative Plants for a Sunny Border.

LIBERTIAS possess a charm of their own; from tufts of iris-like leaves, there appear in summer panicles of white flowers, persistent and decidedly decorative. They enjoy a warm border and a light, gritty soil and are propagated by seeds or by careful division of the roots in spring; frequent disturbance is undesirable and moreover, large established "pieces" possess a greater decorative value than do smaller plants. Bulbous subjects planted with libertias are very happily placed provided they are not crowded by their more ample neighbours; for instance, a warm border furnished with libertias, thinly planted and interspersed with tigridias, cypellas, etc., would be very charming, the iris-like foliage proving an admirable foil to the brilliantly coloured blossoms of the bulbs. The species usually met with are L. formosa from Chile, with white waxy flowers, and the somewhat larger growing L. ixioides, from New Zealand, with whitish blossoms, a coarser plant than the aforementioned species; grand flora, paniculata and pulchella are others not so frequently grown.—R. A.

LIBERTIA FORMOSA, WITH ITS TUFTS OF DARK GREEN IRIS-LIKE LEAVES AND SHEAVES OF HANDSOME FLOWER SPIKES.

The African Lily for Growing in Tubs.

FOR more than two centuries the African lily (Agapanthus umbellatus) has been grown in British gardens. The plant is not only handsome with its glorious blue flowers, but it is also extremely easy to manage. It is only needful to keep it free from frost during the winter, and many growers store their plants in a shed or a cellar during the cold weather. In warm, sheltered gardens of the south and west, the agapanthus does quite well in the open border, and here, in course of time, it will develop into a huge plant. Probably the plant would succeed in this way in many localities, especially if it was protected with dry litter or bracken during severe weather. Mostly the African lily is grown in large pots or tubs. It thrives best in ordinary potting soil, such as loam, leaf-mould, old decayed manure and coarse sand. Repotting may be carried out in the spring, but this is seldom desirable, as plants which have not been moved for some years flower best. Increase is easy by division of the roots, and propagation by seed is also possible.

With the return of fine, warm weather, it is most important that the agapanthus should have abundance of water. Frequent applications of liquid manure will also prove very helpful. During the winter resting period of the plant very little water is needed. Tubs or pots of agapanthus are very handsome when stood in prominent positions, such as by the side of a path or near the house door. In a sunny position the flowering season is prolonged over a considerable period.

There are six or eight varieties of the African lily. On the whole, most imposing is the type with its many-flowered umbels borne on stalks 2ft. to 3ft. high; the white variety alba has pure white flowers; maximus is of very vigorous growth with rather larger leaves; minor is a miniature African lily, needing only a 5in. or 6in. pot and growing to the height of about a foot—this plant flowers very freely; variegatus, a pretty sort with white green-striped leaves; and flore pleno has double blue flowers.

AFRICAN LILIES PLANTED IN TUBS ARE USEFUL FOR DECORATION IF GIVEN A POSITION ON THE ENTRANCE PATH TO THE HOUSE.

Plant Periwinkles to Cover Old Tree Stumps.

THE treatment of a tree stump often presents difficulties, especially if this, as sometimes happens, is in rather a shaded position. In such a position there is no plant so useful as the periwinkle (vinca) in one or other of its forms. Practically all these grow with rapidity in any soil or situation. The best plan is to set strong roots round about the base of the stump and then allow the shoots to trail over the wood. The common periwinkle (V. major) is of very vigorous growth indeed, and there are some fine forms with variegated foliage. The lesser periwinkle (V. minor) is a much smaller plant, but this also grows with great freedom and is more prone to ramble. There are several varieties well worthy of cultivation; a white-flowered one (V. m. alba), a reddish one, and some double forms, in addition to several kinds with variegated foliage. Two other species of periwinkle are to be recommended. The first, V. herbacea, is a native of Hungary, and is a very attractive plant with pale blue flowers; V. acutiflora, from southern Europe, has a habit of producing its delicate mauve blooms in the late autumn and winter, and is worth growing on this account alone. It should be noted that the last species must be given a sunny and somewhat sheltered position, as it is rather more tender than the other garden periwinkles.

ENEMIES OF THE ROSE

Immediate remedial measures must be undertaken at this season whenever disease becomes apparent on your roses. Prevention is always better than cure, and timely and systematic spraying with approved washes will add greatly to the appearance and flowering qualities of the bushes.

TO the admirer of our national flower, the rose, it will come as a rude awakening to learn that there are over forty species of insects and at least a dozen fungus diseases which attack this popular plant. But he need not be unduly alarmed, for he can cope with nearly all the troubles by keeping a critical eye on his plants and spraying with the necessary materials as soon as the pest or disease is observed. Roses in most parts of the country are troubled with two pests—green fly (aphides) and caterpillars; and two fungus diseases—mildew and black spot.

Errors in Cultivation.

Excessive mulching with farmyard manures, and heavy dressings of nitrogenous artificial manures are to be avoided, for both these treatments induce sappy growth and delicate foliage, thereby laying them open to attack by aphides and mildew. Lack of potash in the soil accounts for increased susceptibility to fungus diseases, and this may be remedied by successive applications of wood ashes or kainit.

Badly drained soils and heavy waterings of light soils are to be guarded against, for the vitality of the plants is lowered, rendering them liable to attack by various fungi. Roses are lovers of fresh air and sunshine, but they are often grown in small enclosed gardens in which a static atmosphere is the rule rather than the exception, with the result that under such conditions mildew is rife. Failure to attend to the requirements of plants in the way of a plentiful supply of fresh air and sunshine is to court disaster. It is a fallacy, long exploded, that roses need a heavy clay soil, for they will flourish on light soils provided that they are supplied with the necessary nutrients.

Preventive Measures.

As wild roses act as hosts for nearly all the pests and diseases to which the cultivated plants are heir, attention should be paid to hedgerows in proximity to rose gardens and the wild plants treated against the troubles to which they have succumbed. All prunings should be burnt in order to destroy the eggs of various insects (*e.g.*, aphides and moths), the boring grubs of many sawflies and the resting stage of several pathogenic organisms. Fallen leaves are a constant source of trouble in carrying over many fungus diseases, especially black spot, and all leaves should be raked up in the autumn and burnt.

A SHOOT OF A ROSE BUSH AFFECTED BY MILDEW.

Remedial Measures.

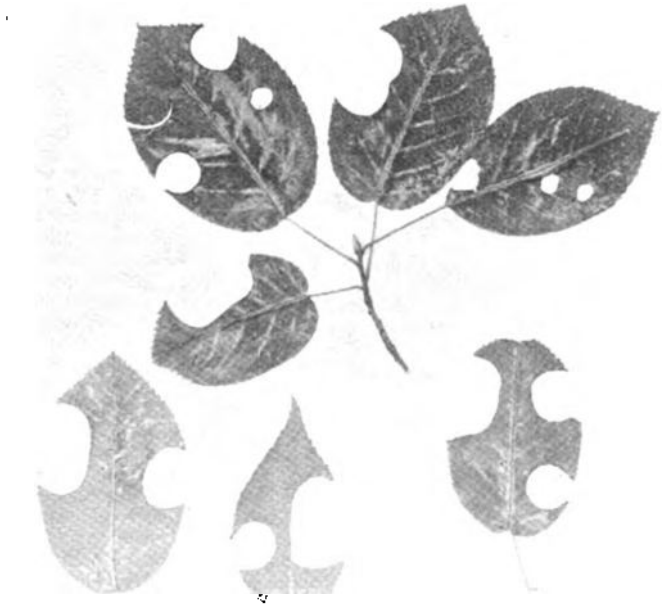
A great amount of useful work can be done by handpicking the caterpillars of moths and false caterpillars of sawflies, and destroying them in hot water or in water in which a little oil has been placed.

When spraying is resorted to, it is essential that an efficient machine be used, for disappointing results will follow the use of an inferior one. For use in small gardens it will be found that either a continuous-spraying syringe or a pneumatic (compressed air) sprayer will give satisfaction. The type of nozzle is another important factor in efficient spraying, and two kinds are necessary, *viz.*, a fairly coarse jet for use with contact washes against aphides, leaf-hoppers, cuckoo-spit and scale insects, and a fine nozzle which gives a mist-like spray for use with lead arsenate wash and fungicides.

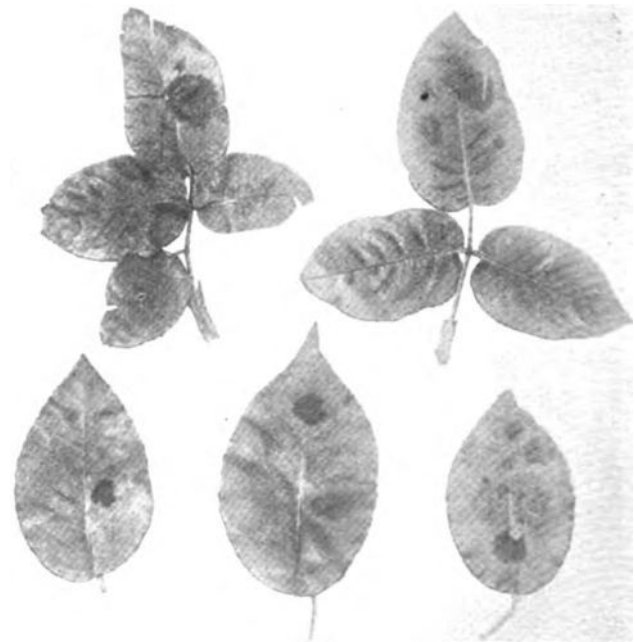
When spraying against sucking insects, a thorough drenching should be given to all parts of the plants, paying particular attention to the under surfaces of the leaves and the young growths. On the other hand, when lead arsenate wash or a fungicide is used, it is equally essential to coat both surfaces of the leaves thoroughly, but drenching must be avoided in order to eliminate waste by the wash running off the foliage on to the soil.

One application of any wash is usually insufficient to ensure control; this applies especially to lead arsenate wash and fungicides when they are used prior to unsettled weather. Never apply a spray fluid during hot, sunny weather, otherwise scorched foliage will result, and do not choose a cold day but rather wait until a dull, mild day or apply in the evening when the power of the sun is reduced.

Spray fluids should be obtained in a form ready for immediate use and always diluted with soft water. Useful insecticides against



ROSE LEAVES ATTACKED BY THE LEAF-CUTTING BEE.



THE BLACK SPOT FUNGUS ON ROSE LEAVES.

Digitized by Google

(1) sucking insects are nicotine and soap, quassia and soap, and paraffin emulsion, and (2) biting insects are freshly ground hellebore powder and lead arsenate. Copper and sulphur in some form or other are the constituents of most fungicides, the best being Bordeaux and Burgundy mixtures, ammoniacal copper carbonate, liver of sulphur (potassium sulphide) and sulphur (flowers or green).

A useful combined dust can be made by mixing ninety parts of sulphur with ten parts of lead arsenate powder, and will be found most efficient against leaf-eating caterpillars, sawfly grubs, weevils and mildew.

To facilitate the identification of the troubles to which the rose is heir, we will consider them in tabular form. G. F. W.

INSECT PESTS AND FUNGUS DISEASES OF ROSES.

A.—INSECT PESTS.

Pest.	*Symptoms of Attack.*	*Remedial Measures.*	*Remarks.*
Green fly (aphides) ..	Yellowing of foliage, sometimes accompanied by curling; young shoots wilting and clustered with aphides; sticky exudations on lower leaves.	Frequent sprayings with nicotine soap wash or quassia soap.	Spray at first sign of pest to prevent destroying their natural enemies, *e.g.*, ladybird grubs, hover fly grubs, etc.
Leaf-hoppers	Yellow, mottled foliage; premature leaf fall.	Paraffin emulsion in June directing wash on to under surface of foliage and on ground around attacked plants.	
Cuckoo-spit	Spittle or froth-like exudation on stems and shoots.	Frequent forceful sprayings with nicotine soap wash.	
Scale insects	Scale-like growths on stems and shoots.	Forceful applications of nicotine soap wash in spring. Rub off old scales in winter with brush dipped in methylated spirit.	
Thrips, red spider ..	Mottled foliage; flowers discoloured.	Frequent syringings with clear water; use nicotine soap in bad attacks.	Choose a dull day for the treatment of the flowers.
Gall "fly"	Moss-like growths on leaves and stems.	Cut off and burn galls in August.	Bush roses susceptible. Cut off galls on hedgerow plants.
Moth caterpillars, false caterpillars of sawflies, leaf weevils.	Foliage and flowers eaten entirely or skeletonised; young shoots devoured.	Handpicking. Lead arsenate wash soon after buds open out and again later.	Watch for egg masses of lackey and vapourer moths in winter and cut off and burn.
Leaf-cutting bee ..	Circular and oval areas cut out of leaves	If bees can be traced back to nest, it should be destroyed at night when the makers are at home.	
Leaf-rolling sawfly ..	Leaves rolled and folded over.	Handpick the rolled leaves and burn. Early sprayings with paraffin emulsion will act as a repellent to egg-laying. Removal of top 4ins. of soil round bushes in December, replace with fresh soil.	Susceptible varieties: Tea Rambler, Captain Hayward, Baroness Rothschild.
Boring sawflies ..	Shoots dying through tunnelling of larvæ.	Cut off and burn affected shoots.	
Tortrix moths, caterpillars.	Leaves spun together and devoured; flowers and buds eaten into.	Early applications of nicotine soap wash to kill young larvæ before they spin.	
Chafers: garden, rose and cockchafer.	Foliage and petals devoured by adults; larvæ of two last-mentioned feed on roots with result that plants wilt and appear unhealthy.	Handpicking or jarring chafers on to greased boards on dull days; handpicking larvæ and forking in naphthalene round plants just before rain.	Flowers of climbing varieties preferred.
Weevils, raspberry, etc.	Buds, foliage and young shoots devoured.	See under chafers. Trap adults in May and June under pieces of sacking placed round attacked plants. These insects are nocturnal feeders and hide away in daytime.	

B.—FUNGUS DISEASES.

Mildew	Whitish spots on young foliage, later spreading over entire leaf, causing distortion and leaf fall; patches later turn brown.	Frequent dustings with green sulphur or spray with liver of sulphur and soap, Bordeaux mixture. Burn prunings.	Susceptible varieties are Mrs. John Laing, Mme. Gabriel Luizet, Mrs. R. G. Sharman Crawford, Joseph Lamy, Philadelphia Rambler.
Black spot	Black and purplish spots on upper surface of foliage leaf fall in bad attacks.	Early applications of Bordeaux mixture or ammoniacal copper carbonate. Pick up and destroy fallen leaves; burn prunings.	Susceptible varieties, Juliet, Una, Grüss an Teplitz.
Rust	Rusty patches on foliage which later become dark.	Pick up and burn diseased leaves; cut out and burn diseased wood; spray as soon as buds burst with liver of sulphur and soap.	Common on wild plants in hedgerows.
Leaf scorch	Scorched-like patches on foliage; premature leaf fall.	Pick up and burn fallen leaves; spray as soon as buds burst with liver of sulphur and soap.	
Chlorosis	Leaves become yellow and shrivel; premature leaf fall; stems sickly.	Spray plants with iron sulphate, 1 oz. dissolved in 6 galls. water; lightly fork in 1 oz. iron sulphate crystals round each plant in early spring.	Prevalent on calcareous soils.

MOWING AND MOWING MACHINES

THE beneficial effect that close and regular mowing has on turf is simply extraordinary, and the truth of this is very apparent to the observant. If grasses are allowed to grow to maturity and seed the plants are actually exhausted, many die, and the growth of the rest for the remainder of the year is negligible, unless the season happens to be warm and wet.

If, on the other hand, it is regularly mown short, the strength of the plant is thrown back to the roots, which form a dense mat and throw up a multitude of fresh green blades in place of a few, relatively speaking. Such continue to grow as long as moisture and temperature permit, and so form what we know as turf.

When grass is not cut, the tall varieties submerge those of a dwarfer character; but if it is closely mown, exactly the opposite happens and the dwarf grasses expand, crowd and starve their more robust relatives.

The change in the condition of turf from coarse to fine has led to much controversy, and it has actually been stated that the variety and nature of grasses can be changed by close mowing. This is only half true; the variety of grasses cannot be changed by mowing, but their habit of growth can.

Some broad-leaved grasses can be forced by partial exhaustion to produce finer herbage by constant mowing, others die out, and the finer varieties become more prominent.

The average lawn that is abandoned during the winter assumes a coarse, dingy, ragged appearance, which is not wholly eliminated until it has been mown several times in the spring. This clearly proves the importance of close mowing all the year round if a fine, close, durable turf is required.

Roller Machines with a 12in. to 16in. Cut. Until quite recently, mowing machines had developed to a pitch which became practically fixed, and little or no improvement was made in them. A new machine, however, was put on the market by the J.P. Super Lawnmower Company, which embodies many novel and valuable features. The machines are made in two sizes, 12in. and 16in., their mechanism is both dust and dirt proof and runs in oil, with the consequent reduction in friction. Ball-bearings are fixed to the back axle and rotary cutting cylinders, which makes them easy to push; while the adjustment for setting the cutter and the roller bearing front rollers is effected by two hand wheels, which simplify matters and eliminate spanners.

Then Ransomes brought out their "Marquis" with a 12in. and 14in. cut, which is claimed to be the only machine on the market fitted with ball bearings at every journal.

Other excellent machines are Ransomes' "Automaton," Shanks' "Caledonia" and Green's "Silens Messor." All these are offered with gear and chain drive in many different widths of cut. The gear-driven type requires fewer adjustments than those driven by chains, but the latter type is easier to push and gives the better results.

Side Wheel Machines, 13in. to 19in. Cut. These are very easy to push, but, unfortunately, they do not give the pleasant "light and shade" effect of the roller machine, and can only be recommended by those who want to get over the work as quickly as possible without regard to the finished effect.

GREEN'S "SILENS MESSOR" LAWN MOWER.
An efficient hand-power machine.

Many people own good and efficient machines of well known makes, and, although desirous of cutting out hand labour, hesitate to scrap their machines and purchase a motor mower.

This class is adequately catered for by what are known as motor pushers. These are self-contained power units, which can be attached to any make of lawn mower of the roller type with a cut of from 16ins. to 27ins. I have personally operated the "Rendle Motor Pusher," both with a mowing machine and a heavy roller, and it did its work splendidly. Ransomes also make one which carries the operator as well as pushing the mowing machine. The running costs of these machines are very small, as they consume only about one pennyworth of oil and petrol for each 1,000 sq. yds. mown, or about 5d. an acre.

The motor proper developed slowly from a makeshift combination of a lawn mower fitted with a petrol engine, to self-contained, complete and efficient units, designed from start to finish by experienced motor engineers. The motor mower is, without doubt, the machine of the future, and those who have any doubts in regard to its reliability, efficiency and economy should, if possible, make a trial of one of the numerous makes.

Many gardeners are, perhaps, a little conservative, being content with the old hand machines; but after working for one day with a motor machine they will be converted by its success, as it undoubtedly cuts out half the mowing hours and three-quarters of the labour.

There is no doubt that hand and horse machines are doomed, for the simple reasons that they are uneconomical in time and labour and not as efficient as the power machines. The secret of good mowing lies in the excellence of the bottom blade, the diameter of the cutting cylinder, the number of knives fitted, and the speed at which it revolves. It is obvious that bottom blades of equal merit can be fitted to any class of machine, but the size of the cutting cylinder and the speed at which it revolves are strictly limited in hand-operated machines, because any increase in either calls for extra effort which is not forthcoming. This disability cannot, however, be associated with power machines; it is simply a question of design; and as a power machine does not get tired towards the end of the day, the machine travels along and the cutting cylinder revolves at the designed speeds without variation.

The secret of good turf lies, to a large extent, in close and frequent mowing, and as power machines will cut as closely as they can be set, without extra effort, it is plain that they have an enormous advantage over the hand machines, which are difficult to push if close set, unless, indeed, the grass is cut daily during the growing season.

How to Choose a Machine.

For small areas, where a power machine would, obviously, be uneconomical, there is

RANSOMES' "MARQUIS" LAWN MOWER.
A serviceable machine for general use.

THE J.P. SUPER LAWN MOWER IS LIGHT RUNNING AND HAS ADJUSTABLE CUTTING BLADES.

Digitized by Google

no alternative but to use a hand machine. For large areas, select a power machine with a cut of 16ins. to 42ins., according to acreage and circumstances.

In order to arrive at the most economical machine, let us take a definite area of an acre and find out the distance machines of various widths will have to travel to mow it. With this information, it will then be an easy matter to make the same calculation for any area. As this is purely for the sake of comparison, no allowance is made for turning or overlapping, as both of these depend on the skill of the operator and the shape and lay-out of the ground.

Width of Cut in inches.	*Distance travelled in yards.*
12	14,520
14	12,445
16	10,890
18	9,680
20	8,712
22	7,920
24	7,260
30	5,808
36	4,840
42	4,148

Motor Mowers, 16in. to 22in. Cut.

There is a wide range of such excellent machines that it is a matter of very great difficulty to make a choice and one is usually influenced in the end by some unimportant feature. There is, however, one very important point to bear in mind when buying mowing machines: that it is best to buy from an established firm with a good reputation. Some buyers put price before everything, and they are right in doing so if the price is right; but if they simply buy the cheapest they generally buy trouble. Full particulars of these various makes will be found in our advertisement pages, and the information given there should be studied closely, and further particulars obtained from the respective makers.

A DENNIS MOTOR MOWER IN USE.

This machine is among the best of the heavier type of motor mowers and is suitable for use in large areas.

Motor Mowers, 24in. to 30in. Cut.

Many firms also make this class of machine, but the great break is made by the "Dennis," which is built on the lines of a motor with a specially designed chassis. The 4 h.p. four-stroke engine is easier to start than the usual two-stroke, and the driving rollers are fitted with differential gear in accordance with motor car practice. It has many other strong points, and, like most other powerful engines, can be fitted with a trailer seat.

It is obviously impossible, without taking up an enormous amount of space, to discuss the question of mowing machines closely. Many have been passed over altogether, or with only a few words, that may be excellent machines. In fact, I have only attempted to draw attention to the outstanding features of some of what I consider to be the best.

How to Clean Mowing Machines.

The majority of people are reluctant to bring water into direct contact with mowing machines, and yet they do not hesitate to use them when the grass is heavy with dew or drenched with rain, and put them away covered with wet grass and dirt, which dries and hardens into position.

All mowing machines—hand, horse or motor—should be thoroughly cleaned every day by using a hose or water can and a soft brush. The water will quickly remove all the grass and dirt from the knives, gears and machine generally, without doing any damage at all; the paint and oil will protect the metal. After cleaning, run the machine for a few seconds with the handles depressed and the blades clear of the ground, and so get rid of as much water as possible; then oil and grease where necessary, and it will be clean and ready for use when next required. The motor of a power machine should not be cleaned with water; all that need be done is to wipe it over with a greasy swab.

REGINALD BEALE.

FOR SCOTTISH GARDENS

Seasonable Work in May—Planting and Treatment of Vegetables.

TO the amateur who cultivates his own garden May is a month when there is not the same necessity to observe the "ca' canny" policy which guided his efforts earlier in the season, for the risk of injury to plant life arising from the vagaries of the climate is almost negligible in a normal year. Main crop sowings of vegetables are among the first operations that demand attention, and hardy annuals should also be sown in the beds or borders where they are to flower, and by the third week a start may be made with the interesting work known as the bedding out of summer flowering plants.

When sown in May, turnips has less chance of running to seed than plants that were sown earlier in the season, and in small gardens where there is only room for one crop it is customary to rely on the later sowing which provides the household supply of turnips from the beginning of July onwards.

Beet is usually grown for winter use, and as the plants have a very long period for development it is not advisable to sow earlier than the middle of May. If space has to be considered, it is a good plan to adopt a system of crop rotation by sowing beet at a much later date in ground previously occupied by spring cabbages and first early potatoes. As the plants require to be thinned out to 4ins. or 5ins. apart, the seed should be sown thinly in narrow drills sufficiently wide to enable the hoe to be used freely, and a light dressing of nitrate of soda or sulphate of ammonia at the rate of 2oz. to the square yard applied in the last week of July or early days of August has a beneficial effect on the weight of the roots.

Dwarf beans are occasionally disappointing in small gardens, but the cause lies not so much in the soil ro situation but in wrong methods of culture. As beans of the dwarf French type are very tender and are susceptible to cold winds or late ground frosts, it is not safe to make the first sowing before the end of May, and when allotted a sunny position in the border they seldom fail to produce pods in abundance in late summer and early autumn. A secondary cause of failure is overcrowding. There is a tendency on the part of inexperienced gardeners to sow the seed too thickly and afterwards fail to appreciate the benefits of judicious thinning. Well grown plants require a minimum space of 6ins. between each, while the rows should be at least 18ins. apart. No special preparation of the ground is necessary beyond that provided for leguminous crops, but a sprinkling of nitrate of soda between the rows during growth promotes production and weight. Moisture is essential to success. During dry weather the plants should be soaked twice a week, and when the pods have come into bearing they should be pulled while they are quite young and tender. When allowed to develop the pods become coarse and tough, while the plants go out of bearing more readily.

With the advent of May, cauliflowers that have been hardened off can be planted out of doors in their permanent quarters. Cauliflowers are not cultivated in Scottish gardens as extensively as the other members of the brassica family, because, being more tender, they are not so easily grown, while losses are a common experience in consequence of attack by maggots and other ground pests. Another objection which is sometimes urged against the cauliflower is that the hearts all mature about the same time, and consequently some of them decay before they can be used. Small growers seldom raise their plants from seed, but depend on the nursery trade for their supplies. In this connection a word of advice may not be out of place. Try to obtain autumn-sown plants. Though they may be smaller in size they are hardier and better provided with roots than the spring-sown specimens. The latter are deceptive in their appearance. The large leaves are of a delicate green shade of colour, but as they have been grown in frames and put into the market before they are thoroughly hardened the plants are softer and collapse more readily when transplanted. Cauliflower should be put out in a dull or showery day when the soil is moist, and they should be plentifully supplied with water in dry weather, otherwise they are liable to form heads that are too small for table use. As a protection against the small white maggots which attack the stems and roots place the plants in a puddle composed of water, soil and soot, and place a creosoted disc round each stem so that it will rest on the surface of the ground. These discs are most effective for the purpose and are cheap to purchase. Allow a space of 18ins. between the plants and 24ins. between the rows. Like all other members of the cabbage family, cauliflowers take a great deal of nourishment out of the ground, which should be deeply dug and well manured beforehand. Firm planting means firm growth, and a light dressing of nitrate of soda given three or four weeks later is advantageous to the development and maturity of the plants.

WHAT OUR READERS SAY

CHOICE FLOWERING SHRUBS.

SIR,—To persuade a man to change his politics is a difficult task, but I verily believe such a task fades into insignificance compared with that of persuading an amateur gardener to curtail a certain line of his hobby and develop another. In true British fashion he places his back to the wall and defies all comers to prove that any other phase of gardening is better than his, and it is this attitude I would like to see proved wrong.

The phase of gardening I would like to see made much more popular is the cult of the flowering shrub, particularly the so-called tender or half-hardy sorts, which may be easily grown by thousands of people living around our sea coasts. That these choice subjects are not confined to Cornwall and the Scillies is proved by the fact that they are grown on many parts of the coasts of the British Isles. Mr. T. W. Briscoe, a constant correspondent to this journal, has charge of a wonderful garden at Chepstow, on the Severn; Sir Herbert Maxwell has often described the choice plants growing in his gardens in Scotland; Lady Byng is planting many tender shrubs at her home on the East Coast; while in Ireland a number of gardens exist in which these subjects flourish and prosper.

Why, then, are they not more grown in our coastal districts? The answer was given me by a friend last week who had seen Erica melanthra, Edwardsia tetraptera microphylla and Erica australis in full bloom for the first time in his life. "I couldn't grow them and could not afford them." This from a man who grows about a thousand rose trees for a hobby and whose garden is ideally situated for such shrubs! The cultural treatment presents no difficulty, and 7s. 6d. would purchase the three shrubs and all their beauty, while scores and scores could be raised from seed at less than half this cost. Again, I believe the very beauty of many shrubs leads people to think they are extremely difficult to grow, and I am sure that few could see Acacia Baileyana, with its delicious fragrance and yellow glory, or the leptospermums with their masses of white or pink or deep crimson flowers and copper-coloured leaves, or a wind-break of Metrosideros tomentosa towering towards the heavens and presenting a sheet of scarlet flowers for the world to admire, without desiring the same plants for their own gardens. Yet if only it was realised that the growing of such shrubs is as easy as growing laurels, hydrangeas and even privet, and if only the veil of ignorance that surrounds them was lifted, I am certain they would be added to hundreds of gardens.

Any of the following, to mention only a few, whether grown as a single specimen or in groups, would be a thing of beauty, if not for ever, at least for many, many years, at a minimum amount of expense and labour: Cassia corymbosa, Tricuspidaria lanceolata, Diosma gracilis, D. uniflora, Embothrium coccineum (the Fire Tree), eucryphias, Fremontia californica, leptospermums, some of the olearias and acacias, Gaya (Plagianthus) Lyalli, Prostanthera rotundifolia, callistemon and metrosideros, and Lomatia ferruginea.—P. E. CHAPPELL, *Cornwall.*

WATERPROOFING A CEMENT PATH.

SIR,—I was very interested in your correspondent's letter about making a cement path, but I have always found that cement yields a certain amount of dust when swept, and your readers may like to know of a remedy for this. It is the colourless waterproofing liquid that is used for damp walls—there are many brands on the market, such as "Waterex" and "Szerelmey" liquid. Put on after the cement is dry, it causes a film impervious to water and assists greatly in the preservation of the surface.—B.

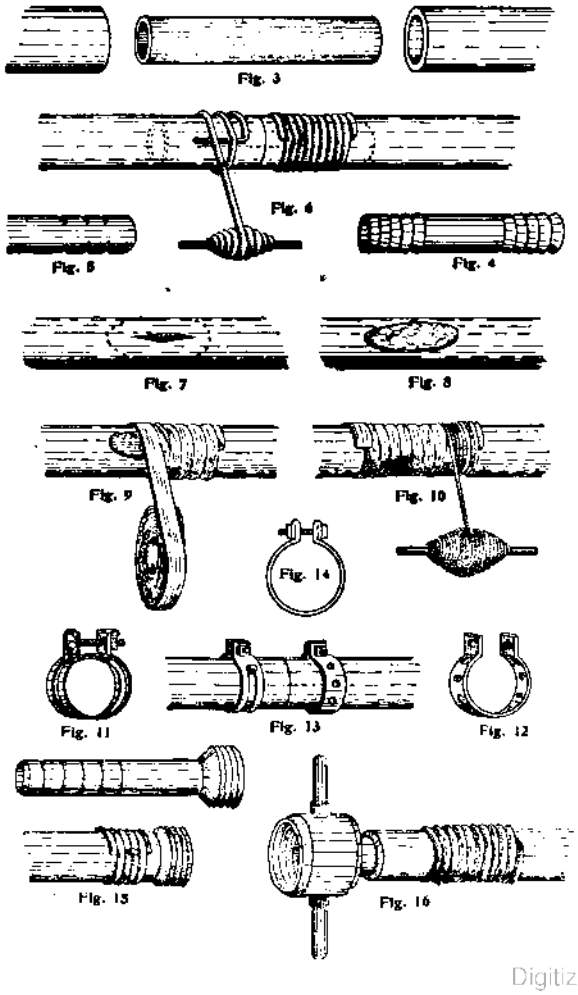
THE CARE AND REPAIR OF GARDEN HOSE

ORDINARY garden hose is made of rubber and is generally strengthened by an internal lining of canvas, either 1-ply, 2-ply or 3-ply, the latter being the strongest and able to withstand a considerable water pressure. It is made in three sizes, ½in., ¾in. and 1in. A much stronger variety of hose in the above sizes and in 2-ply and 3-ply, is bound or armoured with coiled wire. With careful use, garden hose will last for many years, but when not in actual use, it should be coiled up and hung in a cool, dry place, being rubbed with a rag dipped in glycerine to keep it soft and pliable. At the end of the season, all water should be drained out of it and it should be kept free from frost. When again put in use, the next season, it is best placed in a tub of water for a short time. This has a softening action and prevents the rubber from becoming hard and brittle.

Damage to hose is generally caused by allowing it to lie on the ground where it can be trodden on, or by exposing it to extremes of heat and cold. To prevent damage, the hose should be coiled on a reel after use and placed in a convenient position out of the way.

The usual method of attaching a length of hose to the water tap is either by means of a brass union joint which is screwed to a specially made tap, or by the tap union shown at Fig. 1; this union is made to fit the usual sizes in taps and hose. The rubber cone is the only portion liable to wear, but it is easily renewed by unscrewing the top portion, as shown. Another method of attaching hose to a tap is by means of a brass clip, as at Fig. 2, which shows a length of armoured hose attached to the end of an ordinary tap. It is a good plan to fit about 12ins. or so of coiled wire on all lengths of hose at the tap union end, as the tubing is liable to be bent at this point.

When it is necessary to join two lengths of hose, either to lengthen it or to cut out a damaged part, the two ends should be pushed over a length of brass or iron tubing, as shown at Fig. 3. Specially made connections are available to suit the various diameters and are shaped as at Fig. 4, and although these connections are convenient, any kind of tubing, provided it is of suitable diameter, can be used, but the ends should have file cuts, as at Fig. 5. The hose should be secured to the connection with copper wire of 18 gauge, and in order that considerable pressure can be applied when binding, the wire should be wound on a length of round wood, as shown at Fig. 6. Begin binding by folding a short length of the wire at right angles and place this end in line with the hose, next wrap the wire as tightly and as closely as possible and finish off by pulling the end under two strands, a hole being made with a bodkin or a wire nail.

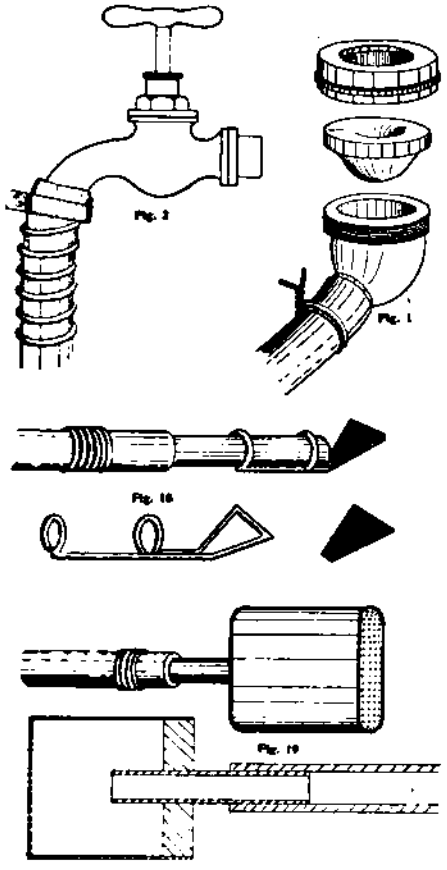


Splits in the hose, provided they are isolated, may be repaired by covering the hole with a rubber patch. The rubber surrounding the break, as at Fig. 7, should be cleaned with fine glasspaper and then coated with rubber solution, apply the same liquid to a rubber patch and when tacky, press in position. The patch should be pressed firmly in position, as at Fig. 8, and then the hose bound with insulating tape, as used by electricians and shown at Fig. 9. The tape may be covered afterwards with string, as at Fig. 10, this will make a perfectly sound job.

Other methods of joining two lengths of hose are shown at Figs. 11 to 16, the first being a brass clip, as shown at Fig. 11. A good clip can be made from Meccano strip, as at Fig. 12, and also at Fig. 13., or with a length of brass strip, about ½in. wide and one-sixteenth thick, as at Fig. 14. The metal screw unions shown at Figs. 15 and 16 are useful for large diameter hose; they should be attached with wire in the ordinary way.

An exceedingly useful hose connection is shown at Fig. 17. It is obtainable at any general merchants. Its advantage over other forms of hose connections is the simplicity with which it can be attached, and, although it only takes a minute or so to fix, the joint between the two lengths is strong enough to stand the considerable strain that garden

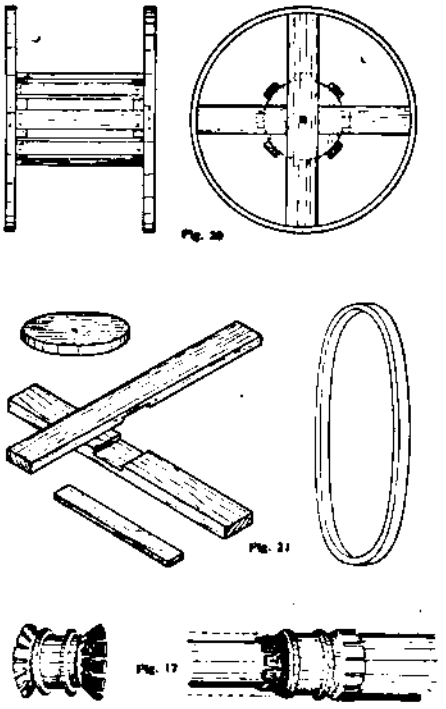
Digitized by Google



hose is subject to and, what is quite important, lengths of hose of different diameters can be joined together with the same fitting. Those who do not wish to make their own fittings cannot do better than obtain these.

There are several kinds of branch pipes, fitted with jet and rose, available, but at times it is convenient to use a spreader, particularly when watering borders. An easily made spreader is shown at Fig. 18 this consists of a length of galvanised or brass wire bent to the shape shown and then soldered. The sprayer may be a plain piece of tinned sheet iron or zinc, but galvanised gauze is particularly effective. If the wire is fairly stout, about 14 gauge, it will be quite strong enough to stand rough wear. Another form of sprayer is easily made and consists of a small tin, as shown at Fig. 19, with perforated end. The bottom of the tin is punched with fine holes, and a ½in. thick piece of wood inserted at the top; the sides of the tin being secured to it with brass screws. The hole for the branch pipe should be a tight fit and when the sprayer is in use the water will cause the wood to swell and prevent any leakage.

Several forms of hose reel are obtainable and, as the use of this appliance is essential to the preservation of the hose, one should either be bought or made. Certain of the metal drums now on the market are excellent and will satisfy every need, but to those who prefer to carry out the work for themselves, the following details may prove useful for making a simple type of wooden drum. A simple form of reel, made of wood, is shown at Fig. 20, and consists of two hoops with a cross framing, to which a drum is attached. The various parts are shown at Fig. 21 and comprise two ordinary wooden hoops about 18ins. diameter, or two hoops from a cheese box; two frames of wood, equal in thickness to the width of the hoops, the same length as the diameter of the hoops and about 3ins. wide. The cross pieces are



joined together by means of a lapped halving joint, as shown, and are shaped to the same curve as the hoops, to which they are nailed or screwed. The drum is made from two pieces of 1in. wood cut to a circle 9ins. diameter and then joined with at least eight lengths of 1in. wood cut to a length of 12ins. and a width of about 1½ins. When complete the reel should be coated with paint or varnished, making it a well finished and attractive job.

SUCCESS IN THE AMATEUR'S GREENHOUSE

Careful ventilation. Judicious watering. Ample space for every plant. These are ideals the amateur cultivator should strive after.

THE amateur's greenhouse is not always the success it might be, and in most instances this is by no means due to lack of zeal on the gardener's part. Often enough the reverse is the case. Gardening under glass is not the same as outdoor gardening, and no doubt hundreds of amateurs fail through what one might call "cooking" their plants. The best plan where there is one small greenhouse is to have it heated just sufficiently to keep out frost or to maintain a temperature of about 45° during hard weather. In such a house it is possible to grow many plants and flowers useful for taking into the house. In summer, tomatoes may be grown, together with tuberous begonias, and such pot plants as will do under the shade of the tomato foliage. A very common fault in such houses is overcrowding. Too many plants are grown, with the result that none succeeds as it should. Another fault is in failing to ventilate the house adequately. Air *must* be admitted on all favourable occasions, but care must be taken to avoid draughts. What is needed is air without a cold draught. Some greenhouses have a very poor system of ventilation—the writer's, when he first began to use it, had very little bottom or side ventilation, and until this was righted nothing would grow really well. The ideal in greenhouse management is an equable temperature. This is obtained by fire heat in cold weather and judicious ventilation in warm weather. The present is a most trying time for the novice, because the sun may shine brightly and yet very keen winds prevail. Experience alone will tell just how to deal with difficulties, but when cold winds prevail we must ventilate first of all on the "leeward" side and be most careful of draughts on the windward side. One thing is certain, then—success depends upon *air*.

Watering of pot plants is a point needing more than ordinary care. The person who waters his greenhouse plants to time-table is asking for trouble (and usually gets it). At the present time watering should be done in the forenoon, where possible, and none done late in the day. There is no rule about watering. Perhaps the best advice is to let a plant become almost dry, then give it a good soaking. Little dribblings lead to trouble.

Among the many suitable plants for the amateur's greenhouse, primulas will always be favourites. In a greenhouse where frost is kept out these plants do very well indeed, and provide a display of colour in winter; in fact, a succession may be kept up by sowing seeds at intervals from now until July. For autumn and winter display seed should be sown now and in succession for later blooms. Primulas are of very easy culture. The seed, which is somewhat erratic in germination, is fine and needs no covering. The plants are best grown as cool as possible—damp is their greatest enemy in the colder months. When the seedlings are ready for potting the cold frame will suit them best, where they may stay, shaded from strong sun, until the end of summer. P. malacoides in all shades of mauve pink, and in white, is a general favourite. P. kewensis is yellow and worth growing. P. obconica is certainly very choice and prolific, the newer varieties being very fine. However, in spite of claims often made to the contrary concerning the newer varieties, this plant affects some sensitive skins, bringing out an uncomfortable rash on many. A little vaseline smeared on the hands before handling the plants is said to ward off ill effects.

Another useful plant for the novice is the cineraria. A great point in growing these plants is to keep them on a cool ash bottom, and shade from strong sunshine. They are apt to be attacked by black fly, but periodical fumigation will keep this pest at bay.

It is quite possible, also, to succeed with azaleas in the amateur's greenhouse, for, although so often forced, these plants really like cool conditions. The best varieties are expensive, but quite suitable plants may be purchased from nurserymen in the autumn. After flowering, the plants are syringed and kept in the greenhouse, later being stood outside in partial shade for the rest of the summer. When flowering, care must be taken to keep the blooms dry.

Success in tomato culture depends on careful ventilation, and watering in early stages. The house must be kept dry. Quite a number of amateurs of my acquaintance grow only tomatoes in summer and chrysanthemums in autumn. However, in such cases it is not wise (where there is only one greenhouse) to try to raise your own seed. The fairly high temperature required by the latter will spoil the chrysanthemums. The only course is to purchase plants (from a good source) ready for final potting.

An article which appeared in THE GARDEN on January 29th, listed half-hardy and hardy annuals for pot culture: these are useful, and plants may be purchased now from advertisers in these pages. In conclusion, may I repeat the rules for success—careful ventilation, judicious watering, space enough for each plant to develop.

T. H. H.

THE KITCHEN GARDEN

Tomato Plants to Fruit Outside.

PLANTS that are grown in the open air throughout the summer are subject, of course, to the weather conditions prevailing. We do not know what kind of weather we shall experience, but we do know that a good beginning is very essential to success, and we can all make that good start because it is possible to buy splendid forward plants from firms advertising in THE GARDEN if we cannot raise them in our own gardens. It is not safe to plant out the tomatoes before the end of May without adequate protection, but it is advisable to look well after the plants in the meantime. Their general treatment in a cold frame now is contained in the following points: To remove, every week, the tiny side shoots growing from the axils of the main leaves and main stems; to attend to ventilation and watering daily. Growing close together, the plants do not require water very often, only sufficient to maintain the soil in an even state of moisture. But they do need ample supplies of fresh air during fine days, and also on dull days if direct cold currents of air can be avoided. This treatment is conducive to sturdiness of plants. Prepare the outside border now.—HANTS.

Thinning Out Seedlings.

UNFORTUNATELY, owing to the recent heavy and very frequent rains, tiny slugs have done much harm in the vegetable garden in some districts. Carrots, radishes, lettuces, especially, have suffered a great deal, and instead of thinning out the crops of carrots more seeds must be sown. Where the soils are naturally light the young seedlings have not been eaten badly. Some growers are afraid to thin their crops at an early stage as they fear blanks; but there should not be any hesitation on this point, especially in the case of carrots, parsnips, beet and turnips. When the surplus seedlings are removed at an early stage, their careful withdrawal does not unduly disturb those seedlings retained, and the carrot fly grub cannot gain establishment easily. The tiny isolated seedlings—by isolated I mean seedlings growing, perhaps, about 1in. away from others that are crowded—along the rows are the ones to retain; but as a rule the seedlings grow more closely together, and then it is necessary to select the one you want to keep, place a finger on the soil close to it and then draw out those not required, and so prevent undue disturbance of the little tap-root. Immediately the rows are thinned use the Dutch hoe between them and also water the retained seedlings with clear water passed through a fine-rosed watering-can. This should be done to settle the soil firmly around the plants, when they will make rapid progress.

The First Crop of Dwarf Beans.

THE first crop of these beans is, sometimes, a failure or a partial one. They may not fail totally, but as a remunerative crop are often most unsatisfactory. Sowing the seeds too early in a cold, retentive soil is the main cause of failure. I have tried early sowing in the open border—early in April—and found that the resultant plants did not make the same satisfactory progress as those resulting from seeds sown late in that month and early in May. If the soil is of a heavy nature, the best plan will be to sow seeds in May; if sandy, light and naturally warm, the first sowing may be made late in April. Dwarf bean plants must grow rapidly if they are to flower freely and bear a heavy crop of succulent pods. Starved, checked plants are of little value. Select the warmest border now in which to sow the seeds. Later on a more open quarter will be advisable, as from midsummer to early in August the very warm border would be conducive to the spread of red spider on the plants. The soil should be rich and deeply dug, and early varieties should be selected for this sowing. Many cultivators sow the seeds in double rows; if ample space be left between the double lines, fine crops may result. But I much favour the sowing of the seeds at 7ins. apart in single rows 18ins. asunder. Each individual plant has ample room to grow in and the pods grow straight all round the upright specimens. If it is convenient, have the rows of plants due north and south. Bury the seeds 2ins. deep.—G. G.

THE SPRING ROSE SHOW

ALTHOUGH the Spring Show of the National Rose Society on April 22nd last was not equal in merit to those of former years, there were sufficient exhibits of good quality to engage the attention of the large attendance. Princess Mary came early in the day and made a prolonged inspection of all the exhibits. To the general garden lover the chief points of interest lay in the large trade exhibits, which contained many splendid blooms. The new rose stand drew the accustomed crowd of enthusiasts, but, apart from the gold medal variety and two new dwarf polyantha varieties, the seedlings did not require prolonged inspection. In several of the trade exhibits the new dwarf polyantha named Golden Salmon, attracted a deal of admiration. It is an especially bright variety that will be an effective plant in the garden.

The large trade groups of cut roses were very beautiful, and Mr. Elisha J. Hicks won the first prize with a handsome arrangement of generous pillars of Lady Reading, Coral Cluster, Paul's Scarlet Climber, Lady Hillingdon, Maréchal Niel and Mme. Butterfly, rising above vases of such H.T. varieties as Charles E. Shea, Souvenir de Claudius Pernet, Angele Pernet, Maman Cochet, America and Mrs. George Norwood. The second prize was won by Messrs. B. R. Cant and Sons, who had vases of Mrs. Beatty, Lady Wakefield, Golden Ophelia, Padre, Mme. Butterfly and other good roses. Mr. George Prince was third.

The groups of pot roses arranged on the floor were particularly effective; while only Messrs. Chaplin Brothers exhibited a circular group of general roses; theirs was an admirable exhibit and contained a great many excellent plants. They had tall standards of American Pillar, Excelsa, White Dorothy and other free-flowering varieties, with shorter, though still tall, standards of Dean Hole, J. G. Glassford, Rev. F. Page-Roberts, Mrs. George Shawyer, Mrs. Henry Bowles and Margaret Horton. The groundwork was composed of generous batches of such dwarf polyantha roses as Golden Salmon, a new variety of delightful bright colouring and great freedom; Susanne Miller, Superba and Ellen Poulsen.

The first prize group of polyantha roses was an excellent arrangement by Mr. J. H. Pemberton. From a profuse groundwork of Juliana, Golden Salmon, Echo and Edith Cavell rose equally well flowered standards of Rudolph Kluis, Greta Kluis and Ellen Poulsen. The second prize group of Messrs. William Cutbush and Son was not quite so well balanced, but the base of Locarno, Golden Salmon, Orleans Rose, Rudolph Kluis and such sorts was admirable. Messrs. F. Cant and Co. were third.

In both sections of the show the exhibition roses were excellent and fully worthy of the best traditions of the National Rose Society. The first prize twenty-four blooms in not fewer than eighteen varieties, staged by Messrs. B. R. Cant and Sons, was a well balanced exhibit.

In his second prize stand Mr. Elisha J. Hicks had good blooms of Mrs. Elisha Hicks, H. V. Machin, Mrs. E. Mawley and White Maman Cochet. Mr. A. T. Goodwin was first in the class for twelve blooms of any one variety, with superb specimens of Maréchal Niel.

Although there were not many baskets of roses, the quality was excellent. Mr. A. T. Goodwin won a first prize with a basket of gorgeous Maréchal Niel, and was also first with the same variety and a fine basket of Frau Karl Druschki. Messrs. Chaplin Brothers won a first prize with a handsome basket of Mme. Butterfly.

AMATEUR SECTION.

While it was not to be expected that they could compete with the trade growers in the size of groups of cut roses, in quality the amateurs fully held their own and the four groups were an important feature of the show. Mr. G. J. Holland, Sutton, was first and he had delightful vases of Dean Hole, Mme. Butterfly, Mrs. C. Lamplough, Caroline Testout and Lord Lambourne in a wholly admirable exhibit. Mr. G. A. Hammond, of Burgess Hill, was a good second.

Mr. E. J. Holland also won chief honour in the section for exhibition roses shown in boxes, and among his twelve were excellent specimens of Louise Crette, Mrs. Campbell Hall, Mrs. C. Lamplough and Dame Edith Helen. Mr. Sydney J. Jackson, Epsom, was a worthy second and his box included an almost perfect specimen of Mrs. Foley Hobbs, the best bloom in the amateurs' classes.

Mr. J. W. Hart won first prizes with six blooms in not fewer than three varieties, and with six beautiful blooms of Mrs. Foley Hobbs. Mr. Sydney J. Jackson was first with six vases of handsome roses in mixed sorts and also with a handsome basket of Marechal Niel, where Mr. E. J. Holland was second with Mrs. Foley Hobbs.

The decorative classes were fully equal in attraction to those at former spring shows. In the open class Mrs. Tisdall, Woodford Green, had the best dinner table decoration, in which she used Roseland a very effectively, while Mrs. L. R. May, Waltham Cross, was second with Mme. Butterfly. These two exhibitors were similarly placed in the class for a bowl of roses.

NEW ROSES.

While a fair number of seedling roses were submitted only one received an award. New varieties that most impressed us were two dwarf polyantha varieties, both shown by Messrs. Chaplin Bros. Susanne Miller is a charming little semi-double pink rose of great freedom in flowering, while Scarlet Leader has larger flowers of the same type and bright scarlet colour. Both varieties would be effective garden roses

GOLD MEDAL

Charles P Kitham.—This showy hybrid tea rose received a certificate of merit at the Society's autumn show last year, when it was seen to rather better advantage in several respects. We suspect that the plants had been forced in a higher temperature than usual in order to have the flowers open for the present show. This would account for the thinness of the foliage and the lack of colour on an occasional petal, which gave the false impression of colour fading. But, nevertheless, it is a handsome rose of orange scarlet tinged with salmon. Shown by Messrs. G. Beckwith and Son.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2892 Saturday, May 7th, 1927 Price TWOPENCE

THE modern dahlia is a flower worthy of being grown in every garden, both large and small throughout the British Isles. With their wide range of gorgeous colourings and their variety in habit, dahlias are admirable for planting both in beds and borders for late summer and autumn decoration. Planting can be carried out from now on until the end of the month.

THE GARDEN

VOL. XCI.—NO. 2892. MAY 7, 1927. PRICE TWOPENCE.

A DAFFODIL CLASSIFICATION

IT is now some time since the first classified list of daffodil varieties appeared, and during the interval, with the large increase in the number of varieties and in the crossing and inter-crossing of the various types, it has become imperative that a new list and classification be prepared and adopted for use at horticultural shows and for general garden purposes. The Council of the Royal Horticultural Society have applied themselves to the task for some time and appointed a committee which, after much deliberation issued a classification of all daffodil varieties, which has undergone much modification from time to time. The present classification which has just been issued by the authority of the R.H.S., embodies the original scheme with the various recent suggestions and modifications incorporated, and, while it seems a useful practical key on the face of it, in practice we have no doubt it will be found wanting. Like all taxonomic keys, it is too general, and in this case all group differences are based on floral characters which are anything but constant. Colour is a doubtful standard by which to judge at any time, even when a hard and fast line can be drawn between individual colours; but when there becomes a merging of the colours, then the standard becomes valueless. In the Classification just produced there are eleven divisions; on a critical examination there does not seem to be sufficient criteria for so much splitting. On the exhibition stand it would be difficult, according to this Classification, to place one flower, say, in the Leedsii division and another closely related in the Incomparabilis group.

"The Garden" Photographic Competition.

ON page 301 of this week's issue will be found the first photographs published in connection with our Photographic Competition. Readers' photographs will be published every week, and we urge all readers who are interested to send along photographs of their gardens during the summer months. Particulars should accompany all photographs so that the illustrations will prove more helpful to the majority of our readers. The rules governing the Competition will be found on page xii.

The differences are purely superficial. What seems to be required is to get down to some bed-rock standards which are fixed for certain classes and which may be accepted as a type round which other varieties can be grouped. In this way the committee would only be following the method of splitting up a large genus like rhododendron and, instead of working with specific characters, varietal characters would be accepted, provided they were fixed. The question is undoubtedly a difficult one, and, naturally, it has to be borne in mind that any classification is purely arbitrary and merely acts as a mechanical aid to identification.

Nevertheless, the list is an exceedingly useful one, and forms a valuable guide to the placing of the vast number of daffodil varieties in their respective groups. In addition, the raiser's name or that of the introducer is given in each case, which makes the list exceedingly interesting. There are a number of mistakes in the names of the varieties and also a few omissions, but these are unavoidable in a work of this description, and no doubt will be corrected in a future edition. The committee ask for assistance in obtaining correct particulars of all daffodil varieties.

About forty pages at the end are given over to a list of names of varieties either lost to cultivation or surpassed by modern varieties. A few are still in existence, but the majority have been lost. The list makes interesting reading and indicates the enormous amount of work which has been done in the development and improvement of the daffodil. It would be interesting, in view of this list, to work out the evolutionary history of our present-day varieties and, by means of dried specimens, show how improvement has been registered. It is unfortunate that all these varieties have been lost without probably any record or specimens having been retained for herbarium purposes. There is little doubt that the Royal Horticultural Society could do much by the establishment of a herbarium for keeping records of varieties (not species, as in the case of scientific herbaria), to encourage and stimulate development in many of our garden flowers, and point out along what lines improvement could be looked for. It is this lack of co-ordination which causes duplication of results and leads to the production of similar, or almost similar, varieties, especially in the case of a flower like the narcissus.

The list, despite its drawbacks, will be found serviceable, and it is a handbook which all daffodil lovers should possess, as it marks a phase in the evolution of one of our finest garden flowers. It will be found an invaluable guide to all growers and to the amateur who grows for exhibition. It is certainly true that the popularity of the daffodil has never been so high as it is at present. This year we saw the finest Daffodil Show for twenty years and, without doubt, some of the very finest varieties which have been produced, and this continued development makes it all the more imperative that we should have some sort of definite classification on which to judge and standardise results, and, moreover, keep a record of them.

This Week's Work

For Gardens in the South and Midlands.

Sow biennials in nursery beds.

Make sowings of spinach, dwarf French beans, carrots and peas.

Prepare celery trenches and plant out lettuces on the ridges.

Begin to earth up potatoes.

Make further sowings of half-hardy annuals in the open border and thin out all seedlings.

Harden off bedding plants.

Support sweet peas with twiggy sticks.

Stake tall-growing herbaceous perennials.

Spray roses with insecticide to keep down green fly.

This Week's Work

For Gardens in Scotland and the North.

Plant out chrysanthemums.

Lift and divide polyanthuses after flowering.

Sow seeds of biennials in open ground.

Prepare celery trenches.

Earth up early potatoes.

Stake sweet peas soon out of doors.

Lift early tulips as soon as the foliage dies down.

Spray roses to control aphis.

Continue transplanting lettuce, if necessary.

Make sowing of late cropping peas.

Protect Darwin tulips and Spanish iris coming into bloom.

DAHLIAS FOR BEDDING

AFTER the spring display of bulbs, biennials or autumn-sown hardy annuals is over, the question arises as to what may be planted to give an effective show during late summer and autumn in those same beds or borders. Dahlias will be found exceptionally useful for this purpose; they are free flowering, brilliantly coloured, and, as they do not need planting outdoors until the end of May or early June, ample time is allowed to clear and prepare the ground.

All types of dahlias are more or less useful for bedding, but in my opinion two classes stand alone for their all-round usefulness and real value—the dwarf bedders and the charms. Probably these two are responsible, more than any others, for the increasing popularity of the dahlia. They appeal to many who do not find other types sufficiently useful or attractive.

CULTURE.

Provided that they are not planted in an entirely shaded position, dahlias will succeed almost anywhere in suburban or country districts. Certainly they prefer an open sunny situation with a good depth of well enriched soil; but their culture is extremely simple. The beds should be dug deeply and a good dressing of well decayed manure and bone-meal incorporated. If horse or other animal manure is unobtainable, hop manure with bone-meal will be found quite satisfactory. Plants from pots (usually rooted cuttings) or dry pot tubers may be purchased now, but unless one has the convenience of a cool greenhouse or cold frame it is wise to ask for their delivery at the end of May. By that time the fear of night frosts will have passed and it will be safe to plant outdoors, except in the north, where transplanting should be delayed until the first or second week in June, according to locality. Varieties of the dwarf bedding class may be planted as closely as 18ins. apart each way; but the charms, which are taller, need a space of 2½ft. to 3½ft. apart in which to develop fully. The former need no support other than a short stick at the outset; but in planting charms (and all other types, for that matter) a centre stake should be inserted in the position each plant is to occupy, and the young dahlia planted against it. As the plants commence to grow, three more stakes should be inserted round each one, slanting slightly outwards, and strands of string passed round them to support the growths.

Staking should be neat and unobtrusive, for nothing is more unsightly than careless staking in bed or border. Green painted stakes are useful, and their height should be slightly less than the individual varieties. Eventually the foliage should hide all stakes.

Plant firmly, and guard against slugs for the first week or two. Frequent shallow hoeings are beneficial, and unless it is considered too unsightly, a surface mulch of strawy manure or spent hops round each plant will conserve moisture and assist growth if applied about the middle of July. Although not essential, an occasional watering or feeding with liquid manure will be found beneficial at intervals throughout the season.

DWARF BEDDING DAHLIAS.

The first really dwarf dahlia to become popular was Coltness Gem, almost unknown a few years ago, but now planted more largely than any other variety in any type. Its rapid advance in public esteem is not surprising, for it possesses almost every attribute of the perfect bedding plant. It has an ideal habit of growth, blooms early and continues to flower until cut down by the first sharp frost. It carries its single bright crimson flowers well above the foliage on rigid wire-like stems, forms a shapely rounded plant which rarely exceeds 18ins. in height even at the end of the season. Only a comparatively few satisfactory dwarfs have been introduced, but it is quite certain that it is only a matter of time before we shall have a large number with the true "Coltness" habit and also the wide colour range which characterises all dahlias. Future dwarfs are not likely to be confined to single flowers; one firm at least is endeavouring to combine the beautiful semi-double form of the charms with the "Coltness" habit, and two or three of their 1927 introductions are very beautiful.

While Coltness Gem is undoubtedly the best variety at a low price, here are a few other dwarf bedders (or "mignons," as they are sometimes termed) which are all good:

Paisley Gem.—Very similar to Coltness Gem except in colour and shape. A light, bright scarlet semi-double flower, almost an orange scarlet. Very free flowering and erect, and slightly taller in growth than "Coltness."

Gipsy Maid.—A very free flowering, rich velvety black maroon, semi-double, 18ins.

Exquisite.—A pleasing shade of bright lilac pink with wiry, upright growth; 18ins.

Abingor Gem.—Best described as a bright orange counterpart of Coltness Gem; 18ins.

Salmon Beauty.—Many will like the dainty form of this novelty. It has single cosmea-like flowers of rich salmon, deepening to orange chestnut at the base of petals; 15ins. to 18ins. in height.

Histon Gem.—Semi-double flowers of an intense scarlet. A fine habit; 18ins.

Amber Queen.—A charming little dahlia, best described as a dwarf charm. The semi-double flowers are of an ivory salmon or salmon buff tone; 18ins.

Lady Aileen.—A single soft pink with a good habit; 18ins.

Golden Gleam.—One of the very best. It is extremely free, the plants being literally smothered in blooms. Rich golden orange "charm" shaped flowers; 20ins. high.

Piccaninni.—Single scarlet with dark bronzy foliage; 2ft.

Autumn Glory.—Rather tall, but very free flowering. Semi-double, rich crimson scarlet 20–24ins.

SMALL BEDDING SCHEMES CAN BE MADE VERY ATTRACTIVE BY THE USE OF MIGNON DAHLIAS IN VARIED COLOURINGS.

CHARM DAHLIAS.

This type was formerly known by the somewhat lengthy but perhaps more descriptive title of miniature peony-flowered. They are equally useful for bedding as for cut flowers. They are so free flowering that continual cutting will not detract from their bedding value. The blooms are semi-double, from 3ins. to 4ins. in diameter, borne erect well above the foliage on strong wiry stems. The bushy plants average about 3ft. in height. Although of comparatively recent introduction, the range of colouring is most remarkable, probably wider and more varied than in any other type. A few good novelties are:

Mamie.—Golden yellow, softly suffused salmon apricot, with a zone of chestnut scarlet at the base of petals; 3ft.

Clara Hart.—Brilliant crimson scarlet, 4ft.

Gloria.—Brilliant orange flame with deeper base; 3½ft.

Margaret.—Golden yellow centre, with petals flushed, "rayed" and tipped with gold. Suffused orange pink towards the tips of petals; 3½ft.

Vedas.—Clear sulphur yellow; 3½ft.

Dot.—Deep lemon, flushed soft salmon biscuit; 3ft.

Olwen.—Orange fawn, base striped and flamed chestnut; 3ft.

Irma.—Soft satin rose, lightly flamed orange chestnut at base. A variety to make particular note of for cut flower purposes; 3½ft.

Excellent varieties, typical of the best charm type, at an inexpensive price (9d. or 1s. per plant) include:

Our Annie.—Shrimp pink on yellow ground; 2½ft. Still one of the very best.

Rosie.—Deep rosy pink; 3ft.

Dazzle.—Brilliant scarlet; 3½ft.

Electron.—Very uncommon and pleasing, orange scarlet "shot" electric violet.

Mrs. Ralph Wade.—Soft buff, flushed pink and suffused yellow, with chestnut zone at base of petals; 3ft.

Norah Bell.—Scarlet flame with yellow base; 3ft.

Charmer.—Orange salmon, 3½ft.

Picture.—Orange flame on gold with chestnut scarlet base; 2½ft.

Gladys Unwin.—Soft pink with lemon and chestnut base; 3ft.

Sophire.—White with small primrose zone at base.; 3ft.

PERENNIAL FLOWERS FOR CUTTING

WHERE any considerable quantity of cut flowers is required for house decoration, it is desirable, if possible, to set aside a piece of ground in the kitchen garden, or some other place not much in evidence, for plants specially suitable for the purpose. This, however, is not always practicable, in which case, when choosing plants for the borders, it must not be forgotten that they will have to "contrive a double debt to pay."

The perennial season may be said to begin in April with polyanthuses; single and double coloured primroses, charming when arranged in shallow bowls with mossy saxifrage; the pretty orange wallflowers, Cheiranthus Allionii, C. alpinus and C. Pamela Purshouse (a hybrid between the two first); Saxifraga cordifolius (megasea); Doronicum plantagineum excelsum and, towards the end of the month, Polygonatum officinale (the ordinary Solomon's Seal) and P. giganteum, its big brother; together with the earliest of the dicentras, the rosy purple eximia. In May come the first flag irises—all the irises, except perhaps the common blue flag, are admirable for cutting and should be as largely grown as possible—and the earliest of the peonies, corallina, the so-called Steep Holm Peony. This has comparatively small single flowers of a vivid magenta crimson which is certainly rather crude, but, when mingled with plenty of pretty blue-green leaves in, say, a big double-handled cider mug of brown glazed ware, the effect is very gay and pleasing. P. corallina is followed at the end of May by the double and single European peonies, the oldest type,—the peony of cottage gardens, with its huge flowers, light and dark crimson and flesh pink, made up of myriads of petals—being the first to open. Other May flowers suitable for cutting are Stachys (otherwise Betonica) grandiflora, rather coarse, and the red purple of the spikes just a little dingy, but effective in a mass and lasting well in water; and Aster alpinus, the deep lavender blue starry flowers of which are ideal for small vases.

In June we get the single and double Chinese peonies, loveliest of their kind and particularly beautiful when combined with delphiniums: a tall trumpet-shaped vase of clear glass filled with sky blue delphiniums of the Belladonna class and soft pink peonies such as Kelway's Lady of the West or Lovely, for instance, is a real joy to the eye. Most delphiniums are good for house decoration, alone or with other flowers; but the darker ones, especially those that have much purple in them, are apt to look dull under artificial light. Perhaps it may be suggested here that for cutting unnamed seedling delphiniums of first-class strains, such as are supplied by Messrs. Blackmore and Langdon and other firms, are quite satisfactory—or, at least, a very large percentage of them are—and they are, of course, far less expensive than the named varieties.

In June, too, come the lupins, polyphyllus and the hybrids, polyphyllus × arboreus, in their many colours, the most striking being the new Prince of Orange; the pyrethrums; the long-spurred aquilegias, which make a dainty dinner-table decoration in tall old-fashioned champagne glasses; Campanula latiloba; and Papaver orientale. The big poppies are as uncertain in their behaviour when cut as the lesser ones, and should be treated in the same way, gathering them when only a streak of colour is visible in the calyx, and late in the evening, dipping the ends of the stems into boiling water at once and keeping them in a dark, cool place until the following morning. The varieties that are most reliable are those with stout, erect stems—Perry's May Sadler, for example; the gorgeous blood red Goliath and P. bracteatum Crimson King. The well known Mrs. Perry is less sturdy of habit than the poppies just mentioned, but its soft crimson pink colour is very delicate and goes well with a silvery lilac English iris, such as Tantalus or Queen Alexandra, or with Iris dalmatica Princess Beatrice. Two other June-flowering plants, the decorative value of which is not fully appreciated perhaps, are Phlomis Samia, with pale yellow whorls of blossom on long stalks, and Thermopsis montana, which has bright golden lupin-like flowers. These two, together with Iris ochroleuca and some branches of dark foliage such as that of Prunus Pissardi or copper beech, make an admirable group for one of the big blue and white Dutch Delft jars in which tobacconists kept their stock of snuff in bygone days. Among June flowers suitable for small vases and bowls there are the old fringed white pink; the blue Catananche cœrulea (Cupid's Dart, so called because it was an ingredient in the love-potions of the dark ages); Papaver nudicaule, the Iceland poppy; Meconopsis cambrica, the Welsh poppy; and Lychnis Flos-cuculi fl. pl., with its pretty little rose pink rosettes.

All through July there is an almost overwhelming abundance of flowers for cutting. To the old white pinks succeed the Allwoodii hybrids, which will continue to bloom during the rest of the summer; while among other desirable things are Coreopsis grandiflora and C. auriculata superba; Malva moschata alba; Sidalcea Rosy Gem, Sussex Gem and candida—these three combine well with Heuchera Rose Cavalieo; the campanulas, including the dark violet glomerata, persicifolia (of this the best varieties are Telham Beauty and Ryburgh Bells, both lavender blue, and the new white Fleur de Neige), latifolia and, from the end of July to the end of August, lactiflora, with its big heads of pale lavender flowers; the erigerons, Fontainebleau (bright lavender), Quakeress (rosy lavender), Pink Pearl and Edina (white); and the invaluable achilleas, A. Ptarmica Perry's White and A. millefolium Cerise Queen, these being among the most lasting of all flowers in the cut state.

LUPINS AND IRISES PROVIDE A WEALTH OF BLOOM FOR CUTTING IN EARLY SUMMER.

SOFT PINK PEONIES ARE BEAUTIFUL EITHER AS BORDER PLANTS OR CUT FLOWERS.

Digitized by Google

Several varieties of eryngium should be grown, including EE. Oliverianum superbum, amethystinum, planum (which has branching heads of small dark metallic blue flowers and is, perhaps, the prettiest of all); and the new hybrid, Violetta, the colour of which is more purple than blue. Eryngiums accord well with many of the soft blue and avender delphiniums, or, if a marked contrast is preferred, they may be combined with the bright scarlet of Lychnis chalcedonicum or the fiery orange of gaillardias. Of the latter, three good varieties are Barr's Taplow Red, Sydenham's Mrs. Mackellar, and Allen's Tangerine.

August is the month of phloxes, but, fine things as they are, they are not entirely without drawbacks when used for indoor decoration They drop their petals rather speedily, and many people object to their scent, which, although not strong, is a little heavy in a room. However, here is a list of half a dozen desirable varieties: Baron van Heeckeren, salmon pink; Milly van Hoboken, pure pink; Le Mahdi, red purple; Miss Ellen Willmott, pale lavender; Coquelicot, orange scarlet; Europa or Mia Ruys, white. The earliest of the heleniums—all are excellent for cutting—is the dwarf H. pumilum aurantiacum, which begins to flower in July and continues to do so until well into September. Helenium Crimson Beauty is also of low stature, but blooms later, as do the tall varieties Riverton Gem and Riverton Beauty.

Other good August and September flowering plants are Heliopsis Excelsior; Chrysanthemum maximum Barr's White Knight and Blackmore and Langdon's Arthur Chapman, both superior to the old King Edward. The pink and white flowers of Anemone japonica are rather given to droop unaccountably and annoyingly in water, but they are too pretty when well behaved to be barred. Whirlwind (white) and Mont Rocs (pink) are good.

With September come the rudbeckias, ranging from the 6ft. R. lacineata and its double variety Golden Glow, to the dwarf R. speciosa (syn. Newmanii). All have great decorative value, the deep orange yellow, star-like flowers of speciosa contrasting well with Aster Amellus King George and sprays of one of the feathe y Michaelmas daisies, such as Aster ericoides Silver Gem or Chastity, or A. cordifolius Ideal. The single or nearly single asters are, on the whole, more satisfactory for cutting than the double ones, and among the best for the purpose are Climax and King of the Belgians, both lavender blue. Grey Lady, opalescent lavender; Barr's Pink, one of the finest Michaelmas daisies so far raised; Mons, deep rose; and a new introduction of Mr. Ernest Ballard's, Mrs. George Munro, a good white.

The majority of the solidagos are too coarse to be desirable except in the wild garden, but the new S. Ballardii is a hybrid which is refined enough to be admitted into the border. The giant groundsel, Senecio tanguticus, has the same fault as the solidagos, but its handsome golden spikes last long and are exceedingly striking in a tall copper jar, or even in a brown ware pitcher, especially if combined with the shining purple brown leaves of Berberis Aquifolium (Mahonia) and sprays of deep orange yellow chrysanthemums. The small single annual sunflowers are better for cutting than the perennials, but the double helianthus Miss Mellish is an exception among the latter. One of the latest autumn flowers to open is the moon daisy, Chrysanthemum (syn. pyrethrum) uliginosum; but in a mild season ordinary outdoor chrysanthemums can be picked up to the middle of November.

Given some slight protection in the way of canvas stretched on bamboos, the Christmas daisy (Aster grandiflorus) will open its rich violet flowers as late as the first or even the second week in December, but with it the year's pageant of flowers may be said to end, and the hellebores, Iris stylosa, winter aconite, and the winter-flowering shrubs must suffice to fill the gap until the February snowdrops mark the coming of spring.

For the purpose of mixing with cut flowers, gypsophila; the striped ribbon grass, which country people call Gardener's Garters; Thalictrum aquilegifolium and T. adiantifolium (both as pretty of foliage as they are poor of flower); the grey-leaved artemisias; santolina and sea lavender, should be grown.

R. E. HEAD.

DAHLIAS IN SCOTTISH GARDENS

WITH the advent of several new types of more or less decorative merit, the dahlia has advanced rapidly in public favour and it probably comes next to the rose and sweet pea in the estimation of amateur gardeners. Its present-day popularity may in great measure be traced to the creation of the collarette type in the beginning of the present century, followed by the introduction of the dwarf bedding variety, Coltness Gem. Subsequently the star and charm race came into prominence and this season has witnessed the distribution by Mr. Unwin of the latest novelty, obtained by crossing Coltness Gem with charm varieties. The cactus form which has been in cultivation for well nigh fifty years, has made comparatively little headway in the garden, but the once fashionable show dahlia still commands the admiration of older enthusiasts in Scotland, who grow it as an exhibition flower, for it continues as a class in the prize schedules of horticultural societies throughout the country.

At a recent meeting of the Royal Caledonian Society a member expressed the opinion that the dahlia was a much overrated subject for the garden. The principal objections which he urged against it were the absence of scent and the uncertain flowering period, which was liable to be brought to a rapid and premature close by a single night's frost in early autumn. Despite these defects, which are also applicable to the chrysanthemum and the gladioli, dahlias of one type or another are grown on a more extensive scale each succeeding season and as an indication of the demand it may be noted that Messrs. Dobbie and Co. alone raise over 150,000 plants annually from cuttings, while the magnitude of the nursery trade in Coltness and other "Gems" can only be conjectured.

This, however, is not a complete index of the popularity of the dahlia. Owing to easy methods of propagation it is a common practice of amateurs to raise their plants from seed and increase their stocks by cuttings or division in spring. The latter system finds favour with those growers who do not possess facilities for striking cuttings. A great deal depends on the object which the gardener has in view. Generally speaking the plants of collarette, cactus and decorative dahlias produce better quality blooms from an exhibitor's point of view when grown from cuttings. Pot roots start to flower earlier and give quite as much bloom, but the flowers are not of the same quality. Pompons, on the other hand, show less difference and then only in varieties that occasionally expose their centres. The lesson, therefore, to be learned by the exhibitor is to produce his plants from cuttings, while the cultivator who requires plants for garden decoration and cutting should raise them from pot roots.

PLANTING OUT POT GROWN DAHLIAS IN A SHELTERED POSITION.

But the only method open to the amateur who has neither greenhouse nor frame is to plant the tubers in the open ground. This process means later flowering and risk of injury to the young growth in the event of May frosts. The climate is so uncertain and variable in Scotland that it is useless attempting the specification of a safety line either as regards time or locality, for I know gardens in south Ayrshire where dahlias have been grown out of doors for several years without disturbance or protection in winter. Actual experience in each locality is therefore the only reliable guide to follow in regard to the period of planting.

Small gardens seldom offer a choice of situation, but wherever possible select a position that is sheltered from high winds. A simple line of sweet peas or a wooden trellis clothed with rambler roses provide a screen that combines the useful with the ornamental, failing which the dimensions of an average hedge contribute to the protection of the plants. Individual specimens may be arranged in a herbaceous border, but where space permits, dahlias grown in groups are more effective if the embellishment of the garden is to be studied.

When collarette and decorative sorts are grown for that specific purpose, the soil must not be made too rich by digging in a liberal dressing of farmyard or stable manure. In that way disappointments lie. If the ground was thoroughly manured in the previous year, no further treatment is required beyond digging to a depth of 12ins. to 18ins. and the distribution of a light dressing of slaked lime before the soil is broken up. When coming into bloom the plants respond readily to applications of weak liquid manure and the more you feed the better will be the quantity and quality of the flowers. Moisture, of course, is an essential element and in a dry season water and liquid manure should be given alternately during the period of bloom.

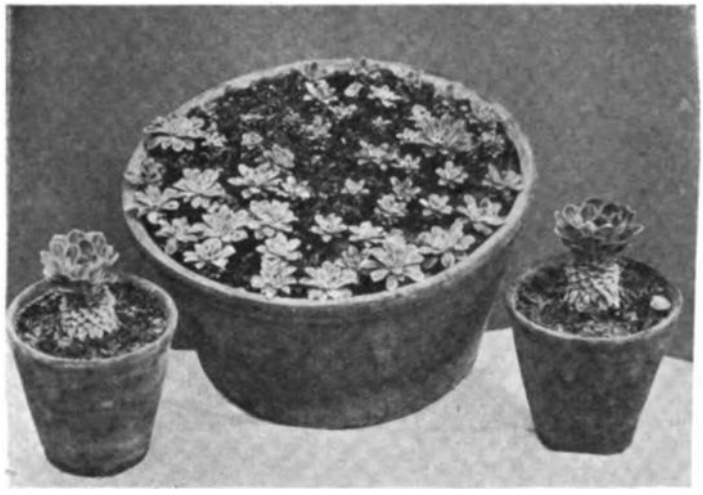
ALPINE PLANTS FROM SEED

THE ever increasing popularity of rock and alpine plants with all amateur gardeners, calls for some little account of the different means of obtaining and propagating these plants and no method is so fascinating as that of raising them from seed. By this method desirable plants may be increased a hundredfold in one sowing. For example, one seed pod of a saxifrage or gentian will produce anything up to a hundred seedlings; on the other hand you may not get one to germinate, although this will not happen if reasonable care is taken in selecting and sowing the seeds.

A word concerning the methods used in seed sowing may be of some service to the reader and I hope may be the means to success where failure has hitherto resulted. The first thing to be done is to select the plant and then the flowers from which to take the seed. The plant must be the healthiest in the batch and only the best flowers should be retained; they will frequently vary in colour or formation of petal even if they are on the same plant. From three to six flowers will be enough for most things, removing the remainder if possible; this will take some of the work off the plant and your seeds will mature more rapidly. Pick the seed directly it ripens; if you are not quite sure, when it is picked place it in full sun for a few hours. Seed should never be gathered when wet. The seed may now be shaken out on a clean piece of paper and picked over, removing all dust and any other foreign material, as this may contain other seeds which will pass unobserved when sowing. Fold the paper and name the seed clearly, or place in small envelopes, obtainable from all garden sundriesmen for this purpose. This will only be necessary if the grower has several subjects he wishes to increase and wants to make one sowing do for them all. Otherwise, I believe in sowing at once, which is nature's own way.

The question of what to sow the seed in is important. Seed pans from 3in. to 5ins. deep and 4ins. across are most suitable; care should be taken to see that they are clean and well drained by placing a large piece of flowerpot over the hole and fill to a fourth of the pan's depth with smaller crocks, covering these with half rotted leaves or fibre from the potting mould. It is most important to work with clean pots and ample drainage if one is to be successful in raising alpines from seed. Composts of soil should be mixed according to the likes of the plant, only lighter, if a little more sand, leaf-soil or peat for such as like it, is added, the whole passed through a ¼in. sieve, most plants will readily take to it and make fine fibrous roots. If it is convenient it is as well to sterilise the soil, by filling an ordinary saucepan with the soil and placing it on a stove for five or six hours, keeping the lid on. This will kill all bacteria and prevent liver-wort making its appearance so quickly. Fill the pans to within a ½in. of the top, making fairly firm, sow thinly and evenly, covering according to size of the seed, the smaller the seed the less covering required; some will not require covering at all. The pans should not be watered from overhead, but placed in a pail and the water allowed to percolate through. This will prevent the soil caking and the seedlings will not be so likely to damp off. The pans may now be placed in a cold frame with light shading day and night and kept close until they germinate, when air and light may be admitted gradually if a frame is not available, place outside in the shelter of a west or north wall or hedge with a piece of glass and paper over each pan. I have obtained good results from pans of seed that have lain dormant all the summer, by standing them right in the open in January and they have germinated in March.



RAISING SEEDLINGS OF SAXIFRAGA GRISEBACHII. THE SEEDLINGS THINNED OUT AND THEN POTTED UP SEPARATELY.

A few suitable subjects that come well from seed may be enumerated here and be of use to the reader. The mossy section of saxifrages seed freely from one good variety. The encrusted and Kabschia sections also germinate freely and a good percentage of true plants will be obtained. Saxifragas will germinate more readily without any covering. They are in most cases lime lovers and will attain their flowering stage in two or three years from time of sowing, except the mossy varieties, which will flower in a twelvemonth. Gentians are always admired and the joy and despair of all beginners. G. verna will germinate freely and sometimes flower the following year. The young seedlings will benefit with a dressing of additional leaf-soil. The seeds require little or no covering. The newer species, such as G. Farreri, sino ornata and Purdomi are all easily raised from seed and better plants are generally obtained by raising one's own plants by this means. Drabas come very easily from seed. D. imbricata is a fine rich yellow variety with mossy foliage; D. dedeana, with paper white flowers is slow to increase. Primula marginata is lovely in its margined foliage or its delicate lilac flowers and was the parent of such lovely plants as Linda Pope, which outshines its parent in foliage and flower. Primula J. H. Wilson, must not be overlooked, as its wealth of blooms are a feature in early April. This variety will come fairly true from seed. If the seed is sown on fine leaf-soil or on peat and sand, germination is much more rapid. Saxifrages, require a very open soil at all times. S. Grisebachii Wisley variety and S. longifolia soon make good sized plants if potted off singly when they attain the size of a sixpence. Raising alpines from seed is an easy and rapid way of increasing ones' collection of alpines. J. W.

THE BUSY MAN'S PAGE

May Reminders.

SOW dwarf French beans in succession and thin out the early sowings 6ins. to 8ins. apart.

Towards the end of the month sow scarlet runner beans. Mark out the row a fortnight beforehand and dust a handful of superphosphate to each yard run.

Sowings of long sorts of beet may be made.

Carrots may still be sown and earlier sowings should be thinned.

Get celery trenches ready for the first batch of plants. Let them be a foot wide and deep and work in a dressing of manure.

All peas should be provided with sticks when the plants are 4ins. high.

Begin to earth up potatoes when the plants are 6ins. high. At the same time it is a good thing to scatter nitrate of soda or sulphate of ammonia at the rate of 1 oz. per yard run.

Tomatoes should be kept near the glass to make them sturdy and on no account must they be allowed to suffer from want of water.

Apples which have set their fruits should be examined and at the first trace of caterpillar, sprayed with Paris Green.

A mulching of manure will help the swelling fruits of gooseberries and currants. Keep a sharp look-out for caterpillars.

Strawberries should have a mulching of strawy manure or clean straw.

Annuals may still be sown and half-hardy sorts can be sown in the open, for late blooming.

Bedding plants may be put out, calceolarias early, geraniums, lobelias, verbenas, etc., late in the month.

Sow Canterbury bells, sweet williams and wallflowers. Sow thinly and when the seedlings are established, give them quite four inches apart in the nursery bed.

Dahlias may be put out about the third week in the month. Be sure and water them in well.

Support sweet peas with twiggy sticks, water in dry weather, and give a mulching of manure.

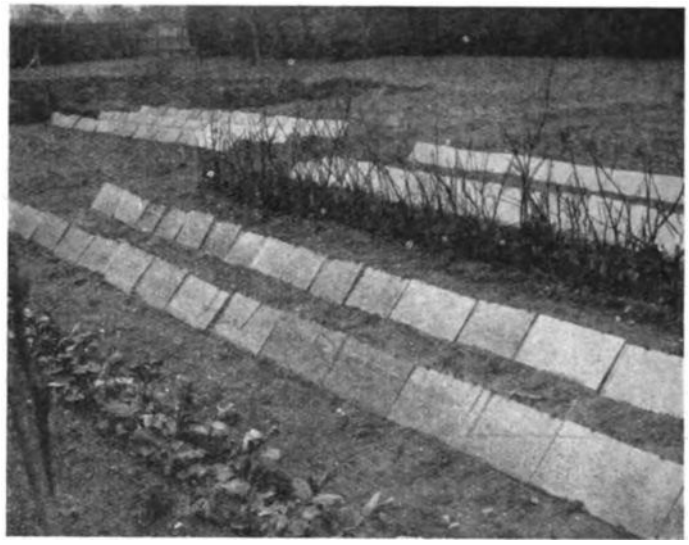
Go over violas and pansies each day, removing all the fading blooms, then a succession of flowers will be assured.

Protecting and Raising Seedlings.

A Handy Cloche.

THE man who has very little time to give to his garden will welcome any device that makes for easy work. In the simple and pleasant garden operation of raising seeds a certain amount of constant attention is needed to secure the maximum of results. In this connection the Chase Continuous Cloche proves a welcome asset. The writer has personally inspected the use and working of these cloches and can recommend them to the busy man. They protect early growths from frost, rain, wind, birds, animals and insects; they bring you earlier, bigger, better crops—and extra crops, too; they enable you to sow all the year round; they make you certain of your results; they save seeds, time, trouble and expense; they involve no extra labour; and they do not require large storage space.

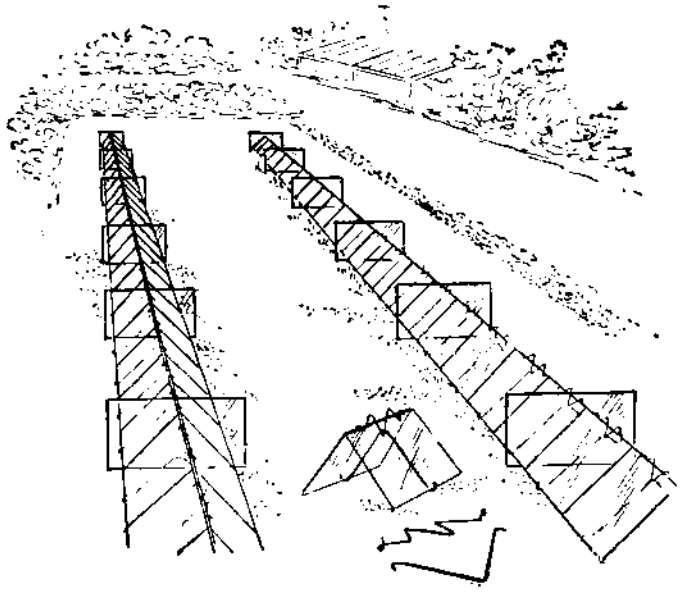
There are a hundred and one ways in which they can be used in a garden. Made of steel wire, the glasses are held firmly in position. The strongest winds do not move them, and a very important point to amateurs who are anxious to secure sturdy seedlings is that they do not "draw" the seedlings. Light can reach the plants on all sides. The "crack of air," to use an old gardener's phrase, prevents scorching. They are less expensive than the Continental bell-shaped cloches in that, if a sheet of glass is broken, it is easily replaced.



ROWS OF PEAS AND BEAN SEEDLINGS RAISED UNDER CLOCHES.
Where these have been removed the advanced growth can be seen.

Preparing for the Dahlias.

TO secure the best results it is desirable that the flowering sites of the dahlias should be well prepared in advance. Dahlias naturally prefer a soil which is inclined to be heavy, but it is essential that this should be well drained and thoroughly worked. The positions should be fully exposed, as dahlias are great sun lovers. If the ground is of a suitably heavy nature, it need only be dug deeply and enriched with old farmyard manure. If this step was not taken in the fall no time should be lost in getting the work in hand. When the soil is very light in character the spring is quite the best time for digging it. Work in rich loam and old farmyard manure to give the ground staying power. Dahlias are, of course, often employed in mixed borders, and here the actual places where the plants are to be set must be specially prepared. Note deep digging is very essential, as the plants like to send their roots down to a considerable distance and, when they can do this, the vigour of growth is greater and the flowers are much more freely produced. Allow plenty of room for each plant, the taller kinds being placed quite 3ft. apart and the others about a foot less, except the mignon dahlias, which will not need more than 15ins.



STEEL RIM SUPPORT FOR SECURING THE SHEETS OF GLASS. ROWS OF SEEDS AND SEEDLINGS ARE EASILY PROTECTED IN THIS WAY.

How to Grow Fine Polyanthuses and Primroses.

ALTHOUGH these plants are hardy perennials, they are not at all a success, as old specimens, in some soils. Even where they do live and thrive through the summer months, their flowers are much smaller than those of young stock. So it is much the best plan to raise young plants every year, even where old ones are retained. In medium to heavy soils the polyanthus and primrose grow much more freely than in light, sandy ones. Those cultivators who have to deal with light land should prepare a plot for them to grow in during the summer months, where they will be cooler than in any other part of the garden, as the summer weather is the most trying for the plants. Such soil should be prepared now and the seeds ought to be sown as soon as possible so that the resultant seedlings will have a long time in which to grow. A common mistake is that of sowing the seeds too late and then weakening them by undue coddling in a too warm position. The seeds may be sown in pots, pans or boxes. All seeds of the primula family are a long time in germinating and, as some seeds germinate sooner than others, it is advisable to sow them almost 1 in. apart, then the forward seedlings can be transplanted without the others being disturbed. The seed vessels should be clean and dry, also the crocks; drainage is an important item. Good loam, free from weed seeds, two-thirds, and sweet leaf-soil one-third, will make a suitable compost. Three-parts fill the pan or box, level the soil, water it and one hour afterwards sow the seeds, as suggested, thinly. Cover them with a quarter of an inch of soil, place a sheet of glass on the vessel, then some paper and shade, too, from bright sunshine. Transplant twice before the final planting.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

The Rock Garden.

Replacing the Spring Flowers.

IN the early part of the year the rock garden is a blaze of colour. Masses of purple aubrietia, white rock cress, golden crocuses, blue scillas, and yellow and white narcissi make the rockery the showiest part of the garden. But unless we prepare to fill the gaps which will be left when some of these floral beauties are over, the rock garden may lose a great deal of its charm later in the season. This is a pity, for though the herbaceous borders will to some extent make up for the deficiency in other parts of the garden, there is really no reason why the rock garden should ever be "at its worst," for there are at all times some plants which will add colour and interest to this feature. Now that the time for sowing half-hardy annuals has arrived, it should be possible to fill many of the bare places in the rockery by sowing a few seeds of dwarf annuals. Dwarf nasturtiums (which can be obtained in selected colours) sown now in the places where crocuses or scillas are dying down will not interfere with the natural ripening off of these bulbs, and will take their place and give a good show of bloom during late summer and early autumn. A few seeds of nemophila, night-scented stock, Californian poppy, Virginian stock or any dwarf annuals can be used here and there in this way among the dying spring flowers.

Transplanted Seedlings.

An even more rapid effect can be obtained by using a few of the seedlings raised for summer bedding. A few seedlings of alyssum, for instance, or lobelia, dwarf antirrhinum, French marigolds or any similar plants such as would be used for edging the borders are equally effective if planted out in little groups on the rockery. If you have such rank-growing subjects as stonecrops already growing, you will doubtless find it advisable to remove large portions of them occasionally, and if this is done now the bare space left can be used for transplanted seedlings. Lightly fork over the old patch of soil and add a little fresh soil before the transplanting is done.

Increasing Stocks of Perennials.

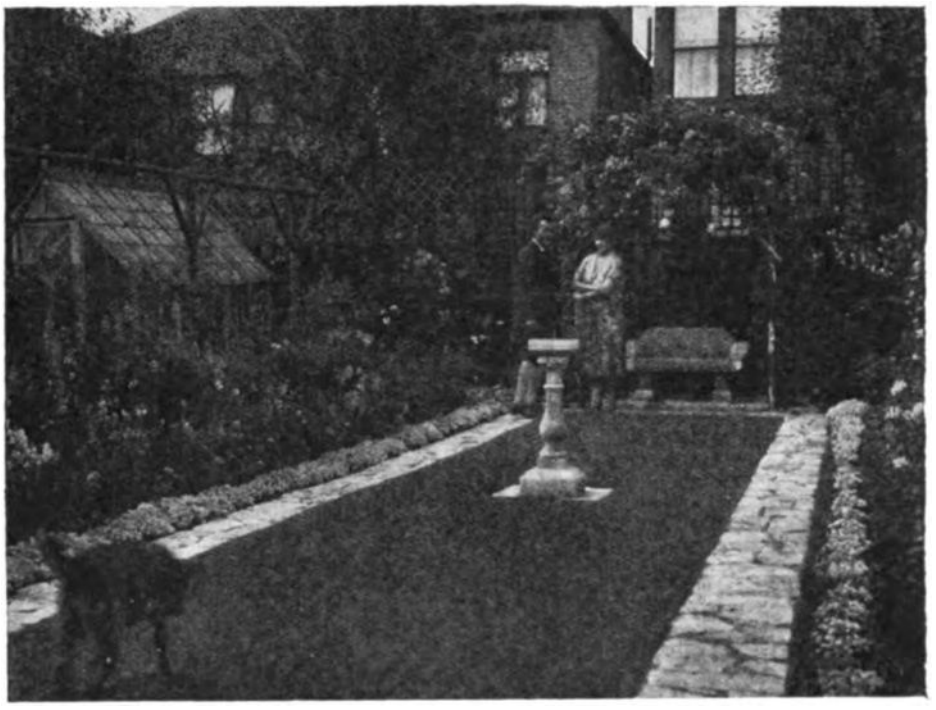
Should you wish to increase your stock of spring "carpeting" plants, the time to do this is after they have ceased flowering. Cuttings of arabis and aubrietia will root readily if they can be kept close for a short time so that they do not get dry overhead. If you cannot spare a frame for these, put the cuttings in a hollowed out nursery bed about 6ins. below soil level, and cover them with a sheet of glass. Shade them from bright sunshine for a week or two to prevent scorching. When rooted, the cuttings may be transplanted to their permanent quarters or planted out in rows so that they can develop ready for autumn planting.

A Garden of Welcome.

WHEN you enter a garden in midsummer, you feel instinctively that you know the character of the owner. Some gardens are slovenly, some are neat. Some are filled with rare blooms, but are uninviting. But such a garden as we see here seems to welcome you with a smiling "Come In." This particular garden was entered for competition in the summer of 1926 and the judge is seen in the picture on his tour of inspection. Among the many praiseworthy features of the garden are its simplicity of design, its friendliness as emphasised by the shaded seat, its neatness and the charm of its well filled borders. It is not overloaded with garden ornaments, the centre sundial and stone seat seem "just right," and the straight paths make the garden appear longer than it really is.

Small wonder that when a judge visits such a garden on a hot summer's day he feels loth to depart! Well kept turf adds considerably to the beauty of the garden. In many gardens the grass is made to serve as path, instead of the crazy paving, but the latter has an advantage in wet weather, as it enables one to visit the flower border without carrying mud into the house.

The picture shows the value of sweet alyssum as an edging. Such an edge can be planted with crocuses for early spring. These would be allowed to die off naturally, to be replaced by seedlings of sweet alyssum raised in a nursery bed in a corner of the garden.



THE MORE SIMPLE THE DESIGN, THE MORE CHARMING THE GARDEN.

Pests and Diseases.

A FUNGUS which causes considerable damage to rose trees, hops, vines, etc., is known as mildew (mealy-dew), so-called from its appearance. The first sign of the disease is the appearance of greyish spots on the young leaves and shoots. These spread and finally cover the leaf with a fine powdery layer. Often the young buds are affected, and growth and flower production are injured. Liver of sulphur (potassium sulphide) dissolved in water, 1 oz. to three gallons, makes an effective spray. Dustings with flowers of sulphur is also a useful remedy. Russian pathologists advocate spraying with bicarbonate of soda—an ounce dissolved in every ten gallons of water.

Finger-and-Toe.

This is a serious fungus disease among cabbages and other members of that family (cruciferæ). It causes the roots to swell enormously, hence the various names, "Club Root" and "Finger-and-Toe." Numerous experiments have shown that slaked lime will destroy the spores of this disease in infested land. In fact, its presence may be regarded as an indication of a deficiency of lime in the soil. In addition, if the seedlings of cauliflowers and cabbages, etc., are raised in soil that has been well salted (they are seaside plants and like salt), they are less likely to be attacked when planted out.

Silver Leaf on Plums.

The appearance of silvery leaves on plum trees might appeal to the artistic sense if it were not a sign that the trees were attacked by an internal fungus malady. Affected branches gradually die back, and as the disease spreads the whole tree may be killed. Curious purply-mauve growths appearing on the trunk represent the mature stage. These, if they remain, scatter spores which are blown to other trees and enter by means of injuries or fissures in the bark. No cure is known for the disease at present, but the disease should be controlled by destroying trees badly attacked, or cutting away and burning all silvered branches in case of slight attacks. Wounds and cuts on other trees should be painted over with Stockholm tar or creosote.

Rose Pests.

Roses are rapidly forming flowers. If maggots and green fly are troublesome, spray with nicotine wash. This is also a remedy for thrips, leaf-hoppers and cuckoo-spits. Dissolve 2 oz. of soft soap in a little hot water. Add 1 oz. of nicotine (obtainable from leading seedsmen) and make up to ten gallons with water. Spray the bushes thoroughly, it will not harm the flowers. When hybrid tea roses (such as Red Letter Day) are cut for decorative purposes, cut them with fairly long stems—that is to say, prune them at the same time. They will then break out again lower down and give a second crop of flowers. At the same time, a little artificial fertiliser sprinkled on the soil round the bushes and hoed in will help the plants to develop finer flowers.

WORK IN THE FLOWER GARDEN

May Sowings: Plants for the Herbaceous Border.

IF the herbaceous border has room for a few more plants, here are some fine flowers to include in your seed list: Aquilegias, pyrethrums, lupins, hollyhocks, Gypsophila paniculata, sweet williams, delphiniums, campanulas in variety, gaillardias of various kinds, and Iceland poppies.

First prepare a fine seed bed, making the soil moderately firm and level. To this end the rake will be used effectively, while any lumps of soil that resist the rake may be crushed with spade or trowel, etc. A sprinkling of sand always helps to make a stiff soil become more friable. If some compost heap or rotted manure has been dug in, the soil will be in good trim for flower growing. A sprinkling of garden fertiliser may otherwise be used. Having produced a good firm seed-bed of fine tilth, just make a slight scratch for the tiny seeds, and for the larger ones drills ½in. to ¾in. deep. Sow in rows 10ins. to 12ins. apart; but in small plots the seeds may be scattered broadcast. If the ground is very dry, it will be advisable to water it overnight. Sow the seeds thinly, and lightly cover them with the rake. The very small seeds may be simply covered with a dusting of fine sifted soil and sand.

It will assist germination if the seed bed is kept moist and covered with a straw mat or a sheet of grey paper. Remove the covering when the seedlings begin to appear. Prick out the seedlings before they become over-crowded. But first water both the seed bed and the bed the seedlings are to be transferred to. Plant about 8ins. apart either way. They can then be lifted later on with a goodly ball of earth at their roots. The bed can also be kept free from weeds by hoeing.—J. W.

May Jottings: Flower Bed and Border.

THE timely staking of all those flowers that need support may save a lot of disappointment, if heavy thunder showers are experienced. What a sorry spectacle some of our fine herbaceous subjects present when caught unstaked by heavy rain. Pyrethrums with their heavy blooms, Oriental poppies, their large dazzling flowers dashed to pieces; peonies twisted and broken; and many other tall-growing subjects that timely staking might have saved.

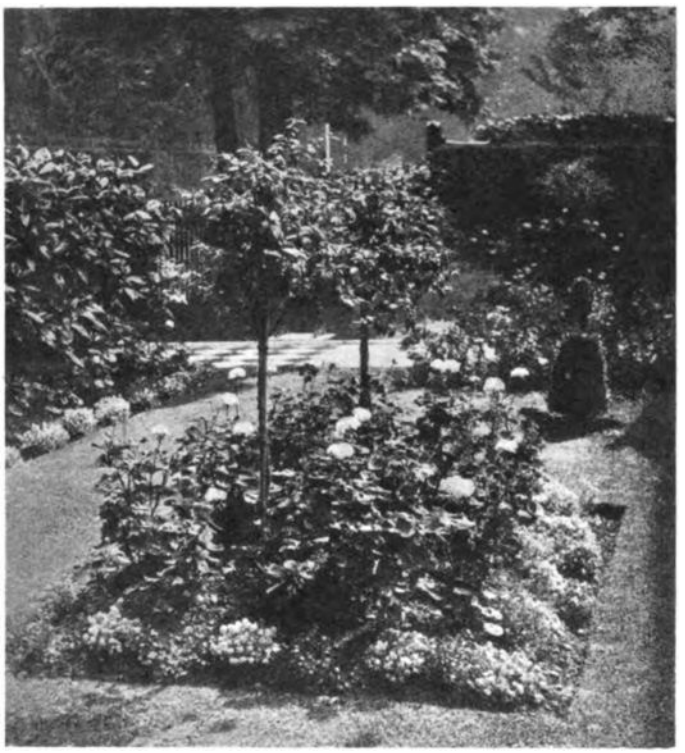
Roses will need some attention in May, as green fly is often very troublesome. A strong solution of soft soap or a good brand of insecticide are effective in keeping the fly in check. Apply the suds lukewarm during the afternoon and evening when the weather is mild or calm. Two ounces of soft soap to a gallon of water makes a good solution. One application may suffice, unless the roses are badly infested.

When dibbling out small seedlings that require planting again when larger grown, a good quantity of leaf-soil should be used, so that the plants will make plenty of roots and lift with a ball of soil attached to them. Instead of leaf-mould, a little fine turfy loam or a little well rotted manure may be used. Even in a dry season, plants will grow better when treated thus. It is always advisable to water the seedlings before pricking them out, and give them a little more water in their new position.

Bedding plants must be well hardened off before they are planted out. Even the hardiest of kinds grown under glass, in frame or greenhouse, must be gradually seasoned to an open-air life. In northern and cold districts tender subjects may not safely be exposed over-night before the end of May or the first week of June. Do not water every plant when watering, unless the soil is quite dry. If pot plants are kept continuously sodden, the soil gets sour.

A Fine Foliage Plant.

THOSE who are seeking for a plant with fine foliage should certainly consider the claims of Rodgersia podophylla. This plant, which is a native of Japan and perfectly hardy, bears leaves which measure a foot or more across and are cleft into five broad divisions. The bronzy green hue of the foliage renders the rodgersia very distinct from any other hardy plant. In a fine example the stalks bearing the leaves may be as much as 4ft. or more in height, and in any case they are rarely less than 2ft. The white flowers which, individually, are inconspicuous, are produced on tall branching spikes of a distinctive character, which makes them striking. One grows rodgersia chiefly for the sake of its foliage and the treatment should be directed towards securing a fine leafage. The rodgersia flourishes best in a peaty soil and grows most lustily where there is an abundance of moisture. On the whole, the best specimens are seen in somewhat shaded positions. The plant is of a herbaceous habit, although the leaves hang on well into the late autumn. Propagation is easily carried out by dividing the thick, fleshy, underground stems in the spring. A second species is sometimes seen in cultivation, and this is called R. pinnata. This is not such a striking plant as the first-named, for the leaves are smaller and the flowers are of a greenish white colour.—L. B.



A SMALL FRONT GARDEN WITH AN ATTRACTIVE SUMMER BED OF GERANIUMS AND STANDARD FUCHSIAS EDGED WITH ALYSSUM.

Standard Greenhouse Plants for Bedding Out.

SO many bedding schemes have a flat appearance, because of the monotony of dwarf plants, perhaps of not a particularly interesting character; a break by way of a tall plant would immediately convert the uninteresting bed into something attractive, especially if the tall subject be a standard plant that one does not often see outdoors or associate with outdoor gardening.

As a simple example of common usage in bedding schemes, the standard fuchsia illustrates the point. At the same time, some of the more choice fuchsias rarely seen outside a glasshouse might be thus employed to brighten the summer garden. Then there are standard heliotropes, brugmansias, geraniums and such plants as streptosolens and plumbagos—in fact, any hard-wooded plant—may be trained so as to occupy a place of vantage in bed or border each summer.

The standards are fairly easily trained, starting with the small plant, either from the seedling or cutting stage, and, by means of removing all shoots that appear on the sides of the stem, keep the energies of the plant to the production of a head of shoots only, leaving the stem bare. The stem grows, carrying the head higher and higher, until is evolved the typical standard that is so useful in many ways.

This may take some time, and a shorter cut would be to purchase standard trees from the nurseryman, ready for immediate effect. Not only do such plants help bedding schemes, but they are also useful for garden vases, tubs, as well as for standing in their pots upon verandas, terraces and porches.

The Decorative Aubrietia or Rock Cress.

Divide the Plants after Flowering.

THERE are quite a number of varieties of aubrietia, and few plants give a better return for a small outlay. We must look in the garden to see them in all their glory, because it is a plant that never does itself justice on the exhibition bench. That they are easily grown is beyond doubt, and if cut hard back after flowering, another but lesser crop of blooms appears. The chief flowering season, however, is from April till June, so anyone contemplating adding more varieties should procure them without further delay. They are strongly recommended for draping large stones in the rock garden and they are also seen to great advantage on old walls, where the cascades of rich blue and violet flowers are brought more or less level with the eye. They are also useful for covering banks, and are ideal for the front of borders, while they may be employed as a groundwork for tulips, etc., in beds.

An old variety, but still among the best is Dr. Mules, a rich violet purple; it possesses all the attributes of a first-rate garden plant, and if I had to confine myself to one aubrietia, this would be my choice. In pleasing contrast will be found Crimson King, while Lavender is most exquisite, with its lavender blue flowers, which are larger than most, but quite freely produced. Another noteworthy variety is Prichard's A1, a purple,

Digitized by Google

with white eye; and quite distinct is Mrs. Lloyd Edwards, a deep violet purple; while perhaps the best of the pink shades is Lissadel Pink. There are other forms, in fact each nurseryman seems to have his own particular varieties, but those quoted may be considered to have stood the test of time and are worthy of a place in every garden, however small. Aubrietias may be divided and replanted soon after flowering, or the better plan would be to cut back the plants when blooming has ceased and directly the new basal growths appear to use them as cuttings, which root readily in a cold frame, or on a partially shaded border.—CHEPSTOW.

Clematis montana rubens.

FOR this delightful introduction we are indebted to the late firm of Messrs. J. Veitch and Sons, Chelsea, who found it in China during the early 'nineties. It is a vigorous climber, and is admirably suited for covering old trees, arches, rough supports such as oak branches, sheds and walls generally. The deep rose-coloured flowers are produced in abundance during the month of May, and the blooms are slightly larger than those of the white species, C. montana. The foliage and young stems are also slighly darker than is found in the type.

There is also a form known as Wilsoni, which produces its pearly white blossoms at the end of June and early July.

The clematis family as a whole enjoy a rich loamy soil, preferably one of a calcareous nature, so where the rooting medium is known to be deficient in lime, a sprinkling of air-slaked lime or old mortar rubble should be added at the time of planting. This work can be carried out at any period, owing to the fact that clematises are usually pot-grown till they reach their final station. C. montana and its varieties can be increased by seeds and cuttings; the latter will form roots during the month of July in a cold frame. When raising the variety rubens from seeds, considerable variation in colour will be noticed in the progeny; but many will be quite equal to the parent, both in colour, vigour and size of flower. These clematises blossom from the nodes of the pervious year's growth, so where any pruning is desirable it should be done immediately after flowering, otherwise many flowers will be sacrificed if such an operation is left till the autumn or spring.

C. montana rubens is a beautiful climbing plant, and an isolated example near the lawn is very effective. In such surroundings it should be allowed to ramble over an old tree stump or a tripod of rustic wood.—W.

A Decorative Annual for Edging.

Seeds may be sown now in the open ground where the plants are to flower.

A PRETTY annual that deserves more general cultivation is Platystemon californicus. As it is of trailing habit, it has something of the same effect as another Californian, the better known Limnanthes Douglasi. But, whereas limnanthes is within the geranium order, platystemon is allied to the poppies. The lemon white bloom, fully expanded in the earlier hours of the day, is 1½ins. across, with a bunch of stamens of the same colour and a yellow blotch at the base of each petal. The leaves are long and narrow, greyish and hairy. It can be sown in the autumn or spring, and, when once established, may be trusted to come again, year by year, in the same place.—G. J.

A SHOWY AND DWARF ANNUAL, PLATYSTEMON CALIFORNICUS.
Suitable for edgings or clumps in the border.

Mimulus for a Moist Situation.

MANY gardens contain corners and borders which are always more or less moist, where certain subjects will not thrive so well as they do in other parts. Here, however, will be found ideal places for the mimulus or monkey-flowers. They will also succeed in bogs by the water-side; but especially are they at home in damp borders. There is a class of giant forms with enormous flowers in a variety of shades and colours, which are readily raised from seeds, and which, in the south and west, usually withstand the winter, and it is from these plants that a fine display is secured throughout the summer months. They are strongly recommended, but I would also call attention to the lesser known varieties of which several have been raised during recent years. For sheer brilliance of colour they have few equals, and are especially effective in moist nooks on the rock garden, and as isolated colonies in the flower border. A very fine one is Dwarf Scarlet, compact in growth, free flowering, and, moreover, it comes quite true from seeds. Another favourite of mine is Brilliant, a form with small crimson flowers. Colt Bee is a fine shade of pure rose; while Wargrave Fire Flame, which received an award of merit from the Royal Horticultural Society, is coppery scarlet with a yellow throat. Scarlet Queen is brilliant orange scarlet and a very profuse bloomer; and Coronation bears numerous rich carmine rose flowers which are most attractive. All these florists' varieties are dwarf, ranging in height from 6ins. to 9ins. They are easily grown, but towards the autumn a few cuttings should be taken and given the protection of a cold frame during the winter months. Although many of them would pass through the winter safely, it is a wise precaution to secure the cuttings with a view of retaining the stock for the following year. Quite distinct from the above is M. Bartoniensis, a hybrid between M. Cardinalis and M. Lewisii, an ideal plant for the bog garden or border. It attains a height of about 2ft., and the dark rose flowers have carmine spots in the throat. Another good monkey-flower of the same height is M. cardinalis, an erect-growing plant with carmine scarlet flowers. All the mimulus begin to bloom about June and continue till the autumn.

The favourite flower of our grandmothers must not be forgotten, viz., the musk, or M. moschatus. For years pots of this plant were the delight of many cottage windows; but, alas! in losing its exquisite perfume it lost most of its charm, till now it is rarely honoured by being arranged with the cottager's flowers. If any Continental or American reader possesses a stock of plants with the true old musk scent, a few specimens would be readily welcomed in this country.—T. W. BRISCOE.

CLEMATIS MONTANA RUBENS IS A FIRST-RATE PLANT FOR CLOTHING A HOUSE WALL OR ANY TRELLIS WORK IN THE GARDEN.
It may be purchased in pots and planted out now.

POPPIES FOR THE BORDER

AMONG the handsomest of border plants are to be reckoned the Oriental poppies. They have their drawbacks, it is true; their flowering season is rather short, they have an annoying tendency to tumble about especially when their big blossoms are soaked with rain, and their appearance when dying down is disreputable; but their glowing beauty more than makes amends for these defects.

Two particularly striking varieties are Goliath, which has immense scarlet flowers on 3ft. stems of unusual rigidity; and Crimson King, a splendid specimen of the bracteatum type with huge blood red flowers surrounded by green leafy bracts. It is of even sturdier habit than Goliath. Mogul is another fine deep scarlet poppy; while a comparatively recent and very showy introduction is the orange red Lord Lambourne which has delicately crimped petals. Crimped Beauty has flowers of a similar kind, as its name implies, but in colour it is pale salmon pink, and its height does not exceed 2½ft. The popular Mrs. Perry is a slightly brighter shade of salmon; Cerise Beauty is salmon flushed with cerise; Rose Queen is rosy pink just tinged with lavender; and Mrs. H. C. Stobart is almost true rose. All these are charming in colour, but they must not be placed near the red varieties unless separated from them by an ample screen of plants with either white flowers or grey or blue-grey foliage. The peculiar colour of Mahony—something between mahogany and maroon, with a dash of purple—is not to everybody's taste, but it goes well with the orange red of such poppies as William of Orange and Orange Glow and the paler shade of the dwarf Princess Ena. The white Oriental poppies are rarely very pure in tint; their petals, which in most instances are rather thin and papery, being more or less flushed with pink. Perry's White, however, which has conspicuous crimson blotches at the base of the petals, is a very fine variety.

On the whole, the best way of supporting these heavy poppies is to put stout pieces of pea-sticks not less than 3ft. tall among the young growth, driving them firmly into the ground, and, as the plants increase in height, to weave a sort of lattice-work of string between them. Bamboos may be substituted for what the West Country folk call "sticking-wood," but the latter is best. Oriental poppies can be cut half down without hurting them as soon as they have done flowering, and if, as has been previously suggested in THE GARDEN, clumps of Gypsophila paniculata or Kokejeka are grown behind them, the plumy sprays can be coaxed forward so as to veil their ugly remains. Furthermore, the dwarfer varieties of Phlox decussata may be planted in front of them to act as a further screen. The big poppies seed freely, but, unfortunately, only a small percentage of the flowers come true, the majority reverting to the old light orange red type with comparatively small flowers.

PERRY'S WHITE, A STRIKING ORIENTAL POPPY, WITH LARGE SATINY WHITE BLOOMS.

MUNSTEAD CREAM PINK, ONE OF THE DOUBLE PEONY-FLOWERED ANNUAL POPPIES, IS WELL ADAPTED FOR SHRUBBERIES.

No other perennial poppy rivals P. orientale in size and gorgeousnese; but some of the smaller kinds are admirable for the front of the border. Among these is P. pilosum, which grows from 1½ft. to 2ft. high and bears on slender stems flowers of a colour that has been described by different authorities as reddish buff, chamois and salmon, but which in fact is nearer orange than anything else. There is, however, a hybrid strain, P. pilosum × P. orientale, which varies in shade. The charms of the Iceland poppy, P. nudicaule, are familiar to all, but there is a fine orange variety, called Thibet (one of the late Mr. Farrer's introductions) which is less well known; its height is about 18ins., and it is said to be a true perennial, unlike the poppies of the ordinary nudicaule type, which, nominally perennials, are best treated as annuals. Other good varieties of P. nudicaule are to be found in the tall Harkness strain and the Coonara; the latter, which originated in New Zealand, has flowers of pretty pink and rose shades.

Equally suitable for border or rock garden is the Welsh poppy (Meconopsis cambrica), which, in its several forms—yellow, orange, double or single—is as pretty as it is hardy.

Meconopsis Wallichii, the blue Himalayan poppy, is a most beautiful plant for a moist peaty border, but it is useless to attempt to grow it in a hot dry soil full of lime.

Of the annual poppies the most effective in the border are the peony-flowered, which are 3ft. in height and have very large double blooms. Among the best varieties are Cardinal, scarlet with fringed petals; Nubian Prince, maroon red; Munstead Cream Pink; and Barr's White Colossal; but a packet of mixed seed will give excellent results. It is almost superfluous to say anything of the Shirley poppies, so widely appreciated are these dainty flowers in their delicate shades of pink, rose, yellow, orange and white. Sutton's strain of double Shirleys is scarcely so well known, but the colours equal those of the single type and they are better for cutting, although, like the rest of the poppy tribe, they are not long-lived in water.

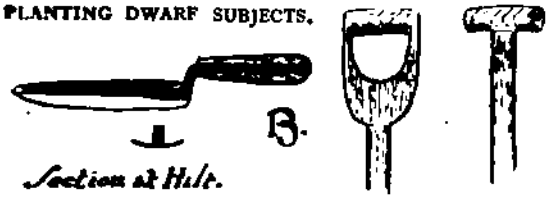
THE AMATEUR AND HIS TOOLS

I.—TOOLS FOR DIGGING AND CULTIVATING.

THE "garden tools" we see so prominently displayed in the ironmongers' windows at this season may be divided into three classes: those made for sale rather than for use; those valuable intrinsically but not recommendable for the amateur; and good serviceable tools of which the garden lover, whether amateur or professional, will never regret the purchase.

The very foundation of good gardening is proper spade digging; and the laboriousness

TROWELS OF DIFFERENT SIZES ARE USEFUL FOR PLANTING DWARF SUBJECTS.



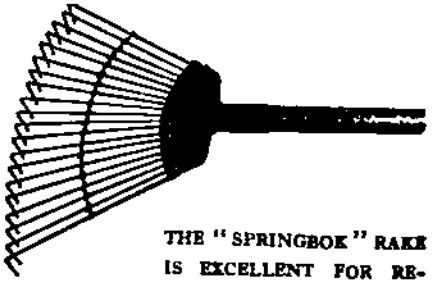
of the task may be appreciably lightened by selecting a suitable tool and by keeping it in first-rate order. When one thinks of the number of times in a single hour one has, when digging, to lift the earth-laden "pan" of the spade, the importance of balance and lightness of construction is easily appreciated. Professional gardeners who really know their work seldom use a spade larger than No. 1 size, of which the pan usually measures 11½ins. by 7ins. The amateur, especially the amateur who gardens on a stiff soil, would often do better to use a size O, which measures half an inch less each way. Then, one may save considerable weight and secure a better cutting edge by employing one of the "Neverbend" tools, which are made from the finest Sheffield saw-steel and are practically indestructible. Spades are made in many shapes to suit different markets; but those who garden for pleasure cannot go wrong if they buy the so-called "London pattern" with—it almost goes without saying—a D handle.

Many lady amateurs rely upon the "mere male" to do their rough digging; and most of the tools sold as ladies' spades are, in fact, quite useless for straightforward digging. The lady who is really anxious to do this foundation work herself cannot do better than get a standard size OO "Neverbend."

From the spade one naturally turns to the fork, a useful, even essential, tool, but one which in some gardens is used for tasks for which it is ill fitted. The legitimate functions of the fork are to break down ground already dug; to lift—or assist in lifting—shrubs and plants; to raise root and other vegetable crops; to stir or prick over the surfaces of beds and borders; and, in double-digging or trenching, to break up hard and possibly stony ground for the shovel or spade. For breaking down roughly dug ground and for pricking over beds, any good fork, even one with considerably worn-down tines, will answer perfectly. For trenching, especially in unbroken soil, a stout-tined fork with the handle steel-strapped right up to the D, and sold as a trenching fork, should be employed. To use an ordinary light fork for the purpose is merely to spoil an otherwise good tool. A trenching fork is, however, of little or no service for ordinary garden work.

For the lifting of crops and the other purposes for which a garden fork should properly be used, a broad-tined fork with a good "lift," and usually sold as a potato fork (see figure), is the most serviceable. Such a tool may be obtained in many good makes and at various prices, but the amateur cannot and must not expect to get for 3s. or 3s. 6d. a tool of the class of those for which he is asked half a guinea or more. The difference is soon apparent, both in balance and in wear. Yet the amateur with a very small and not very stony garden plot, who is prepared to restrict the use of his fork to the jobs for which it is intended, may manage quite well with a comparatively cheap tool. For those with larger gardens and for others who will go to the initial outlay to buy a really good tool, "Neverbend" saw-steel forks can be confidently recommended. These are well balanced, light in weight and wear evenly. And, above all, it is impossible to get distorted tines, either by reason of a stone jamming between them or from other causes. The tines *will* bend when sufficiently "provoked," but to remove the obstacle or the pressure is to find the fork perfect as before. This spring quality, however, does not extend to the languet; and care should be taken with *any* fork, unless perhaps a "trencher," not to use it as a lever when attempting to lift large shrubs etc., which still have unsevered root connections. An excellent fork and one which is hammer forged all in one piece—tines and straps—is the "Dreadnought," made at Wigan. This fork is made entirely from the very best quality solid bar steel without any weld whatever. The advantage of this is that it gives the fork far greater strength, for in the ordinary way the straps of a fork are welded on to the prongs and there is a danger of a fracture at the junction. For the use of ladies a fair-sized border fork is available, though most ladies can, on light or medium loams, use without undue fatigue the standard four-tined potato fork, 8ins. across and with, when new, 11½in. tines. The border fork is similar in construction to the potato fork, but made in smaller sizes.

SMALL HAND FORKS.



THE "SPRINGBOK" RAKE IS EXCELLENT FOR REMOVING MOSS FROM LAWNS.

For small planting, weeding and titivating beds the small hand-fork is invaluable. It should be of the shape shown at A on the figure, *not* with twisted tines as shown at B, this pattern being unsatisfactory in use. The same tool, but with an ash handle 3½ft. long, is particularly useful and helps to take a good deal of the backache out of gardening. See that both patterns are made of really good steel and have proper solid-turned sockets. The caution is necessary because quantities of these small forks—and trowels to match—are made (and sold) which are no better than painted sheet-iron. It has been suggested that the Legislature might well intervene to make the sale of such useless tools illegal.

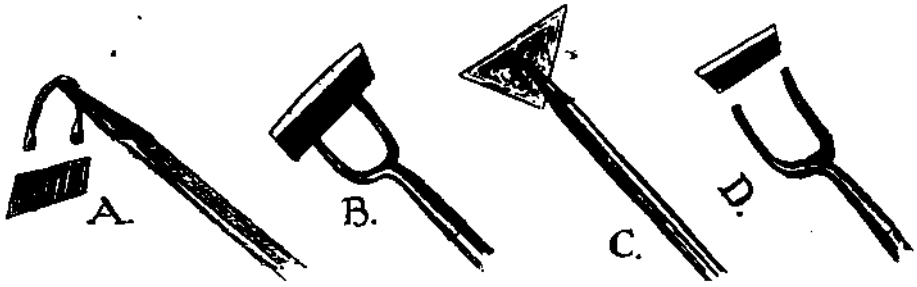
The hand-fork's mate—the trowel—is really a little one-hand spade, and the best shape for it is, as shown at A in the figure. This shape, however, is by no means easy to procure, trowels with a semicircular section finding favour with most makers. Such a tool should, none the less, be sought for, and is well worth the 3s. or 3s. 6d. asked for it. Tools of this pattern can be procured, if nowhere else, from a firm of ironmongers of Guildford. The little fern-trowel shown at B is most useful to the rock gardener and also for the amateur plant-collector to take with him on his rambles.

The average amateur is over-partial to the rake; yet it is an essential tool and one which needs to be of good quality. A rake

THE NEW SHOULDER HOE SAVES TIME AND LABOUR.

Digitized by Google

with a head about 16ins. across and with the teeth 1½ins. apart is a very useful, though seldom seen, garden tool. Rather a newcomer in this field is the well named "Springbok"



A BATTERY OF USEFUL GARDEN HOES.

rake, a moderately priced, unorthodox-looking tool which may best be described as a garden version of the well known "Parmentier" grass-harrow. *Facile princeps* for removing moss from and aerating the surface of garden lawns, it is also useful in many other directions.

Of hoes and other cultivating tools the name is legion. The three most useful types of hand-hoe are shown in the figure. These are the chop-hoe frame (A), to which blades can be fitted of various widths; the substantial Dutch or push hoe (B); and (C) the triangular hoe (for drawing seed drills, etc.), to which new blades can be fitted when necessary. For those who favour the Dutch type and use it very largely, a frame made as at D in the figure will take the ordinary hoe blades. In my experience, however, one has to get such a frame made by the local blacksmith.

A very useful aerating and weed-killing cultivator is the "Buco," made both with five tines and a long handle for border, shrubbery and kitchen garden; and with three tines and a short handle, for work among closer planting.

Where considerable spaces are devoted to one crop, there are many good and suitable wheel hoes and cultivators, of which the 'Planet Junior" tools may be taken as typical. These excellent little implements may be arranged to suit any width of row, and either to hoe, earth up or draw soil away from the rows, scuffle or break to a tilth, also for spacing drills.

Another simple and attractive "cultivator by wholesale" is the even newer "Shoulder-hoe," of which the main handle rests on the shoulder, while the work is done by drawing the cross-handles towards one and progressing backwards. It is claimed for this that it will, with less labour, do from six to eight times as much work in a given period as the ordinary chop-hoe—and do it better. This, again, will both hoe and cultivate, and is a most useful tool to possess where any considerable amount of ground is devoted to one crop, or where several crops are, for ease of cultivation, spaced at equal distances between the rows. It takes little space to store, and may quite well be used in the shrubbery and mixed border, as well as in the kitchen garden.

MIDLANDER.

WHAT OUR READERS SAY

AN ATTRACTIVE EDGING PLANT.

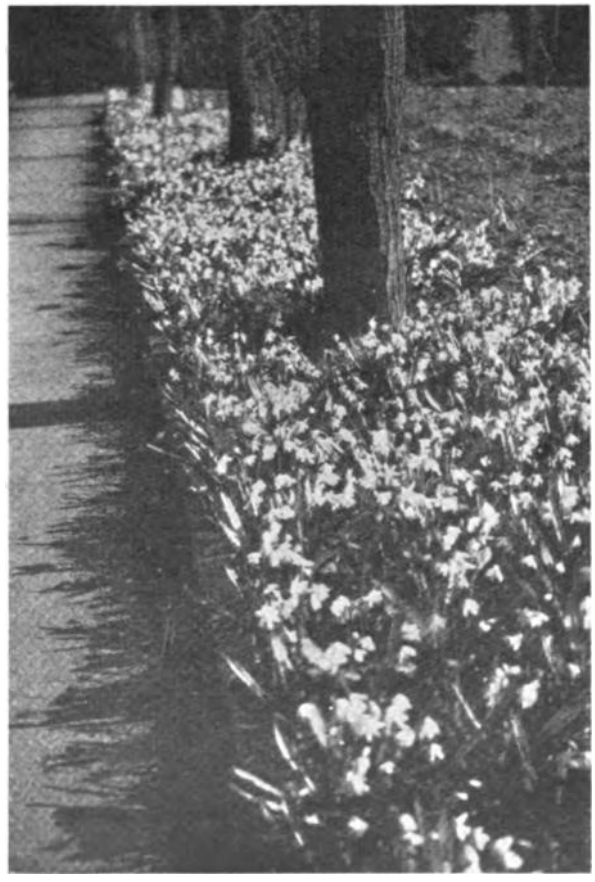
SIR,—I think the enclosed illustration of an edging of Scilla sibirica may be of interest to many of your readers. This is a spring flower which every amateur should grow. It comes up year after year without any fresh planting. It is of a bright blue shade and is about 9ins. high, and makes a fine splash of delicate colour.—MISS SMITH, *Eccleshall, Sheffield.*

GENTIANA ACAULIS.

SIR,—Referring to your correspondent's note on Gentiana acaulis, I wish all your readers who desire to grow that beautiful gem could meet with the success that I am enjoying. I have a bed about 3ft. by 5ft. on which I counted over 200 buds and fully expanded flowers the other day; it is wonderful to see how eager they seem to make a show, some plants only 6ins. across have ten buds and flowers on, these plants have kept on flowering all through last year. It is seldom there is not one or two in flower. They are planted in a bed facing east, with a gooseberry and small yew shielding them from the midday sun. The soil is a somewhat heavy loam. They certainly do not like coddling. I am about one mile from the river Dee.—S. MARTINS, *Cheshire.*

DYING BACK OF ROSE GOLDEN EMBLEM.

SIR,—Regarding the dying back in winter of Rose Golden Emblem. I, as a Kincardineshire reader, have had a few years' experience of this rose, therefo e I have had ample and annual proof of this fault with it, as well as many others in these parts. St. Mungo in his appeal to Scottish readers in THE GARDEN of April 23rd, page 271, in support of his statement (of the dying back habit of Golden Emblem), will have little difficulty in finding many to back it, at least in these northern parts. Two different gentlemen from English counties were surprised to see it flower so well here and told me they had discarded it on account of it always dying back. Of a few yellow roses we grow here Golden Emblem gives by far the best, largest and shapeliest blooms. The light soil with plenty of attention to feeding appearing to suit it. During summer it grows vigorously, making strong and magnificent growths. The later made growths are never sufficiently ripened to stand our cold winters and the tops, at least, succumb to the first hard frost, in some cases almost cut to the ground. Those with the tops only blackened usually decay well down the stem before the spring. We have had none actually die and the remaining buds always come away strongly and flower well. I should very much like to have asked the gentleman who advocated the mulching of roses (at the Hamilton meeting that St. Mungo refers to), what possible benefit (apart from manurial), or protection, mulching would be to preserve the stems of roses, as the plants in question would derive no protective help in the least. I consider it only softens and blanches the stems thus covered for the winter months and results in injury when they are exposed in late spring.—WM. GRANT, *Kincardineshire.*



SCILLA SIBIRICA, WITH ITS BRIGHT BLUE FLOWERS, MAKES AN ATTRACTIVE EDGING PLANT.

CYNOGLOSSUM AMABILE.

SIR,—I have been much interested in the notes on Cynoglossom amabile, which have appeared in recent issues of THE GARDEN. W. Linders Lea commends it as a border plant, but in my opinion such a position would not give the plants full justice. In large beds or masses is where they show their beauty to best advantage. When the plants come into flower the beds present a charming cloud of blue forget-me-not like flowers, light and graceful. The flowering period continues throughout the summer until frost cuts it down in late autumn. The plants grow here from 15ins. to 18ins. in height and beds in grass are better for having an edging of a dwarf plant. The raising of young plants presents little difficulty, as this borage is most accommodating in that respect. If it is desired to have large specimen plants to bed out, then a sowing should be made in early August on a sheltered border outdoors.

The seedlings, when large enough, may be transferred to cutting boxes of fairly good light soil, given a good watering, placed in a cold frame and kept rather close for a few days. When the plants are established,

Digitized by Google

full ventilation should be always maintained, except during rain. If severe frost comes the frames should be closed and mats laid on. Without all the foregoing trouble good plants can be raised by sowing near the end of February or beginning of March in slight heat, if such be available. If seedlings of this sowing be attended in to the way of pricking them into other boxes, as required, and keeping them growing, they will be fine plants to put into beds by the end of May and will give a fine display of bloom. This is the method I usually follow, much less labour being entailed. They may be planted out about 15ins. apart each way without the slightest fear of not filling up the space. If any of these methods be followed in the raising of the seeds, it will be readily admitted that lifting and keeping old plants in frames throughout the winter is not worth the trouble, apart from the unsightly size they would become. I have never found old plants able to survive a winter here. If the beds which the plants occupied during the summer be not disturbed and are not dug during winter, when the ground is examined in March, hundreds of seedlings will be found pushing their way through the soil. A spruce branch or two laid on the beds will much facilitate the earlier growth of these young plants, which can be lifted, if required, the boxes placed in a cold frame and treated as stated for other seedlings. I have found Cynoglossum amabile a most accommodating plant, neither "dorty" or delicate of constitution, giving a splendid display of bloom all summer and of neat habit. I think it a most desirable plant for the amateur who has not much artificial heat at his command, and, like W. Linders Lea, presume it will be also more widely grown by gardeners as it becomes better known. —G. WILLIAMS, *Scotland.*

"THE GARDEN" PHOTOGRAPHIC COMPETITION

THIS WEEK'S GUINEA PHOTOGRAPH.

Sent in by MR. C. NIPPARD, *Bournemouth.*

This photograph represents a section of a conservatory which is circular in design. The idea has been to grow plants whose colours when combined furnish a pleasant colour scheme. The one in question is pink and white, carried out with Hyacinths Madame Kruger, Ornament Rose and Grandeur à Merveille, spikes of the latter measuring ten inches from the top to the bottom.

Cyclamen Silver Salmon and Primula obconica Giant White are arranged in small groups, this giving a more charming effect than when the plants are mixed indiscriminately. Primula obconica is a most valuable plant for the cool house, as from an April sowing plants will bloom continuously from December to June. This photograph was taken on April 11th of this year.

SPRING GREENHOUSE FLOWERS IN PINK AND WHITE.

On either side of the central lawn of this London garden are flower borders. On the shady side is a comparatively narrow border, while on the sunny side of the garden there are wide herbaceous borders divided by a path. Espalier fruit trees are grown against the walls, and in between these, standard flowering cherries, crabs, laburnums and lilacs are planted. At the end of the garden there is a small raised shrub border, which is planted with berberis, philadelphus, spiræas, flowering currants, deutzias, escallonias, etc., and in front of this is a rockery bank. The bed in the foreground is edged with nepeta and filled with mixed gladioli.—E. MILLER, *Wandsworth Common.* Award of 5s.

The pergola seen in this photograph was erected in 1925, *and against it the rambler roses American Pillar, Dorothy Perkins, Excelsa, Emily Gray and Hiawatha have been planted. It forms an effective screen and makes the garden more secluded. Lupins, delphiniums, irises and Canterbury bells do particularly well in the borders surrounding the lawn, and these plants made bold masses of colour during July, when this photograph was taken. Perennials of all kinds are also planted in the borders, and in the springtime daffodils, primroses, snowdrops and crocuses fill all the odd gaps. It makes a charming garden in a small space, and is one which can be carried out with a minimum of labour.*—D. R. BROOKS, *Stockport.* Award of 5s.

THE FRUIT AND KITCHEN GARDEN

May in the Fruit Garden.

Reminders.

THINNING FRUITS.—Partial thinning of fruits should commence this month by the removal of the badly placed and smallest specimens. Apricots may be thinned to two to three fruits per square foot. The operation should be performed at several times to avoid too great a check to the tree.

Disbudding.—The buds on the fruiting shoots of the peach, nectarine, Morello cherry, with the exception of the terminal bud and one or two basal buds, should be rubbed out except where a growth is required for furnishing the tree. The regulation of shoots on the apple, pear, plum, cherry and apricot should commence. Do a few shoots at a time.

Apricot—Pinch growths not required for extension to a few buds.

Morello Cherries.—Keep a look out for the appearance of black fly, and at the first sign dust the trees with tobacco or hellebore powder. All wall trees should be carefully inspected for the appearance of pests, old leaves should be removed and means taken to combat the attacks of aphis, etc., on its appearance. "Abol" insecticide at the given strength may be used against aphis. Mildew may be combated by dusting with flowers of sulphur.

Strawberries.—Hoe in between the rows and get straw ready for bedding between the plants. Some of the early varieties may start to flower, and it is advisable to have some light material handy to protect them at night in case of frost.

Gooseberries.—A mulching of rich manure should be placed round the bushes. Superfluous shoots should be removed from the centre of the bush to let in light and air. The fruit can be thinned and the thinnings used for pies, etc. Watch for the appearance of caterpillars on the bushes and use "Katakilla" or some other suitable insecticide as a remedy. If arsenate of lead is used, great care must be taken to wash thoroughly all berries before using, as arsenate is highly poisonous.

Raspberries.—Those which have not received a mulch of manure earlier will greatly benefit from waterings with dilute liquid manure and covering the roots with grass cuttings. Growths which come up in excess of those required for next year's fruiting canes should be removed.

Wall Trees.—Wall trees which are dry should receive thorough waterings.

Grease Bands.—Remove and burn.

Coverings which were placed over trees to protect the blossoms from frost should now be removed, as the blossoming period is over and it is necessary that the tree should get all the light and air possible.—D.

Vegetable Notes for Northern Gardens.

Work for the Month.

DURING May, make a practice of hoeing as often as possible. Remember, weeds are easily killed while small, and by hoeing one prevents the surface soil getting hard and drying out so fast. This is the month for sowing carrots, beet and beans. The former may be grown on many kinds of land, deep sandy loam being the best for intermediate and long types and the early stump-rooted varieties for heavy land. The carrot fly can be kept off to a certain extent by mixing a little paraffin with dry earth or sand and sowing along the sides of the plants; but I much prefer a preparation called "Terrafumite." I have tried it for several years without a failure. It requires forking in a few days before the seed is sown, and, after the plants can be seen in the rows, a little sprinkled along the rows and worked in with a hoe. Sow the seed in rows a foot apart and thin out as soon as the plants are big enough to handle. I find that it pays to thin out to 4ins. apart and to use every other seedling when large enough for cooking purposes. A little "Terrafumite" used about the end of the first week in July will keep the rest of the plants free from fly and grub.

Beet can be sown in rows 9ins. apart, and thinned out early to 4ins., later taking out every other plant. Sown early in May, excellent roots can be had for use during the summer and autumn; but sow a few rows at the end of the month or even the middle of June to keep during the winter. About the middle of the month sow dwarf beans, allowing a distance of 18ins. between the rows. A good way is to dibble a hole about 3ins. deep and put two seeds to a hole, which should be about 15ins. apart. Later, if both come up, destroy one. Make a practice of sowing a pinch of lettuce seed every fortnight. If any seedlings are transplanted select a spot rather shady and give plenty of water. Radishes may easily be grown in most gardens, but they, too, like a moist and rather shady place; otherwise, if sown out in the open allotment or sunny garden, they quickly go "woody."—F. C. K.

TYPES OF SEEDLING TOMATOES.
The one on the left is a normal plant, and should be potted; the one on the right should de discarded.

Earthing up and Feeding Early Potatoes.

THE earthing up of the first crop potatoes in good time serves two useful purposes. The additional soil helps to guard the tops from late frosts and induces early swelling of the young tubers. If potatoes are not earthed up at all, the crop is rarely as heavy as in the case of earthed up ones. Furthermore, the tubers are smaller. The best manure for the potatoes is good, well rotted farmyard manure that has been stored in an open shelter and not exposed to the rains; it should be mixed with the soil before, or at planting time. It is too late now. A quick-acting stimulant may be applied now, however, with very beneficial results. Sulphate of ammonia, at the rate of 2lb. per 40 sq. yds., should be applied very evenly on the soil immediately between the plants in the rows and not between the rows themselves, just prior to the earthing. The soil will then cover in the stimulant and the roots will quickly benefit. In the case of all early potatoes and in all soils except those that are very sandy, the soil drawn up should form a ridge sharp at the top, as the ground will contain sufficient moisture. If the work of earthing is put off till late, the young tubers or their runners are liable to be cut off or unduly exposed when the soil is moved.—HANTS.

Selecting Tomato Plants.

A Point Which Every Amateur Should Note.

IN every batch of tomatoes raised from seed two types of plant appear. These types are represented in the accompanying illustration. The one on the left is a normal plant, the one on the right a rogue. The rogue plant can be readily distinguished from the normal plant by its shorter internodes and general telescoped appearance. These rogues should not be planted, as the first flower truss usually aborts and the second truss bears little or no fruit, thus reducing the possible crop considerably. These rogues can be picked out when three to four leaves have formed. In appearance they are quite healthy and stocky plants, and ones which might easily be planted if one were unaware of the existence of such rogues, but they should be discarded.—H. B.

The Magpie Moth.

ONE of the most destructive pests with which the grower of red or white currants and gooseberries has to deal is the caterpillar of the magpie moth. It is the habit of the larvæ of this moth to remain in a dormant state during the winter either among the branches of the bushes or in the soil below. With the arrival of the spring the caterpillars become active once more and are on the bushes as soon as the new foliage begins to expand. Their appetite is enormous, and it is not at all an uncommon thing for the foliage to be devoured to such an extent that a bush is practically without any leaves. The fruits are not attacked in any way, but no bush can produce a good crop without a healthy supply of leaves, and the result of an attack by the magpie caterpillar, and much more so if this happens each spring, is disastrous.

Get some arsenate of lead or Paris green and dissolve 1 oz. in 3 or 4 gallons of water, preferably lime water. Syringe the bushes with this twice while the foliage is in a young state. In May the caterpillars will be of good size, and any pests that remain should be hand-picked. A good plan is to spread sheets of newspaper under the bushes and then allow a quiet interval. Now approach and give each bush a sudden and rather violent shake. The caterpillars are so startled that they release their hold and fall on to the paper. If this treatment is repeated two or three times, large captures of the grubs may be made. As soon as the caterpillars are fully fed, they become dormant and at the end of May turn into pupæ. These are to be seen hanging from the branches, and they are black banded with orange. These should be collected and destroyed to prevent the emerging of the moths, which will take place in July.—K.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

GIVEN freedom from low temperatures and wet weather, the amateur should now be in a position to make rapid progress in the various departments of garden work. As is not uncommon in our northern climes, the prospects of a seasonable spring, based on the genial conditions experienced in March did not materialise in April, which, in many parts of the country, will be remembered for its broken weather and excess of moisture, which curtailed outside operations. In the more favoured districts, however, vegetation is well advanced as the results of risks undertaken by individual horticulturists. In a manse garden at Girvan, where I spent a brief Easter holiday, chrysanthemums were bedded out and the foliage of the early crop of Epicure potatoes was well above the surface of the ground. Pear and plum trees were rich with blossom and hardy veronicas, exposed to the sea breezes, were showing their lilac or blue flowers. Even in the fields the potato crops were in process of grubbing preparatory to weeding. Such experiences, however, are the exception rather than the rule.

Where there is a small bit of ground to spare, it may be put to good use by sowing a small quantity of sweet williams, wallflower, Canterbury bells, aquilegia or other popular flowers grown as biennials. To the novice it may seem premature, if not incredible to sow seeds of plants that are to furnish next season's display when this year's bloom is only commencing, but the long period of growth required by these subjects necessitates May sowing. The soil should first be forked over and thoroughly raked so as to remove stones, weeds and lumpy portions of earth and put the surface in a fine tilth. After drawing out shallow drills, distribute the seed thinly and cover lightly. Strange to say there is a sharp diversity of opinion among gardeners regarding subsequent treatment, and as some growers favour a loose surface, while others prefer that it should be made firm, the reader will require to use his own discretion. When the seedlings are large enough to handle, they should be pricked out into another bed, if robust, bushy plants are required for planting in their permanent quarters in autumn.

Sweet peas that were planted out in April are now making growth, which will become more rapid as the young roots get down to the food provided in the lower spit of the trench. From now onward tying becomes a constant job, but no stimulant in the form of liquid or artificial manures is necessary until the plants are coming into flower. Should the seedlings be slow in recovering from the check, which usually follows their transference to the open ground, their progress may be accelerated by occasional applications of manure water reduced to the colour of weak tea. If the soil was generously manured when the trench was made in winter, the supply of food should be sufficient for the nourishment of the root system throughout the season, but if a mild stimulant is considered advisable, especially during spells of warm, dry weather, there is no better or cheaper treatment than sooty water, which also has a beneficial effect on the colour of the flowers. A good plan which finds favour with expert growers is to apply plain and sooty water alternately during the period of bloom. Keep a sharp look-out for any indication of wire worms, which are responsible for the loss of plants and as a precautionary measure an endeavour should be made to trap them by placing pieces of potato or turnip in the soil at intervals along each side of the row. Birds are sometimes troublesome as they have a natural liking for the newly formed buds. The tits are, perhaps, the greatest enemy among the winged tribe and while it is impossible to control their movements, strands of black thread fixed at irregular intervals helps to keep the marauders away.

The economical value of a frame as an adjunct to the garden is not sufficiently appreciated by occupants of the housing schemes, many of whom are engaged in the raising of flowers and vegetables for the first time. By relying on a nurseryman to provide the necessary plants they miss the pleasure experienced by the man who raises his own seedlings and increases his stocks by cuttings at the sole cost of his labour. From whatever standpoint the proposition is considered a frame is a profitable investment, although its purchase involves a larger expenditure than was necessary in pre-war days. Much of the initial outlay, however, may be obviated, for there is nothing to hinder a handy man from constructing a frame in his spare time. The construction of the woodwork is simple and the sashes, which are made to standardised sizes, can be bought at a moderate price. The latter are now largely used by trade growers and while they may not serve all the purposes of a frame, they afford protection to plants during spells of frost and wet weather. They are usually supported by four wooden standards, and it is a point in their favour that they can be raised or lowered to suit the height of the crops to be moved from one bed to another. Sashes are also useful for protecting fruit on wall trees and accelerating the production of early vegetables, in fact they can be utilised in so many different ways that no small garden should be without them.

Early flowering single chrysanthemums are becoming more popular every year and as the flowers in their cut state make a pretty table decoration, a trial may be made with the following small collection, which is suitable for outdoor culture: Lacewing, shell pink (Aug.); Sunstar, chestnut and gold (Aug.); Shrapnel, orange terra-cotta (Aug.); Glorious, deep crimson (Sept.); Dolly Thorpe, salmon apricot (Aug.); Supreme, deep yellow (Sept.).

Six varieties that are representative of the best for greenhouse cultivation: Phyllis Cooper, orange gold; Mollie Godfrey, deep pink; Catriona, old rose; Reginald Godfrey, chestnut red; Myra, lavender suffused over white ground; Absolute, orange amber with yellow zone.

ST. MUNGO.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Summer Treatment of Ericas.

I have a bed of fifteen varieties of heaths doing very successfully in a rather exposed garden on dry sandy soil in summer, with cold frosts in winter. In early spring seedling (tall) larkspurs are inter-planted among them, which, while allowing early bloomers to be seen to advantage, provide, later, necessary shade from hot summer sun and winds, when such shelter is necessary—the annuals then being beautiful with bloom. The heaths put on new wood apace and occasional hosings with rain water keep both varieties happy on the light soil. As autumn advances and more exposure is needed, the spent annuals are pulled out, exposing to view later flowering heaths. Sufficient protection from winter frosts is given by some light scrub and scrim. This treatment allows of a large number of varieties to grow in an otherwise impossible locality.—M. E. P.

A Hint on Manuring Roses.

Liquid manure prepared from half a peck of fowl droppings and a similar quantity of soot, placed in a sack or bag and immersed for a week in a barrel or cask of water. Applied at the rate of a gallon each tree once a week, it will be of great benefit. Should the weather be dry, give each tree a good soaking of clear water first, before applying the liquid manure.—G. B.

Young Cabbage Plants.

Many amateur gardeners and allotment holders purchase their young cabbage plants, especially at this season of the year. Unless precautions have been taken with the lifting of these plants and subsequent care taken to avoid root dryness, much damage is done to the root system. I find it a good plan to treat purchased cabbage plants as follows: Dig a hole in the garden, and in this make a thick puddle, insert the roots in this puddle, covering them with more soil and leave them protected from strong sunshine for a day or two. This encourages new roots to the extent that the plants suffer little or no check when planted in their permanent quarters.—J. H.

A Pseudo Cement Path.

At country houses, where acetylene gas is in use, the residue, when dry, may be turned to good account for path making. It should be used at the rate of one part residue to three parts finely sifted ashes, turned two or three times in a dry state and then puddled up exactly as if the mixture were cement and sand. This should be spread over the path (preferably on a layer of cinders), to a depth of at least 2ins. If the weather is frosty, the path should be protected by means of old sacks at night, until set. When almost set it is a good plan to roll it with a light roller. This path is practically equal to cement.—W. L.

How to Get Rid of Moles.

Moles are often a great pest in gardens and I was for several years much bothered by their runs in my flower borders, until I tried the following experiment, which has completely sent them away. On seeing a fresh run I immediately took a bamboo cane and made a hole into the centre of the run, then I dropped into the hole two or three moth balls (naphthaline) and re-covered with soil, which drove away the moles.—H. W. G.

Growing Tall Nasturtiums.

Where room permits a most effective display of tall nasturtiums is obtained by sowing the seeds along the four sides of a large square, or on the circumference of a circle. Pea sticks, sufficiently supple, are then placed within the sown lines, interlaced and bent inwards so as to form a dome. The vines climbing this support soon become a mass of foliage and flowers, which completely hide the sticks. This idea occurred to me when needing to deal quickly with an ugly piece of waste ground. The result was so satisfying that I have never lost an opportunity since of growing nasturtiums in this way.—C. M.

GREENHOUSE NOTES

How to Succeed with Petunias in Pots.

THE double-flowered petunia forms a splendid pot plant and is most useful as a flowering subject in rather sunny greenhouses, glass porches, windows and balconies. It makes a good companion plant to the fuchsia and may be associated with the zonal pelargonium. While the single-flowered petunias are easily raised from seeds, the double ones must be propagated from cuttings. The present is a good time for the inexperienced cultivator to start with young, well rooted plants. Such may be bought from firms advertising in THE GARDEN. Cold frame treatment should be given from May to mid-June, open-air from the latter date to mid-August, then greenhouse treatment for exhibition purposes; or cold frame treatment throughout for July and early August shows. Of course, the plants may be retained under glass all through the summer when the object is the decoration of such structures. For all stages a light, rich and porous soil is the best in which to grow healthy plants. Their roots are fine—rather fibrous—and porosity of soil is essential. The rooting medium must also be a firm one; then, if the plants are kept in a congenial atmosphere, they will retain the fine leaves down to the rims of the pots. Feeding should commence directly the flower buds form—those buds that are to be allowed to develop into blooms. The young plants are now about 6ins. high; the tips should be pinched off, then side shoots will form; when these are 1in. long repot the plants. In due course take the tips of the side shoots, and finally repot the plants; allow all shoots, from this stage, to grow on and develop flowers. The plants will now be bushy and continue to bloom until frosty weather or late autumn time comes, as the petunia will not withstand frost outside nor grow well under glass after mid-October. Cuttings should be rooted in August and early in March.—G. G.

Care of Pot Plants.

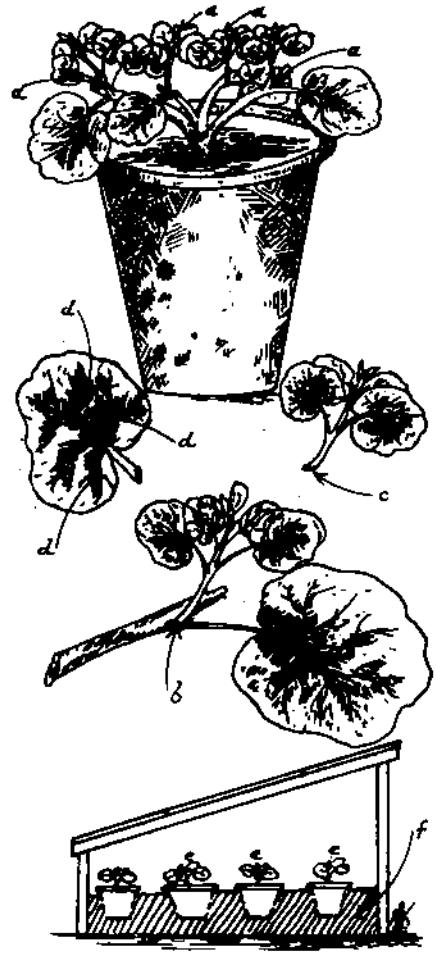
A COMMON cause of failure with these is indiscriminate watering, and especially is this the case with plants in windows. Some wait till signs of distress are apparent, while others go to the other extreme and give water at too frequent intervals. The aim should be to keep the soil sufficiently moist always, but no definite rule can be laid down as to when plants require water. The best guide, perhaps, is the weight of the pot when lifted. If the soil is becoming dry it will be light compared with its weight immediately after watering. A little practice in this direction will enable the inexperienced to become proficient in the art of watering in a short time. While all plants require to have the soil moistened throughout, special care is needed in regard to azaleas and similar plants, otherwise the compost, consisting mainly of peat, will shrink and the plants in consequence will be much distressed even if they do not collapse.

Ferns which have been grown in a humid atmosphere must be watered very carefully when placed in rooms, where the air is always dry; and a draughty position will almost certainly mean disaster with these. Even with less susceptible plants cold currents of air are always dangerous. Plants procured in small pots and grown on are most likely to be a success, as at that stage they quickly adapt themselves to their environment, and with care will remain in health for years. Established plants that have filled their pots with roots will benefit from stimulants during the growing season. There are several suitable fertilisers available, and if used in accordance with instructions supplied with them they will prove highly satisfactory. The points to bear in mind are: not to give too strong doses and to see that the soil is thoroughly moist before using them.

The value of soot water, especially for foliage plants, should not be overlooked. Plants of this class should be carefully sponged occasionally to remove dust from the leaves. It may be noted that the present is a suitable time for repotting window plants.—J. C.

Present Treatment of Begonia Gloire de Lorraine.

THIS winter-flowering begonia is a general favourite with amateurs who wish to have a good display of pink-coloured flowers in their warm greenhouses from October to Christmas. When the flowers begin to fade



soon after Christmas, the old plants should be most carefully dealt with as regards watering, as there is little active growth. Plants should be placed on shelves where the maximum amount of air can reach them; then damping of succulent stems is avoided considerably. As the sun gains in power its rays, coupled with the artificial heat in the structure, cause young shoots to grow from the axils of the leaves on the basal stems, and by the month of April many young shoots will be large enough to sever from the old stems and insert as cuttings in the same way as are zonal pelargonium cuttings. The soil suitable for the cuttings is one composed of good sweet loam three parts, one part peat or leaf-soil well rotted and one part coarse dry sand. The insides of the pots must be clean, and those ranging from 3½ins. to 6ins. in size can be used; of course, several cuttings should be inserted in each pot, the number according to size, but do not overcrowd. The shoots to select are similar to those shown at *a*, *a*, *a*, *a*. Take them off at *b* with a small heel attached as shown at *c*, they will then be ready for insertion. Leaves may be propagated, the stem inserted or the ribs notched on the underside as shown at *d*, *d*, *d*. In the case of the leaves they are pegged down on the sandy surface with the stalk end buried in the soil. Cuttings are inserted singly in small pots or a number round the sides as shown at *e*, *e*, *e*, and then the pots are plunged in coconut fibre, *f*, placed in a propagating frame, the latter being fixed over hot-water pipes if they are available Uniformity of moisture at the soil level and in the atmosphere and judicious shading are main points to observe.—GEORGE GARNER.

Spiræas After Forcing.

THERE is no gain whatever in keeping spiræas in pots after they have been forced into bloom and fulfilled their mission. They are never satisfactory for potting the following autumn, but should be given a place in the garden where, turned out of pots, they can be planted out and left for a couple of years. It is a mistake to leave them for long in pots or in a cold frame, where, not infrequently, they become dry and suffer for want of water. In May, at any rate, they should be given open-air quarters, providing them with a partly shaded position and soil in which some old manure or rough vegetable compost has been worked. Large crowns can be divided, as it is not the largest clumps which produce the most flowering spikes. In planting them out the top of the crowns should be just covered with soil and no more. Little attention will be needed for the first eighteen months beyond keeping the ground free from weeds. A half-shady border or spot is the best for herbaceous spiræas, as here they will have a chance of re-establishing themselves, but they ought not to be subject to "forcing" the succeeding year. Rest and recuperation is needful for them, as it is with other things brought into heat—rhubarb, for example.—W. L. L.

Shading the Greenhouse.

SOONER or later during May it becomes necessary to shade the greenhouse, not only to prevent too rapid drying up of pot plants, but also to prevent scorching sunshine from doing harm to plants, shoots and flowers It cannot be denied that permanent lath or similar blinds are best; these admit a diffused sunshine and, being capable of immediate removal, allow the grower to shade when and as much as desired. When an outside blind is not possible, inside blinds of light cloth or other material may occasionally be rigged up; they, too, will be erected at a short space from the glass. For the man who cannot attend his houses closely, permanent washes are best; and the man who has but a small house to look after cannot do better than procure a shilling tin of powder for making up the wash. Older washes were made from whitening and buttermilk, flour and milk, whitening and size (2 oz. per gallon, previously dissolved in a little hot water), white or green distemper and so on. Limewash may also be used, but it has a caustic action and may spoil the paintwork in time. Apply with a brush, stippling each stroke for neatness; apply on a warm dry day. Shade the front glass only of tomato houses; shade all the roof of fern houses; and shade other houses so as to deflect the direct rays of the sun when it is strong.—LANARKSHIRE.

UNIV. OF MICH.

THE

GARDEN

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2893 Saturday, May 14th, 1927 Price TWOPENCE

SWEET WILLIAMS have long been favourites in our gardens. They rank among the most beautiful of our hardy garden flowers, and are worthy of being grown in every garden, both large and small, throughout the country In recent years they have been greatly improved, not only in regard to the size of their flowers, but also in range of colouring, with the introduction of many fine new art shades The modern strains give plants carrying large and bold trusses of sweetly scented blooms in a wonderful variety of pink, cerise, scarlet and crimson shades In some cases, separate colours can be obtained true from seed. The flowers look well if massed in beds by themselves, or in clumps in the mixed border. Beyond a fairly good soil, the plant requires little attention. Seed can be sown in the open from now onwards and the seedlings transplanted in autumn or spring for flowering next year.

VOL. XCI.—No. 2893. MAY 14, 1927. PRICE TWOPENCE.

COLOUR VARIATION IN WALLFLOWERS

IT has been brought to our notice that this season wallflowers are showing an extraordinary variation in the colouring of the flowers. This is especially the case with the dark crimson and red varieties, where this stippling and streaking of the blooms have been so marked as to alter the whole appearance of the variety. This is a point of some importance, since, quite naturally, blame may be attached to the source of supply of the seed or plants purchased on assurance that it was a definite colour variety. It may be said at the outset that no blame attaches to the seedsmen in this connection. In trial grounds which have been visited the effect of this stippling is most marked where the plants are grown in the mass, even more so than in the case of many private gardens and many of our seedsmen are at present doing their utmost to discover the cause of the trouble and institute proper remedial measures. It certainly is most unfortunate where the garden display has been spoiled to any extent, when, for example, seeds of a certain dark-coloured variety have been purchased to blend with some other flower to produce a pleasant colour combination.

This streaking effect in the colour of the blooms is not by any means a new feature in the case of wallflowers. It has occurred in several instances in previous years, but this season it would seem to be more prevalent than usual in the majority of gardens. Its appearance this year is difficult to account for. There would appear to be many reasons involved and in all probability it will be found, when the matter is thoroughly investigated, that it is due to a combination of factors rather than to one isolated point. As far as the evidence goes to show at present it seems to be a fact that the alteration in the colour is in no way due to the seed. The stippling does not appear to be hereditary and will not be transmitted to the next generation. That is to say, that if seed is gathered from a flower showing streaking and sown, it will produce, given suitable conditions, plants with flowers of the normal colour of that variety. On the other hand, changes in the environmental conditions surrounding the plants undoubtedly seem to exert some influence on the alteration of the colour pigments which go to make up the flower colours. The position and situation of the plants, the soil and the weather, combined with the time of flowering, all appear to play some part in the production of the stippled effect. Plants growing in an exposed situation show it more than others growing in a sheltered position alongside a hedge or wall, where they are protected from frost and cold, drying winds. The presence or absence of lime in the soil also seems to affect variation to some extent. On the whole this is a point which requires further investigation, as it may be that the degree of lime present in the soil composition upsets the pigmentation by chemical alteration in the food material taken up by the plant. As is well known, the wallflower likes a little lime in the soil, but it may be that the plant can be treated too kindly in this direction. The weather this year has undoubtedly been responsible for a great deal. After a period of a week's rain there was a sudden check to almost perfect summer conditions, which dried out the soil suddenly, causing the surface to become hard and caked, with the result that there was no aeration. These conditions have continued up to the time of writing and have been accompanied by cold, drying winds and heavy frosts at night, which have not helped matters. All transplanted subjects have suffered badly through the fact that they have not been able to become thoroughly established before the onset of drought with these drying winds. The sudden change in the weather at a time when the flowers were forming and colour pigments being laid down may well account for this variation, although it is difficult to prove. As has already been indicated, it is probably not due to the action of any one of these factors, but rather to a combination which has led to this effect, which is so marked this season. It seems certain that it is not disease, nor is the trouble hereditary. It is purely physiological and shows the reaction of the plant to an association of unsuitable conditions, embracing weather, soil and situation. It is a matter for prompt and thorough investigation by any of our leading horticultural institutions engaged in similar problems and it is to be hoped that some further results may ensue from a critical and scientific examination which may prevent a recurrence of the trouble. In this way these institutions would be rendering a useful service to the seedsman and amateur gardener alike.

"The Garden" Photographic Competition.

ON page 317 of this week's issue will be found the photographs published in connection with our Photographic Competition. Readers' photographs will be published every week, and we urge all readers who are interested to send along photographs of their gardens during the summer months. Particulars should accompany all photographs so that the illustrations will prove more helpful to the majority of our readers. The rules governing the Competition will be found on page x.

This Week's Work

For Gardens in the South and Midlands.

Prune early-flowering shrubs when they have finished flowering.

Tie up all creepers and climbers.

Harden off all bedding plants and clear the beds of bulbs and other spring-flowering subjects.

Start to harden off dahlias and border chrysanthemums ready for planting out.

Mulch with well decayed strawy manure any newly planted shrubs.

Thin all seedlings in the flower or vegetable garden.

Prepare ponds and bogs for planting water lilies and bog plants.

Fill in gaps in the rockery with pot-grown specimens of late-flowering alpines.

This Week's Work

For Gardens in Scotland and the North.

Begin planting out half-hardy annuals.

Sow Shirley poppies, mignonette, eschscholtzias, etc., in the open where they are to flower.

Transplant chrysanthemums and bedding calceolarias.

If needed, prune lilac and flowering currants after bloom is over.

Syringe roses with a solution of soft soap and quassia extract.

Lavender cuttings strike easily now if taken with a "heel."

Every wasp killed in May means a nest less in autumn.

Cauliflower may still be planted in dull or showery weather.

Sow main crop carrots.

SOME BIENNIALS FOR PRESENT SOWING

ALTHOUGH the number of hardy biennials is not very large, the plants form an important class. It is, of course, the habit of these plants to flower the season following that in which the seed is sown and then, in most cases, the specimens die. That the biennials are valuable subjects is realised when we remember that wallflowers, Canterbury bells, sweet williams, foxgloves, etc., belong to this group. Biennials are easy to raise owing to the fact that the sowing of the seed may be made at almost any time from the spring until the late summer, just as happens to be most convenient. With one or two exceptions it is best to sow the seeds in a prepared border out of doors. Avoid a position where the soil is very rich, and never manure the ground before sowing. Rank-growing plants are not desirable, for these will not stand the winter so well as the tough, sturdy specimens which it should be the aim of the grower to secure. Dig the seed bed over and then tread rather firmly, completing the process by raking up the surface finely. With a hoe draw shallow drills 1in. deep, 2ins. wide and 1ft. apart. In these scatter the seed thinly and draw the fine soil into the drills again. Label each drill with the name of the plant and so avoid the annoyance later on of not knowing quite what you have grown. In due course the seedlings, which may require a thinning, will become large enough for removal. They should then be lifted and transplanted at a wider distance apart, there to remain until the autumn or spring, according to the time when the sowing was made. September is a good month to transfer biennial plants to their flowering positions, although if a late sowing has been made the removal will have to be carried out in March. Each plant should be lifted with a good ball of earth to avoid undue disturbance of the roots.

Just a few biennials are best raised in cold frames. The most important of these requiring this attention include stocks, meconopsis, michauxia, Dianthus chinensis and Gilia coronopifolia. In some sheltered gardens stocks may be raised and grown on out of doors, but more often than not such serious losses occur during the winter that it is far better to have the young plants in a cold frame. The following biennial subjects are most worthy of the attention of the gardener:

CANTERBURY BELLS ARE EXCELLENT FOR MASSING IN CORNERS OF THE BORDER.
They are now obtainable in many shades of pink, blue and mauve and with single and double flowers. The large cup and saucer varieties are particularly effective.

Adlumia cirrhosa (*Climbing Fumitory*).—This hardy climbing plant is a native of North America, and it has much divided foliage and pretty flesh-coloured flowers. The species thrives in a warm light soil, and is at its best when growing against a wall or a fence at the side of which a few pea sticks have been arranged to aid in supporting the slender stems.

Androsace lactiflora (*Rock Jasmine*).—This charming little plant hails from Siberia, and as it is only about 6ins. high it is a good subject for the rock garden. The plant thrives in sandy loam and peat, and during the summer it produces its small white flowers in great abundance.

Aster Bigelovii (*Starwort*).—A very handsome biennial aster which grows to a height of 2ft. or more and produces masses of violet-blue flowers. A. Bigelovii is a native of the southern states of America.

Campanula Medium (*Canterbury Bell*).—Everybody knows these showy flowers, but it is worth pointing out that there are three distinct sections in cultivation, namely, those with single, double (var. flore pleno) and cup-and-saucer (var. calycanthema) flowers, the last named being specially attractive. The best flowering plants of Canterbury bells are secured by sowing the seeds in April or May. If potted up in the autumn and kept in a cold frame during the winter, Canterbury bells make very showy specimens for the cool greenhouse or conservatory, where they will bloom two months ahead of those out of doors.

Cheiranthus Cheiri (*Wallflower*).—Wallflowers are indispensable in the spring garden, and their culture is of the simplest. One important point to bear in mind is that the plants should be set out in firm ground, otherwise a great deal of sappy growth will be made and the specimens are likely to suffer during the winter. The pinching out of leading shoots is useful when wallflowers are young, for this ensures bushy plants that can be relied upon to flower freely.

Dianthus barbatus (*Sweet William*).—During recent years the sweet william has been enormously improved, not only in the size of its flowers, but also by the introduction of new shades of colour. To secure the best plants it is well to scheme for a long growing season. The seeds should be sown at the latest by the middle of April.

Dianthus chinensis (*Chinese or Indian Pink*).—The varieties of this plant are very showy indeed, and as they produce richly coloured flowers in varying shades practically through the summer, they are worth more attention than has been given to them. The seeds should be sown thinly in shallow boxes filled with light sandy soil in the summer. The young plants are wintered in a cold frame until planted out in April. The Chinese pinks must have a sunny position and light, rich soil. They are very attractive in flower beds and the blossoms are splendid for cutting. Chinese pinks may also be grown as annuals if seed is sown in a heated greenhouse or on a hot-bed during February. After transplanting the seedlings are kept under glass until May, when they are planted out. When treated as biennials, however, Chinese pinks usually give much better results.

A BORDER OF EVENING PRIMROSES.
A fine yellow flowered biennial.

Digitized by Google

Digitalis purpurea (*Foxglove*).—The strong point in favour of the foxglove is that it will grow almost equally well in shade or in sunshine. There are now many beautiful varieties of the foxglove, most of which are worth growing. The variety known as monstrosa or gloxinoides has a huge flower at the top of its spike. The giant primrose or buff-coloured foxglove is certainly a handsome form, and this comes true from seed. When once established in a garden, self-sown foxgloves will come up in abundance, and there is rarely any lack of young plants.

Erysimum (*Fairy Wallflower*).—These plants, which grow well in any ordinary garden soil, resemble wallflowers. They should be sown in the open during the summer, and in the following year they prove valuable for spring bedding in association with other plants.

Gilia coronopifolia.—This is a very striking half-hardy biennial with tall, unbranched stems 3ft. to 4ft. high. The flowers, which are produced in the summer, are of a reddish purple colour. The seeds should be sown in a frame during July and August.

Lunaria biennis (*Honesty*).—Honesty is one of the old-fashioned favourites which still finds a place in many gardens. In addition to the ordinary purple variety there is one with white and another with very deep purple flowers. Honesty is raised from seed without any trouble at all, and when once established there are usually plenty of new plants about.

Matthiola incana (*Brompton and East Lothian Stock*).—In recent years the attentions of amateur gardeners have been concentrated more on the annual ten-week stocks than on the Brompton and East Lothian forms. This is a pity, for there is something very stately about the Brompton group which is not so noticeable in the other kinds. Seeds of these biennial stocks should be sown in a cold frame in spring or out of doors in the summer. There are many fine sorts showing a wide range of colour. Many of the East Lothians bear very brightly coloured blossoms. Matthiola tristis (night-scented stock) has pale purplish flowers and is grown in a similar manner to the Bromptons.

THE OLD-FASHIONED HONESTY, LUNARIA BIENNIS.

A decorative biennial for outdoor and indoor use.

Meconopsis (*Himalayan Poppy*).—The Himalayan poppies will sometimes develop as perennials, but as a rule they are best treated as biennials. The seeds should be sown in April or May in a cold frame with partial shade. Pot the young plants separately and keep them in the frame during the winter, placing them out in April. Meconopsis like a somewhat shaded position and must have plenty of moisture. There are several very fine species, one of the best being M. Wallichii, the blue Himalayan poppy, which grows to the height of 4ft. or 5ft. and produces large numbers of blue or purple-blue flowers.

Michauxia.—A plant related to the campanulas, two species of which (M. campanuloides and M. Tchihatcheffii) are commonly grown. Both these have white flowers. The seeds should be sown in the summer and the young plants must be kept in a cold frame until the following spring.

Œnothera biennis (*Evening Primrose*).—This well known plant with its fragrant pale yellow flowers will always be popular. The variety known as Lamarckiana has much larger yellow blossoms and is a great improvement on the type. Self-sown seedlings of the evening primrose are abundant in many gardens.

Onopordon (*Cotton Thistle*).—Several of these striking plants are biennial in hab't. The seedlings come up freely in the open border. The three best of the biennial cotton thistles are O. arabicum with purple flower-heads, O. bracteatum, the silver-leaved thistle and O. Salteri with white stems. These cotton thistles often grow to the height of 8ft. and are most imposing subjects.

Verbascum (*Mullein*).—Two kinds of mullein are biennial, and both of these will seed freely in any common soil. The species are V. olympicum and V. phlomoides, both of which have yellow flowers.

LATE-FLOWERING ROCK PLANTS

THE great aim of everyone who loves or tends a rock garden should be to keep it interesting and beautiful all the year round. With careful management it is possible to have a few flowers in evidence, even through the depth of winter, and new late summer and autumn flowering plants are frequently added to the catalogues, making it possible to have quite a bright display until October.

The great wealth of plants that bloom from March until June makes it fairly certain that there will be a wealth of flowers during that period, and in too many places the rock garden or rockery is scarcely visited after that time, and its interest is said to be over for the season. Supposing the rock garden is more or less planted on the bedding-out principle with masses of aubrietia, mossy saxifrage, early-flowering sedums, etc., its beauty is bound to wane and the interest in it to grow thin about midsummer; but with the great wealth of plants obtainable an almost even display can be kept up until autumn.

It may appear to be a heresy, but I, for one, think it is quite possible to have too much colour in a rock garden at one time, especially when that mass of colour is obtained early in the season at the expense of the summer months. Great drifts of aubrietia, mossy saxifrage, iberis, alyssum and similar things make a brave show while they last, and that is the best that can be said for them.

GENTIANA SINO ORNATA—THE FINEST OF LATE FLOWERING ROCK PLANTS.

A quieter and more natural effect is obtained when the above and other early subjects are planted almost alternately with late-flowering plants, thus giving patches of restful green between each mass of colour. And you have the feeling that you are not prodigally using all your treasure at once. There is no need for this method to produce niggled effects, for a good large pocket or ledge filled with a given subject is far more pleasing than isolated plants scattered indiscriminately all over the rock garden. The system also does much to prevent the inevitable clashing of colour when a great number of shades come very close to each other.

Digitized by Google

Any good catalogue of rock plants gives the months in which the plants bloom, and it is easy work to find a good number that are at their best in August and September, and a few that are interesting through October. And it is wonderful how much longer some of the early plants will keep in bloom if their seed-pods are removed. The production of masses of seed heads is a great strain on the plants, and if time can only be found to remove these when the flowers fade the majority of things will flower a second time. This I have proved with many of the mossy saxifrages, and nearly all campanulas can be carried well into the autumn by the same simple means.

If asked to name plants suitable for a late display my thoughts would first turn to Androsace lanuginosa, for it is easy to grow and a joy from July to October. Old worn-out plants may not do well, but young plants, which may be easily struck from cuttings in a frame during summer, will trot about like miniature verbenas, and grow into large plants the first season. The best place for it is on a ledge or in a small pocket, where it can droop over a rock, which shows up the silvery foliage and bright flowers with best effect. No matter if the plants appear to suffer in the winter, for they will spring up strongly from the base in spring, and are all the better for a severe cutting back in March. The companion variety, A. lanuginosa oculata, should also be planted.

The gentians are good subjects but they are not everybody's plants, and they may fail to do well in some gardens. But they are very beautiful, and if the conditions that suit them are borne in mind there is little fear of failure. One of these, at least, Gentiana lagodechiana, I have found very easy to grow with a west or east exposure, and it is quite comparable with the spring joys, G. xerna and G. acaulis. And there are at least six other late-flowering kinds worth considering, above all the beautiful G. sino-ornata with its trumpet flowers of brilliant azure blue.

Another autumn favourite is Zauschneria californica and its varieties. Given a place on a warm sunny mound or ledge, where it will never get too wet, it simply luxuriates, and is capable of diving under a good big rock and coming up on the other side of it. The silvery foliage makes a suitable setting for the crimson flowers.

Last autumn I saw a patch of Verbena chamædrifolia upon an amateur's rock garden that was a glowing mass of crimson, and yet not so crude a colour as to be offensive. The one thing against it is that it is not quite hardy in some districts, but it is an easy matter to save some cuttings in a cold frame.

Most of the small campanulas carry on for a long time, and their first cousins, Platycodon Mariesi and its white variety, produce their large blooms all through the summer. Viola cornuta remains in bloom for about nine months of the year, and the true papilio varieties are good enough to grace the most elaborate rock garden. Even such a commonplace plant as Polygonum vaccinifolium provides an attractive carpet of pink late in the season.

A long list of names might be given, but they are all found and dated as to their flowering season in the right catalogue, and it is enough to say there are gems under the names of achillea, chrysogonum, erigeron, erodium, linaria, mimulus, papaver, potentilla, sedum, silene, statice and veronica. Nor should the bulbs Zephyranthes candida and the autumn-flowering cyclamen and colchicums be forgotten.

Nearly all rock plants are now supplied in pots, so that it is possible to make renewals at almost any season of the year. All these late-flowering plants do well if planted in the spring, and the majority make good clumps before their flowering season. With these, and with good breadths of fine foliage for the winter, the rock garden may be made beautiful and interesting through every month of the year. T. H. W.

AURICULAS for the BORDER and ROCK GARDEN

These have been at their best for the last two or three weeks, and now is the time to undertake cultural treatment, such as repotting for increasing the stock for next year.

THE auricula has been a great favourite for many years, and here we have a choice group of plants admirably suited for the cold frame; while many are available for the flower border and rock garden. It should be borne in mind that the auricula is quite hardy, and the real object of the cold frame is to preserve the meal or farina on the leaves of some varieties, while the flowers are protected from rain, when their full beauty is revealed. The auriculas are divided into several groups, such as alpine, selfs, white-edged, green-edged, grey-edged and fancies. The first-named section contains the finest of the auriculas, both for frames and the border.

A wood frame will answer the purpose well; then it can face south during the winter, and be placed on the north side of a wall or building for the summer.

Repotting.

In April the plants will be in full bloom, and as they pass the flowering stage the annual repotting is carried out. The end of May should see this work completed, and the plants set out on clean ashes in the frame, where they will soon become established if lightly shaded from strong sunlight. Over-potting must be guarded against, and, for specimens that have reached their maximum, pots 4ins. to 4½ins. in diameter will be ample; while many plants will take a smaller receptacle. Good drainage is essential, and the compost should consist of fibrous loam 3 parts, leaf-mould 1 part, with a liberal sprinkling of silver sand or crushed oyster-shells added to render the whole porous. Most of the soil should be removed, the tap-root shortened if needed, and any woolly aphis found on the roots destroyed with tobacco powder or methylated spirit, the latter being applied with a small camel-hair brush. Press the soil fairly firm, and when the repotting is completed the leaves should be on a level with the soil.

For a few weeks give just enough water to keep the foliage plump, but directly root action is vigorous the supply must be increased. When this stage is reached the lights can be removed both day and night, providing there are no signs of heavy rain. About the end of October less water will be needed, and during the winter months very little is required, because damp is the chief enemy of the auricula at this period. All dead and dying leaves must be removed when they will part readily from the stem; and if there are any signs of decay, dust the affected parts with powdered charcoal. In the spring, when the spikes appear, the roots must be kept moist, and when the flowers begin to open a light shading will enhance the colour of the blooms. Admit plenty of air on all favourable occasions.

A FINE SHOW AURICULA.

As the plants are going out of flower now they can be repotted. Plants growing in the border can be increased by taking offsets and inserting them in fresh soil, where they will root easily.

Offsets.

Named and special varieties are increased by means of offsets, these being removed from the parent plant in February, at the time of potting on in August. Those with a few roots attached are best potted off singly, while others without roots should be placed around the sides of pots until rooted. If potted on as required, these will soon make flowering examples. Auriculas may also be raised from seeds; but remember, germination is often slow, and seedlings may appear at intervals for twelve months or even longer.

Insect Pests.

Green fly and woolly aphis are the chief insect pests; the former is easily destroyed by fumigation, and also the latter if above the soil. Those beneath the soil are dealt with when the annual repotting takes place.

The chief factors in the successful cultivation of auriculas are cleanliness, keeping the plants cool, careful watering, prevention of damp (such as drip from the lights), allowing no water to accumulate in the heart of the plant, and giving plenty of fresh air whenever the weather is dry. W. B.

PLANTS FOR SMALL TANKS AND POOLS

There are any number of moisture-loving plants which can easily be grown in a small garden if given a situation round the margin of a small pool, while water lilies and other aquatics can be planted in the pool or tank itself. A few of the best are described in the following article.

THE beauty and interest of any garden is considerably enhanced by adding a few representatives of desirable aquatics or bog subjects. Nothing adds more to the delight and restfulness of a garden, even a small one, than water in the form of a small tank or pool. In these notes I shall cater for the small garden, such as I visited the other day. It consisted of a small more or less circular rock garden with a cement tank in the centre. The difficulty which confronted the owner was what plants to place in this tank. Regarding the tank or small pond, the area covered is a detail to be settled on the spot. It may only be a few feet in length and less in width, but the depth is all important. If it is desired to grow some of the larger nymphæas, then a depth of 3ft. to 4ft. is required, and, of course, to be really effective the whole should be on a larger scale. However, as small tanks are the subject of this note, there is no necessity for them to be so deep; 1ft. to 2ft. in depth is ample, and whenever possible I would choose the highest figure. When lining the tank or pond with cement, the average bricklayer will make it as smooth and shiny as possible, but this crude method can be considerably improved by sprinkling ordinary gravel over the cement before it becomes set or rigid. While recognising that the square or oblong tank is the only possible one in some gardens, there are many where the design could well be somewhat irregular and, consequently, much more effective. Where the tank is formal in outline, it could be improved by an occasional rock garden stone, especially if it was carefully selected with a few chinks and crannies in it which would be planted with a number of small-growing alpines. The edges of small tanks are sometimes rather glaring, particularly when the water is a few inches below the normal level. This defect can, however, be remedied by the judicious planting of a few creeping plants which will break up the line if not entirely cover the unsightly edge. Here and there the king cup, Caltha palustris, and C. polypetala will be effective if given an occasional watering, or the various forms of Trollius europæus, Primulas rosea, sikkimensis, japonica and denticulata would look well. Mimulus is also very fine, especially the varieties so easily raised from seeds; while the forget-me-not, Myosotis palustris and cardamines are also useful. Where the pond or tank is surrounded by grass no plants will be needed, because the turf can be laid level with the edge of the water.

CROWNS OF WATER LILIES PLANTED IN BASKETS AND PLACED IN POSITION IN A SMALL POND.

For the smallest tank, or even a tub, the small-growing water lily, Nymphæa pygmæa alba, is strongly recommended. with its pure white flowers, while N. p. helveola is a shade of sulphur. In one illustration is seen crowns or plants of this nymphæa such as are received from a grower, and in the other picture the same plants are ready for placing in the water, but a couple of stones may be needed to keep them in position. Old baskets are often recommended for water lilies, but I have used a piece of discarded wire netting for this purpose. The receptacle is merely a detail, but it should be of sufficient durability to remain intact until the roots have taken possession of the soil. This consists of partly decayed turfy loam with a little rotted manure. No further attention will be needed for some time, but in confined quarters it is advisable to lift and replant every four years to prevent overcrowding. The best time for planting aquatics is mid-April for mild areas and May for colder districts. Other suitable nymphæas are NN. odorata minor, yellow; gloriosa, red; Laydeckeri rosea, rose; Frœbelii, deep crimson; Aurora, orange red; and W. Falconer, rich bright ruby. There are a few others suitable, but the owner of a small tank will only need two or three plants, because each one will require a surface space of 3 or 4 square feet to develop its leaves and flowers during the summer months. In conjunction with water lilies we ought to encourage a few other plants, such as the water hawthorn, Aponogeton distachyon. It produces fragrant white flowers which float on the water, and it is always effective. Ranunculus aquatilis will stud the pool with myriads of white flowers with yellow stamens, but this plant is occasionally rather rampant. Stratiotes aloides, the water soldier, is also white, and Butomus umbellatus, the flowering rush, is pink, while the bog bean, Menyanthes trifoliata, is interesting with its rosy white flowers. The chief fault of this plant is that it is overvigorous and needs reducing occasionally to keep it within bounds. For our purpose the water violet, Hottonia palustris, is available, the pretty rosy lilac flowers being produced in whorls, the spikes rising about 1ft. above the water. The floating water plantain, Elisma nutans, is a rare British plant of neat habit and three-petalled white flowers. The small floating aquatics are merely placed in the water, but those with a quantity of roots are treated similarly to the water lilies, but much smaller receptacles will suffice. A constant flow of water is not essential to the well-being of aquatics, but it will be found an advantage to have a water tap in close proximity to the tank. An outlet may be desirable, but not a necessity, evaporation will account for a certain amount of water, and if this loss is made good from time to time the water will remain in excellent condition and not be objectionable. Water gardening may be termed one of the latest phases of hardy plant culture, and its devotees (especially in a small way) are becoming more numerous each year.

THE BUSY MAN'S PAGE

Polyanthus Primroses.

Sow Seeds Now.

JUST now these old-world spring flowers are making a fine show, not only in the garden but in the woodland, where the partial shade encourages the varied colours and tints to develop to the best advantage. Seedlings, undoubtedly, give excellent results, especially if a good strain is obtained, and if not already done the seeds should be sown at once. Directly the seedlings are large enough they should be transplanted on a partially shaded border in lines 1ft. apart and about 6ins. between the plants. Here they will thrive until the autumn, when they can be transferred to their flowering quarters.

Plants that are flowering this year will be found useful for the wood or copse, and the best of the varieties can be marked while still in flower with a view of increasing the stock of these extra fine forms. When the flowering period is over, the plants are lifted, divided into single crowns, and planted in rows similar to the seedlings. These will make good specimens for next year. If the weather proves dry, the roots may require a little water until they are established.

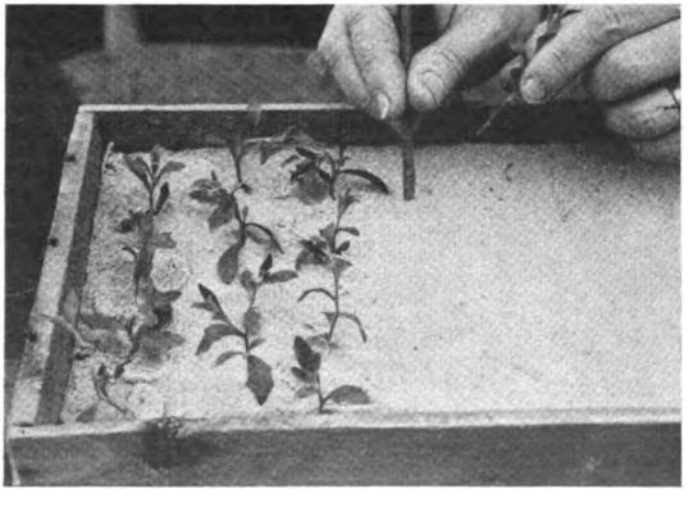
There are some excellent strains of polyanthus in existence, such as Giant White, Giant Yellow, the magnificent Munstead strain which contains fine shades of yellow and pure white, crimson and mixed varieties. may be increased by cuttings. These are best taken when the plants pass out of bloom; secure them some 2ins. or 3ins. long and dibble into a sandy, shaded border or into boxes in a cold frame; those in the open will strike more readily if covered with a handlight, after being watered, while any in the frame may be shaded for a time. At no time allow the soil to become dry, yet do not sour it by repeated and unnecessary soakings. Growers who sowed seed earlier in the year in order to secure extra large plants the first year, may give their plants ample ventilation from now on; plant out during moist weather in June, July or August. After flowering is over, cut back large tufts; in this way they remain manageable, compact and beautiful.

DAFFODILS AND EARLY FLOWERING TULIP BULBS CAN NOW BE LIFTED AND LAID IN A BORDER OF SOIL AND THE ROOTS ROUGHLY COVERED OVER.

They can be left there until July or August when the growth will be thoroughly ripened and the bulbs ready for storage.

Increasing Aubrietias.

AUBRIETIAS are easily raised from seed, which may now be sown in the open border, or at any time until the middle of June. Select a semi-shaded border for the purpose, then rake the surface into the finest possible tilth; draw out the necessary number of shallow drills, 6ins. apart. Place a handful of dry sand in a bowl and into it carefully pour the fine seed; mix thoroughly, and scatter sand and seed along the shallow drills; cover with the thinnest covering of soil. Germination does not take long in such a border, but the seedlings progress very slowly; when they do become sizable, pick out those which are causing overcrowding and transplant. During hot weather, keep the soil moist and dew the plants overhead in the evenings. Transplant in autumn or early spring, into permanent quarters. When named or choice varieties are grown, they



INCREASING AUBRIETIAS BY MEANS OF CUTTINGS.

These should be about 2ins. or 3ins. long and placed either in a sunny border outside or in a box in a cold frame. Choice named varieties can be increased in this way.

Renovate Room Plants Now.

THIS is the best time of year in which to renovate room plants, so that they may continue in health and vigour for another year, at least. They may not need repotting, but, in such a case, we recommend that some of the old soil be picked out and new loam put back in its place, with some leaf-mould or manure added in the case of green plants. When repotting, pick out much of the old soil with a blunt stick before repotting, and then put the plant back in the same pot or one a size larger; should the soil be wet and the plant sickly, wash its roots clean in water and then repot. In practically all cases, too, pot up firmly, ramming the soil in round the old roots carefully with a blunt stick. Palms, aspidistras and the like will be rejuvenated if the leaves are individually laid on a board and sponged with lukewarm soapy water; spray afterwards with cold clean water, but on no account sponge with milk, oil, etc. Aspidistras with variegated leaves are potted up with loam only, not rich loam, and the pot should first be nearly half filled with crocks. Do not imagine that cigar ash, oil, cold tea and the like are good for house plants; they are not to be used at any time. Water plants by dipping them in water for ten minutes; allow to drain for another ten minutes at least before replacing in saucers; do not add driblets of water daily, but water as above when required.

Bulbs After Flowering.

BULBS planted in permanent stations need no attention, they will look after themselves, but it is those bulbs grown in pots, beds, window boxes and similar positions, that will, with proper treatment, recuperate and flower freely again in two years' time. Narcissi, which first of all did duty in pots, can be planted out in the woodland or under deciduous trees. Even tulips succeed in the grass where the turf is not too dense. When the daffodils, hyacinths and early-flowering tulips are past their best, all the old flowers should be removed, with a view to preventing the formation of seed pods, which will considerably weaken the bulbs. In many instances it will be necessary to remove the bulbs before they have completed their season's growth. Now this should be carefully performed; lift them with plenty of roots and with as little damage to the foliage as possible, after which they are laid in soil in any part of the garden till the bulbs have dried off. If the weather is dry, give an occasional soaking of water and bear in mind that the bulbs can be arranged closely together. When the growth is fully ripened, lift the bulbs and store in a dry shed till August or September, when they can be planted in such permanent places as described above, or in other parts of the garden, where they will eventually furnish a lot of useful flowers. The May-flowering tulips ought not to be lifted till the end of May or early June.

The Value of Mulching.

IT is almost impossible to over estimate the importance of a mulch or surface dressing of manure, leaves or some other material to the surface of the ground about the roots of trees, shrubs, herbaceous plants, vegetables, fruit trees, etc. The beneficial effects are soon to be noticed, particularly during a long period of dry weather. The mulch not only acts as food for the surface roots, but it checks the parching effects of the sun's rays and prevents excessive evaporation of moisture from the soil. A good mulching soon pays for itself in the time saved over watering. Where an unmulched plant might require almost daily watering, those which are protected in this manner will often stand well for several weeks without any further attention. Quite the best time to apply the mulch is in the later part of the spring, for by then the soil has become a little warmed after the cold of winter.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Chrysanthemums for the Border.

THERE is no doubt about the popularity of the early-flowering chrysanthemums. A grower of cut flowers for market assured me that no matter how fine China asters may be, as soon as the chrysanthemums appear they are always favoured. This is doubtless due to their lasting qualities and to the wide range of colours. Any ordinary garden soil is suitable if the ground is well dug previous to planting. Manure should be added if it is very poor. Chrysanthemums like a fairly sunny position, and will not flourish under the shade of trees. Set the plants 18ins. or 2ft. apart, preferably in groups of three. It is advisable to put in a stake about 2ins. from the main stem, to prevent the tender shoots from breakage by the wind.

Old Plants.

Where roots of hardy chrysanthemums have been left in the border all the winter, these can now be lifted, divided and replanted. This division makes a surprising difference in the quality of the blooms, and I certainly advise that it should be done each season. In the north where it is customary to winter plants in a cold frame, the light should be left off for a few days before the plants are set out in the border.

Good Varieties.

In making selections among so many sorts of hardy chrysanthemums, with such widely varying colours and characteristics, we gladly take as a guide the results of trials made by the R.H.S. in 1923. In these, 270 varieties were planted, and from those which received the awards of the committee of experts I have made a selection of some most useful to the small gardener. All these flower early, *i.e.*, before the frosts come to spoil the outdoor blooms: Framfield Early Primrose, September white, Horace Martin (yellow), Golden Almirante, Bronze Goacher, Freda (pink), Mme. M. Masse (mauve), Mrs. W. Sydenham (crimson), Jamie (purple). A few good singles are Golden Firebrand (very early), Taplow White, Fairy (pink and white), Midnight Sun (fiery terra-cotta). Single varieties lack the sturdy habit of the doubles for withstanding autumn winds and rains.

Enemies.

The tender growth of chrysanthemums is readily attacked by black fly and the leaf miner. The maggot feeds on the tissues between the two surfaces of the leaf, causing whitish patches which are unsightly and affect the plant's health. As a preventive of this, and also of black fly, spray the leaves during June with extract of quassia or paraffin emulsion. Where the leaf miner is observed, pinch the leaf between the finger and thumb to kill the maggot.

MAY IN THE TOWN GARDEN.

WHAT TO DO THIS MONTH.

1. *Plant out stocks, asters, pentstemons, calceolarias and all summer bedding plants.*
2. *Keep clematis, climbing knotweed and other creepers tied up as they grow. Otherwise they become entangled.*
3. *Prune early-flowering shrubs after they have flowered.*
4. *Plant out dahlias. This is the time to purchase new varieties.*
5. *Sow seeds of biennials, such as honesty, wallflowers, Canterbury bells, forget-me-nots, etc.*
6. *Syringe roses and other plants immediately green fly appears.*
7. *Keep the surface soil loosened between growing plants to prevent loss of soil moisture and to keep down weeds.*
8. *Thin out seedlings growing in the borders. Six inches between each plant is the minimum for most annuals.*
9. *Give water to climbing plants and wall trees that are grown against house walls. A good soaking occasionally is better than frequent surface waterings.*
10. *Syringe or sponge the foliage of smooth-leaved plants if the weather is dry. Do this in the evening.*
11. *Sow beetroot, also salad crops, such as radishes, mustard and cress, lettuce, etc.*

Summer Flowers.

FOR long months they have remained behind the closed doors of greenhouse and frames. Very patiently have they waited, and now the order for their general release has come. May brings with her a free pardon for the imprisoned summer plants, and soon they will come on barrows and carts to the markets, and thence to the homes of the amateur gardeners. The raising of summer bedding plants is an enormous industry and I have sometimes been staggered by the sight of the quantities of plants inside the greenhouses of our large nurseries. Petunias, fuchsias and lobelias and all such plants fill the houses to overflowing at this, the busiest season of the nurseryman's year.

Those who have not grown petunias will find them the earliest of flowers with which to make a display. They like a rich soil, and well decayed leaves or similar matter should be dug into the soil where they are to be planted. They have specially good points for the small garden, as they flower continuously for a long period if care is taken to remove dead blooms, and their colours are particularly bright and attractive. A fairly sunny position should be chosen and during dry spells water should be given. Petunias are specially good plants for window-boxes and they grow freely in town gardens, where they particularly appreciate an evening showerbath after hot sunny days.

In a limited space it is of first importance that the plants selected should flower soon, and should flower for a long period. I would suggest for this purpose the following: snapdragons, stocks, pansies and violas, pentstemons for sunny gardens, and calceolarias and tobacco plants for shady gardens. To these, of course, could be added such plants as carnations and geraniums.

A SMALL TOWN GARDEN MADE BEAUTIFUL WITH SUMMER FLOWERS.
Now is the time to prepare for a bright summer display.

Garden Competitions.

READERS who have entered their gardens for local garden competitions will be interested in the points which the Gardens Guild judges look for when the garden inspections are made. A maximum of 40 points is awarded on the following basis:

Culture	20
Design, arrangement and difficulties overcome	10
Cleanliness of soil from weeds and plants from pests	5
Special features ..	5
Total ..	40

It behoves all amateurs to try as far as possible to achieve success in each section and thus attain the maximum number of marks.

NOTES ON THE FLOWER GARDEN

Dwarf Campanulas for the Rockery.

THE great interest shown to-day in rock gardening has brought into prominence plants of a diminutive character, and it is questionable whether at any other period there have been more growers of them. Among subjects which can be employed in a variety of ways in a garden, dwarf campanulas are now receiving a large share of attention, and every year almost we find additions to their ranks. Few things about a rock garden or rockery give greater pleasure or, when once established, take less looking after. At this season of the year many plants change hands, and to those who may not have had much experience in procuring them from a distance, it does not, as a rule, appear to matter very much as to *how* plants may have been grown for the purpose of despatch so long as they reach their destination.

CAMPANULA GARGANICA OF SOMEWHAT TRAILING HABIT, A FINE MINIATURE BELLFLOWER FOR THE ROCKERY.

Advantage of Pot-grown Plants.

It is just here where the beginner fails to appreciate the advantage of campanulas (and many other rock plants) grown in small pots, and turned out and carefully packed for removal, over those lifted from a bed which also have to travel by train or through the post. There is no doubt that losses among pot-grown plants are few in comparison with those whose roots are disturbed and have to be sent on a journey. I mention this for the guidance of those who may be adding to their collections. Many firms recognise the necessity of growing plants for this important department of gardening in pots, and the little cost which is added is scarcely worth consideration when one weighs the advantage.

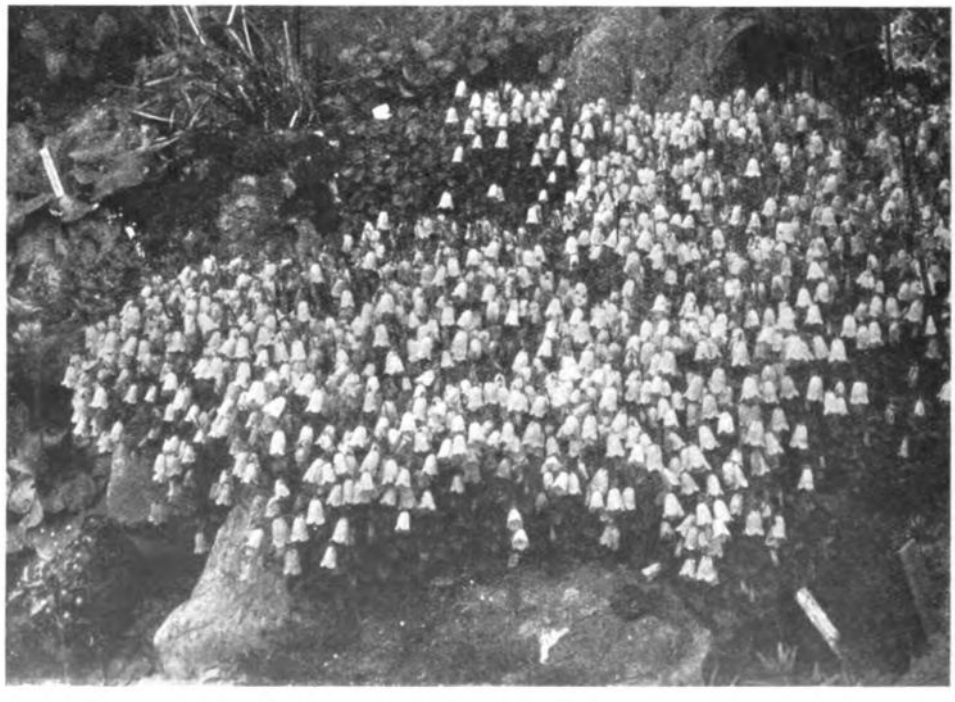
Propagation.

A few plants purchased to form the nucleus of a collection will enable one to get together a stock in a year or two. Many campanulas perpetuate themselves from seed, so that once a plant has become established and flowered, seeds drop and plants spring up. An examination of a flagged path in my own garden the other day revealed minute seedlings coming up, the result of self-sown seed last year. Personally, I think there is more success following the sowing of seed of campanulas and some other subjects in crevices of stones than in planting young grown plants, as they often adapt themselves more readily to their environment. Propagation may also be effected by splitting up the roots in spring, and also from cuttings taken after flowering, and inserting these in pans or boxes of light soil in which sand has been incorporated. They should be kept in a cold frame for a time, preferably in a north aspect, or at any rate should be shaded until roots have formed. Plants are better divided every two years or so.

Varieties.

As to varieties in dwarf campanulas, there is great choice, but some of the older forms are still hard to beat when one remembers their free-flowering qualities for edging purposes, for planting in niches in the rock garden or between stones in paths.

Appended is a short list of sorts that, planted in any moderately good garden soil in which grit or sand has been incorporated, will do well in most places: pulla, purple, 4ins. to 6ins.; cenisia, pale blue, 4ins. to 6ins.; G. F. Wilson, deep blue, 9ins.; Portenschlagiana (syn. muralis), blue, 4ins.; carpatica, in blue and white forms, 6ins. to 9ins.; garganica (a trailing variety), blue; turbinata, greyish foliage, flowers borne singly on stems of about 6ins. in height, deep blue.—F. W.



THE DAINTY NODDING BELLS OF CAMPANULA PULLA.

Loosestrifes.

THE lysimachia and lythrum, which embraces the white and yellow and purple and rose forms of loosestrife, are widely distributed, particularly Lysimachia vulgaris, which is to be found in all parts of the country. It is a tenant of streams and ditches, producing panicles of yellow flowers in profusion, and is not without value when kept in hand in shady borders or shrubberies. One of the most familiar as a creeper, found on old stone walls and in many country gardens, is the creeping jenny (L. Nummularia). It is used often for planting in window-boxes for draping the fronts with yellow flowers. L. clethroides makes a good border plant. It is a Japanese species growing 2ft. or 3ft. in height, producing spikes of white flowers and adding to its beauty in autumn by its highly tinted foliage. These will grow almost anywhere in a garden, but should have a place away from other plants, as the roots permeate the soil, necessitating frequent division to keep them within bounds, and, further, ought to have the advantage of a moist, shady position.

The purple loosestrifes, like the preceding, love a moist, deep soil, though they are not absolutely dependent upon it for growth, as witness plants growing on slag heaps, among cinders on railway embankments. Others that make handsome plants for growing in a garden are distributed under the genus lythrum, and of these virgatum (rosy purple), Rose Queen (bright rose) and atro-purpurea (purple) make handsome plants for the shady side of a garden, growing about 3ft. in height and retaining their flowering spikes for several weeks. They are easily propagated by division of roots, which is best done in autumn.—C.

Double Herbaceous Peonies.

ALTHOUGH catalogues list a fairly large number of double herbaceous peonies, these fine flowers do not seem to have captured the gardening fraternity yet, and really few varieties are widely known. They are easily grown; in a medium loam and with a light dressing of manure dug in round the roots every spring, they grow strongly without further care or attention. As supplied from the nursery, the plants are generally two or three years old; they may not flower the first year, even at that age. They are glorious plants when in bloom, although some years for some reason or other they fail to flower. Among the best I would class Agnes Kelway, Boule de Neige, Lemon Queen, Canary Yellow, La Tulipe, The Bride, Roses elegans, Sarah Bernhardt, Enchantress, Lady Bramwell and Odette. It is much too late to plant this year, but intending growers ought to visit a nursery in June and pick those colours which they think suitable.—H. H. A.

A Handsome Garden Pea.

Lathyrus grandiflorus.

IT is not often that one sees this fine pea well used, unless it is in cottage gardens, where it has always been a favourite. But few plants are better for rambling up to 4ft. or 5ft. among other growths on a bushy bank, or in garden ground over cleverly placed short pea sticks. The flowers, borne in pairs on stalks about 2ins. long, are large and showy—nearly 2ins. across the flattened wing. They spring from axils which are also furnished with a pair of leaves on 1in. stalks, ending in a longer tendril, so that each pair of flowers is well supported. The colour is a bright crimson, shaded—too near magenta to be quite pleasing, though this rank quality is more or less condoned because of the undeniably handsome effect of the whole plant. Looking into the flower, one sees how the keel is curiously twisted, first to the right and then finishing to the left. It should be planted cautiously, as it rambles freely at the root.—J.

LATHYRUS GRANDIFLORUS MAKES A CHARMING RAMBLER IN AMONG SHRUBS.

How to Increase Sweet Jasmine.

AN easy way of increasing the stock of this sweet-scented climber is to look round the base of an old plant for rooted shoots or suckers. These, if removed at once from the parent plants, shortened to a foot and replanted, will quickly become established. There are usually several such shoots to be found in the position indicated, and there is very often room for a few vigorous specimens of this highly esteemed favourite for covering walls and porches.—C.

A Decorative Shrub.

CLETHRA ALNIFOLIA is one of the hardier species of the genus, some of which are too tender for our gardens except in the extreme south or west. The creamy flower spikes are all the more welcome because they come in August when so few shrubs are in bloom. It is a native of the United States. The illustration shows a small portion of a bush about 7ft. high that is growing in a sheltered shrubbery in a west Surrey garden, partly protected by a neighbouring bamboo.—G. J.

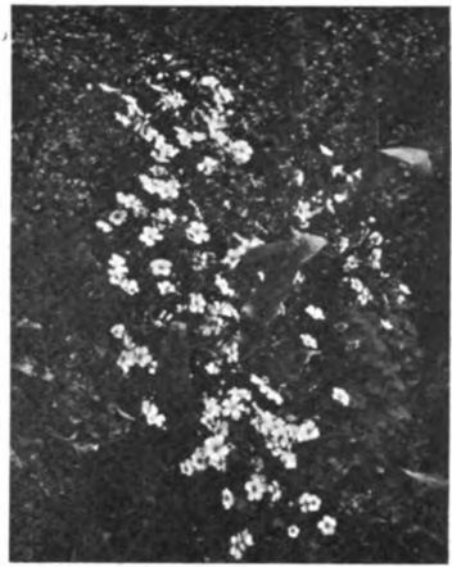
THE CREAMY FLOWER SPIKES OF CLETHRA ALNIFOLIA LOOK MOST DECORATIVE IN A SMALL SHRUBBERY.

Plants for Flagged Paths.

WHEN plants are received for setting between spaces in flagged paths it is not enough to scoop out the soil and press them in, as not infrequently it is sad and heavy. The better plan is to raise the stones temporarily, replace the old soil with light, gritty compost, plant the clump, and then put back the flags. By doing this it is more likely that campanulas, and in fact any other plants, will establish themselves more quickly.—F. W.

An Admirable Rockery Plant.

ONE of those satisfactory plants whose flowers look large in proportion to the size of the plant is Arenaria montana. The pure white bloom is not only large but is abundant, often almost covering the prostrate cushions of leaf and stem, which are seen at their best when hanging over rocky stonework. It is easily raised from seed, but if seed is to be kept from home-grown plants, it should be looked for early, as it ripens quickly and may easily be lost by delay.—G. J.



ARENARIA MONTANA WITH ITS CUSHIONS OF PURE WHITE BLOSSOMS IS A FINE PLANT FOR THE ROCKERY.

Silvery Edging Plants.

EDGING plants, the foliage of which is of a grey or silvery colour, have much to commend them, as, during the summer, even when they are not in flower, they make an attractive finish to borders or beds. Cerastium tomentosum is quite hardy, and will often thrive in dry positions and soil that is sandy. It grows about 6ins. or so in height, the leaves are whitish, and the innumerable flowers are pure white. It can be raised from cuttings taken after plants have done flowering, and inserted in a bed of sandy or gritty soil, shading the bed for a few days if necessary. Cerastiums can also be raised from seed, which may be sown in a cold frame or warm border in May or June. Among antennarias that serve a useful purpose as edging plants, being hardy and dwarf, and needing only ordinary soil and simple culture, but prefer sunny places in a garden, A. tomentosa is one of the best known. A. minima makes a suitable plant for carpeting or edging. Both have whitish foliage, and grow only a few inches in height. The flowers are of a daisy-like character. Division of roots in spring is a favourite method of perpetuating antennarias, though they can also be raised from seed. Cineraria maritima is a half-hardy perennial with finely cut silvery foliage, sometimes used near the edge of a border, which has been superseded by C. m. Diamond, with snow white leaves, and has become popular as a bedder. They can be raised from seed sown in heat in spring, but it is only on older plants of the second or third season in the case of maritima that the whiteness of the foliage is best seen. After Pink Mrs. Sinkins has passed out of flower the neat grey foliage makes a good edging for several months.

ZONAL PELARGONIUMS FOR WINTER FLOWERING

Few plants give less trouble or are easier to manage in the small greenhouse. The plants can be gradually hardened off this month and placed out of doors during the summer.

IT is somewhat surprising that more amateur gardeners who have at their disposal a conservatory or greenhouse from which frost can be excluded, do not grow the popular "geraniums" for brightening this structure during the winter months.

When a good winter display of bloom is required, the plants must be grown specially for that purpose; it is useless to lift plants from the best in the autumn, pot them up, place them in a greenhouse and expect them to continue blooming throughout the winter. That is expecting too much, and can only result in disappointment.

The best plan is to use plants which have been raised from cuttings taken from stock plants in February or March. These cuttings must not be dried off at all before insertion, as are the autumn struck cuttings, but should be trimmed with a sharp knife and inserted singly in thumb pots containing a sandy compost and placed in a propagating case, leaving a little ventilation always on the top of the case. On bright mornings the cuttings may be given a very light mist over with a fine syringe; the object being to prevent them from flagging and they may be lightly shaded from bright sunshine. As soon as they have rooted, which will usually take place in about a fortnight, remove to a position near the glass in a house having a temperature of 50 to 55 degrees.

Should the amateur not have facilities for propagating his plants in this manner, they can be purchased very cheaply now from any reputable nurseryman.

The plants may be potted from the thumb pots in large 60's, using a compost consisting of two thirds fibrous loam, one third leaf mould, and a liberal admixture of silver sand and old mortar rubble to render the whole open and porous in texture; pot firmly and return to the shelf in the greenhouse. Do not apply water until absolutely necessary, it being better to allow the roots to commence growing into the new compost, which should be just pleasantly moist, before additional moisture is supplied.

Gradually harden off and in May they may be transferred to a cold frame and treated in the same manner as are the bedding geraniums. If necessary, the point of the leading shoot may be nipped out to ensure a bushy growth. When well rooted round, but before they become pot-bound, transfer to 5in. pots using a similar compost, but with the addition of a little dry cow manure and bone-meal. As before, take care to pot firmly, using a wooden rammer for this purpose. A final shift into 6in. pots may be given as soon as necessary.

When all danger of frost is past, stand the pots on a bed of ashes in a sunny position and the only attention necessary during the summer will be to water carefully—never allowing the plants to suffer for want of water—and to remove any flower buds which appear. When well rooted, applications of dilute liquid manure and soot water at regular intervals will be beneficial, but too much must not be given, otherwise soft, unripened growth will be produced.

Towards the end of September remove the plants to a light position in the greenhouse, first of all scratching away a little of the surface soil and replacing it with a little new soil containing about one third its bulk of Clay's Fertiliser. The pots should also be washed before housing. On no account must the plants be overcrowded, otherwise they will lose much of their foliage. Ample clearing space must be allowed between each plant.

Plenty of ventilation must be given when the plants are first housed and even during the winter it is only necessary to maintain a minimum night temperature of 45 degrees. Watering must at all times be performed with care, taking care not to allow the soil to become sodden, but at the same time the plants must not suffer from excessive dryness. In damp weather a chink of air should always be kept on the top of the house and the requisite temperature maintained by a little fire heat, this also assists in maintaining a dry atmosphere.

From September onwards the flowers must not be picked off, but as soon as each flower bud appears the tip of the shoot should be nipped out immediately above it; this concentrates the energies of the plant into the developing flower and a fine large truss of bloom results.

Given this treatment, zonal pelargoniums will give a continuous display of bloom throughout the winter and at this season their brilliance enhances their value.

T. H. E.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

"WINTER lingers in the lap of May" and justifies the exercise of caution on the part of amateurs engaged in garden work north of the Border. Recent weather experiences are not usually associated with late spring and early summer, but recall the conditions that are more general in December and January. Successive days of alternating falls of snow, hail and rain were followed by sharp frosts varying in their intensity from 9° to 12°, while the prevailing north-east winds contributed to the cold snap and inflicted damage to vegetation that is widespread and incalculable. Seedling vegetables, particularly turnips, that had appeared above ground, were ruined; sweet peas that were planted out or in process of hardening off had their foliage discoloured; the fresh green growth on the rose trees is now brown; and fruit bud and blossom have suffered in a more or less degree according to the situation. All this is discouraging to gardeners, but the effect is much more serious to the seedsman and nurseryman, whose business, for the time being, is at a standstill. Those folks who were deceived by the illusory promise of summer have cause to regret their premature action, for in many cases the work of sowing and planting will have to be done again.

Complaints are numerous this season regarding rhubarb going to seed. As many small gardeners are unfamiliar with the appearance of the massive vessel containing the flower, it may be explained that a contributing cause of this undesirable development is the manner in which the roots are left bare of stalks in autumn. Pulling should be moderate and careful, as every leaf removed weakens the plant, and having regard to the crop in the following year it is a good plan to restrict defoliation and allow a few stalks to remain on each root when the season is nearing a close. Another point worth remembering is that the larger the leaves of one season the stronger will be the crown for the next, hence the importance of feeding all through the growing season. Liberal applications of liquid manure have a beneficial effect and bone manure has a wonderful influence on the growth of rhubarb. The stalks are at their best when the leaf has reached full size, and the proper method of pulling is to give the stalk a twist outward and a jerk down at the same time. On the removal of the flower-spikes picking should cease for the season.

"The antirrhinum or snapdragon is undoubtedly on the up-grade at present. It is never likely to cause a *furore* like the sweet pea, but its great usefulness is certain to become more and more appreciated." This quotation is taken from a little volume written by Mr. William Cuthbertson seventeen years ago. It contains two assertions and a prediction. While the former are as true to-day as they were in 1914, the latter has been fulfilled in a remarkable degree. Snapdragons are held in high esteem among all classes of gardeners in Scotland for their easy culture, ornamental effect and long period of bloom, but they are seen at their best in beds of distinct varieties or when massed in a series of self-coloured lines in a border. A charming arrangement consists of using the tall varieties as dot plants in a bed clothed exclusively with the intermediate and dwarf types or, as is the practice in bowling greens and public parks, the tall specimens can be used advantageously as a background to the other two classes, and if harmony of colour is observed in the lay-out either scheme will provide a display that is pleasing to the eye. Several of the new shades are very pretty and offer great possibilities to the artistic gardener. Seedlings that have been hardened off may be planted out towards the end of the month and nice bushy plants can be formed by pinching the main shoot. Snapdragons prefer a sunny situation and require comparatively little moisture after they have been established. Avoid overcrowding by allowing a space of 12ins. between each plant.

Failure on the part of beginners to grow garden beet successfully usually results from early sowing in ground enriched with organic manure. Seed sown before the middle of May has a tendency to produce plants that run prematurely to seed, while the addition of manure shortly before sowing causes the roots to fork and become coarse. The best beet are grown on land that was manured for brassicas or celery in the previous year, and if seaweed is not available a dressing of salt may be added with advantage when the soil is deeply dug some time before sowing. Draw out drills 15ins. apart and 1½ins. deep and drop in two or three seeds at intervals of 6ins. Afterwards thin out to a single plant when the seedlings are large enough to handle. Dobbie's Purple, Nutting's Crimson and Austin's Select Purple are reliable culinary varieties.

The best varieties of the Coltness Gem type of dwarf bedding dahlias for planting out at the end of May or early in June are Coltness Gem, the well known scarlet; Paisley Gem, orange scarlet; Peter Pan, cardinal red; Dinkie, light yellow; Moonbeam, sulphur flushed and edged pink, very pretty; Pink Coltness, rosy pink; and White Gem. Average height 15ins. to 18ins.

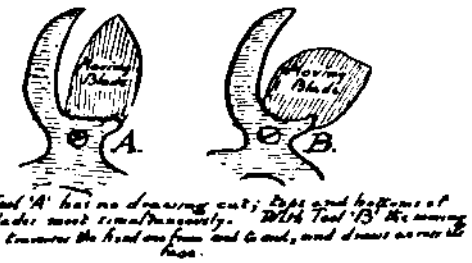
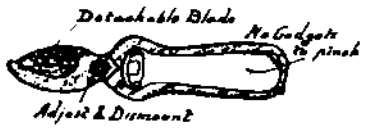
THE AMATEUR AND HIS TOOLS

II.—CUTTING AND EDGING TOOLS.

A COMPLETE "battery" of pruning tools involves an expensive outfit, and the amateur commonly manages very well without many tools which the professional would consider essential. The professional gardener gives first place in his pruning kit to the pruning knife; most amateurs prefer the secateurs. And certainly the secateurs are quicker to work with and, if of a suitable pattern, give quite satisfactory results; also with armed shrubs, such as rose trees, their use involves less damage to the hands by thorns or prickles. The points to look for in



The Tool 'A' has no drawing cut; Edge and bottoms of the blades meet simultaneously. With Tool 'B' the moving blade traverses the fixed one from end to end, and draws across the base.



secateurs are a good "drawing" cut (see figure), high-grade steel in the preferably detachable blade, ease of adjustment and, almost as important, handles which are not liable to pinch the fingers should the blades slip when in use. If the two "legs" of the tool will come apart for sharpening, so much the better. For rose pruning there is much to be said for the pruning scissors, which are cheap to buy, do not pinch the fingers. There is little or no "draw" to their cutting, yet many amateurs rely upon them for all purposes, and by keeping them really sharp, reduce bruising to a minimum.

For branches which are too thick for the scissors or secateurs, reliance has to be placed upon the "grips," pruning saw or bill-hook. The "grips" or lopping shears are really pruning scissors over again, but of larger calibre and equipped with wooden handles from 20ins. to 28ins. long. That they should be of good quality steel goes without saying. They are more easily kept sharp if joined together with a nut, bolt and spring washer rather than riveted. They should be carefully examined for flaws from the junction with the wooden hilts up to the point of leverage, for they sometimes fail in these areas when cutting very hard wood.

The pruning saw should be narrow in the blade and is better single than double-edged. The double-edged tool sometimes cuts where it is not wanted to. The shape shown in the figure is most easily used in the tight places in which this tool is usually needed. With its aid a branch may be cut out clean to the base.

Generally after the "grips" and always after the saw it is necessary to smooth off the stump with a pruning knife or other cutting tool. I say "other cutting tool," because a small sharp bill-hook with only one cutting edge (see figure) is excellent for the purpose and is almost indispensable in other ways. Indeed the amateur with few large shrubs or trees could manage very well with a good pair of secateurs (or scissors) and a light (8in or 9in.) bill-hook of the type mentioned, which, with a little practice, will cut so cleanly that no subsequent trimming is necessary. An alternative to the bill-hook is a light pruning slasher (see figure), used with a *short* handle.

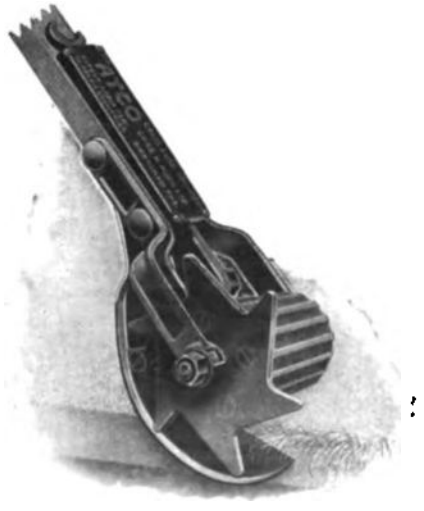
The pruning knife, if you care to use one—and its use *does* make one feel professional—should have a blade very similar in shape to the bill-hook illustrated—that is, with plenty of "draw." The amateur who wishes to try his hand at budding roses, etc., should get a budding knife—by Saynor, and of the shape shown, this being the least clumsy for a beginner.

We have next to consider lawn and hedge tools. In a day when the use of the lawn mower is almost universal, even in the smallest garden, shears are little used for cutting the surface of lawns. Nevertheless, there are gardens where—generally from bad lay-out—steep banks and awkward wall or fence bound corners need hand-snipping. In such case it is best to procure two pairs of shears—one for the hedges and the other for the lawn. It is practically impossible to induce shears used for hedging to cut grass satisfactorily. Pay a fair price for a reliable make, and it is easy to get a good pair of shears. For cutting hedges this tool is sold with a notch towards the base which practically incorporates a lopping shear or "grip." This notch is very useful if not abused. To use it for cutting really thick wood is almost certainly to strain the shears.

Lawn edging machines are quite satisfactory but the gardener still very largely relies on "border" or "edging" shears, of which the most satisfactory pattern is figured. Those with a wheel attachment cost more and weigh more—but the wheel affords many advantages.

While on the subject of lawns and their upkeep, it may be well to say a few words about those very useful tools, the turf plough and the "half-moon," or edging iron. Both are essential if any re-laying is in contemplation—unless, of course, fresh bought turf is introduced to replace—and the last-mentioned tool is needed wherever there is a grass plot. The shape of this most favoured is illustrated, and a "D" handle is preferable to a "T," though the latter is more usual with this particular tool. An edging iron is also useful for keeping the lawn edges and any grass verges neat and tidy.

A selection of cutting tools which the amateur will find of service. Pruning saws, fagging hooks for cutting hedges, turfing irons and weeding forks are here shown.



THE "ATCO" LAWN EDGE TRIMMER.

Worked along the lawn edge, it cuts the overhanging grass clean and tidy.

Though they are by no means edge-tools, this is a convenient place to consider the various devices for extracting weeds from lawns. Two very useful tools are shown, the one lettered "A" being suitable for eradicating plantains, dandelions and similar tap-rooted weeds, and the short-handled one ("B") being just the thing for daisies and other spreading weeds. The well known firm of Barr and Son markets a little all-metal tool—as figured at "C"—which, though it entails getting down to them, will take out cleanly and *permanently* tap-rooted weeds from lawn, border or path, and that with a minimum disturbance to the surface.

From among the collection of cutting and edging tools described here, the amateur should be able to make a selection of good serviceable tools which will last for a number of years if care is taken of them.

MIDLANDER.

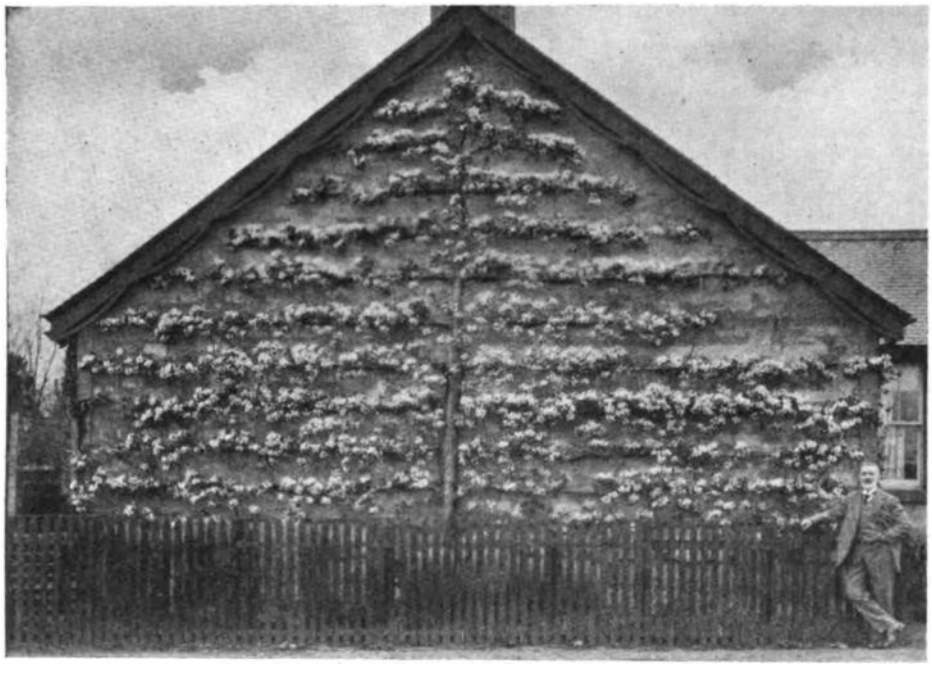
WHAT OUR READERS SAY

A PROLIFIC PEAR TREE.

SIR,—This Jargonelle pear tree, the illustration of which is from a photograph taken at Easter in the garden of Mr. James Thomson, St. Leonards, Ayr, has a remarkable cropping record. Planted in its present position thirty years ago, it has never missed a crop since reaching the fruiting stage, and last year, when all previous yields were surpassed, the number of pears gathered exceeded 3,000. Very light pruning is practised, and stable manure, in the form of a top-dressing, is provided every alternate year. The root system has extended beyond the area of soil enclosed by the wooden paling, made its way underneath a roadway, and, as showing its vigorous growth, the writer was informed that the roots penetrated the cemented joints of a drain-pipe in the adjoining field and ultimately choked the drain, which had to be opened up and cleared in 1926.—JOHN YUILLE.



A JARGONELLE PEAR WITH A REMARKABLE CROPPING RECORD IN AN AYRSHIRE GARDEN.

DELPHINIUMS FROM SEED.

SIR,—Your correspondent (in the issue dated April 16th), would have got a better result by keeping the seed till now and sowing in the open. Plants sown now in the open will overtake those sown in a box last August and will flower this late summer. I have tried both methods repeatedly and the open ground method wins every time. I have also tried sowing as soon as the seed is ripe, but delphinium seed prefers being kept till the spring. Though slugs are extremely numerous they do not prevent the growth of the seedlings.

If your correspondent, however, will try Chase's Continuous Cloches over the drills the seedlings will be quite safe, as the slugs object to crawling over the dry ground. The use of the cloche will also hasten the growth by about a month. It is important never to let the seedlings become crowded.—HUMPHREY SWANN, *Wimbledon, S.W.*19.

ESCHSCHOLTZIAS.

SIR,—I was very interested to read Mr. Balfour's reply to my recent short article on eschscholtzias in your issue dated April 23rd, and I shall hope to try his recommendation as to sowing the seeds in small pots on some future occasion.

As Mr. Balfour will no doubt realise, conditions generally are not nearly so good for annuals with us in the north of Ireland as with our friends living in the south of England, and consequently I am afraid outdoor autumn sowing would hardly prove a success, but seeds are inexpensive and I may be tempted to give his suggestion a trial.

Unfortunately, slugs, etc., are a great source of disappointment here as in many other places, and the seedlings are cleared off in a wholesale manner, while the heavy hail and rain storms experienced so often during April and May prove disastrous in the case of germinating seeds.

In conclusion, I should like to thank Mr. Balfour for his note and hope he will contribute an article on his experiences with other annuals, both hardy and half-hardy.—CECIL M. BAILEY, *Belfast.*

THE USE OF SCARLET FLOWERS IN THE GARDEN.

SIR,—I am rather surprised that scarlet should be considered a difficult colour to deal with in the garden.

Anemone fulgens looks charming with Botryoides cœruleus or Cerastium tomentosum. The scarlet shades of the Ghent azaleas look beautiful when associated with Tiarella cordifolia. The creamy white flowers and pretty leaves veined with red just seem made for the purpose. The scarlet tuberous begonias look particularly well with the grey foliage of Cineraria maritima. The scarlet carnation is perfect with its own grey foliage, but tones beautifully with the intense carmine crimson of the old clove. Scarlet dahlias and scarlet tulips both look at their best when seen with the darkest maroon varieties. Dark tulips, such as Sultan and La Tulipe Noire, are seen to great advantage with scarlet ones, and the same remark applies to sweet peas, while nothing looks better as a background than Cynara Scolymus or French artichoke, with its graceful fern-like grey foliage.

Scarlet-flowered plants, again, associate beautifully with the greenish grey foliage of sea holly. Perhaps Eryngium amethystinum with its blue flower-heads and stems is one of the best for the purpose; or E. Oliverianum. Mention must also be made of Tigridia Pavonia, a gorgeous Mexican flower which associates well with the dark purple bronze foliage of Lobelia fulgens. Scarlets are not difficult to arrange with either light or dark colours, such as those named; but a far greater difficulty is presented to us when attempting to harmonise such a salmon colour as Pelargonium King of Denmark.—H. H. W.

ERRORS IN NAMING.

Geum bulgaricum and Geum × Borisii of gardens.

SIR,—Errors in plant nomenclature in gardens are only too common. Most of us gardeners seem quite willing to accept unquestioningly the name under which we receive a new plant, and once we have fixed the name of the newcomer in our minds we, one and all, seem to be just as reluctant to change it.

For several years now I have harboured in my mind grave uncertainty about the right name of Geum bulgaricum of gardens. I think it was in 1918 that I was introduced to the true plant owning that name, and was not impressed with its garden value, although to the botanical side of my mind it displayed several features of interest and I had glimmers of possibilities of the plant as a potential parent of hybrids.

I think it was while looking at the garden plant some years ago with my friend Clarence Elliott that both of us were struck with some indefinite resemblance to that aristocrat of the highest granitic shingle slides, G. reptans. There was the same voluptuous size, the same sort of decumbent and then upstanding flower stems and the closely ground-hugging habit of the tufts of leaves. Later on I noticed, too, something of the long, soft-awned Strewelpeter effect of the seed heads, very different from that of G. urbanum and the true G. bulgaricum, and I felt I was getting much nearer a possible solution of my enquiry.

Quite lately I got a little more light when looking up another geum in the late Mr. Farrer's monumental work, "The English Rock Garden." "G. bulgaricum" caught my eye, and I re-read what Farrer had to say about this plant, and read, after his whole-hearted condemnation of the true plant, as follows: "But there is a false plant under this name lately come into cultivation, which promises to be magnificent, having fine foliage, not unlike G. reptans, but neater, and fine glowing flowers of flame."

That evening I picked up the Journal of the Royal Horticultural Society, Vol. XXXIX, 1913, and came across the article on Botanising in Bulgaria by the late Captain C. F. Ball.

Writing of the good collection of alpine plants grown in the gardens of the ex-King Ferdinand, and mentioning various outstanding plants, Captain Ball writes: "Geum × Borisii named after Prince Boris, is a natural hybrid between G. bulgaricum and G. reptans. Another hybrid Avens was found on Vitosh, and is supposed to be G. montanum × G. coccineum."

Now, indeed, I feel I have struck a possible solution and would suggest that the false G. bulgaricum of gardens is really the true hybrid Geum × Borisii, and that the other fine hybrid geum we know and value as Geum × Borisii in gardens at the present day is, in reality, the unnamed hybrid Avens mentioned by Captain Ball as the plant from

Digitized by Google

Mount Vitosh, supposed to be the hybrid between GG. montanum and coccineum.

I do not know who introduced either or both of these good and desirable plants, but I would suggest that some accident occurred in transit or on arrival of these plants in England and the labels became misplaced.

I know that in informed circles the valuable Geum × Borisii is considered to be wrongly named, and, personally, I feel now little doubt that that name rightly belongs to the hybrid between G. bulgaricum, the true plant, and G. reptans. If that is so, Geum × Borisii of gardens awaits a new and valid name, and Mr. Kellerer of the Royal Gardens of Sofia might be fitly consulted in regard to that; at all events, it would be well to clear up this confusion and to provide two very good plants for the front of the border or the large rock garden with really valid names.

In concluding, it may be of interest to point out that I have found both these apparent hybrid plants not only fertile but to reproduce themselves perfectly true from seed. Geum × Borisii of gardens seeds freely and regularly, and I have yet to find an offspring among the seedlings that differs from the accepted type. G. bulgaricum of gardens is much less willing to set seeds, and in some seasons I have failed to get seeds even with hand fertilising; but mostly I manage to get a fair crop of seed which germinates fairly evenly and brings plants indistinguishable from the parent plant surely an unusual custom among plants of hybrid origin.—WALTER INGWERSEN.

[If any of our readers have views on this subject we would be most interested to hear from them, as it is a point on which growers of the plants in different parts of the country can give useful testimony as to their nature and behaviour.—ED.]

"THE GARDEN" PHOTOGRAPHIC COMPETITION

The particulars which accompany each photograph should be helpful and suggestive, so that each will be of actual value to the majority of our readers in stimulating further interest in plants and different aspects of gardening. These particulars will be taken into consideration by the Editor in his decisions.

This is an admirable way of growing hydrangeas where facilities are not available for growing them in a greenhouse or in an open border. They provide a most decorative display during the summer months in a corner which would otherwise be drab and dull. Little or no trouble is needed in cultivation. The tubs are wintered in an open shed and gradually exposed to sun and air during May, when all danger of frost is past. The plants themselves are many years old

and are dressed every spring with fresh soil, and a little liquid manure is given at flowering time. The tubs are made from oil casks sawn in half, with drainage holes provided. Small blocks of wood are used for resting the tubs on and metal handles are fixed for ease in moving. The tubs are stained with Solignum, and the rim bands are painted an oak colour to preserve the metal and to look as neutral as possible so as not to detract from the beauty of the blooms.

HYDRANGEAS IN TUBS IN A GARAGE YARD.

This week's guinea photograph, sent in by MISS H. HOBBS, *Liverpool.*

This is a picture of my garden taken last summer when the floral display was at its best. It gives an idea of what may be accomplished in the limited space of a small suburban back garden. Summer flowers, including hollyhocks, phloxes, antirrhinums, iberis, gladioli, pentstemons, all contribute to the scheme, which is not pretentious in any way. Beyond the small flower garden vegetables are grown very successfully.—G. ROGERS, *Twickenham, Middlesex.* Award of 5*s*.

Two years ago I purchased a half-acre plot and built the bungalow shown in the illustration. The front plot I made into a small garden with a central and side flower borders. Along the tradesman's path I planted arabis in small clumps and, as can be seen, the growth has been vigorous, so much so that drastic thinning has been necessary. It makes a neat and easy growing decorative plant for a tradesmen's entrance.—C. CHAPMAN, *Sandridge.* Award of 5*s*.

THE FRUIT AND KITCHEN GARDEN

Treatment of Peaches, Nectarines and Apricots under Glass.

TREES growing under glass are bearing a wonderfully fine crop of fruits. This remark applies to all stone fruits in glass structures. Although the trees are so heavily laden, it will be unwise to overburden them. By far the wisest plan is to be content with a good average crop this year and then there will be all the more likelihood of a good crop again next year. Do not be tempted to apply strong doses of artificial manures to heavily cropped trees. It is too soon to feed freely. A moderate dose of any approved manure will be beneficisl, then, in June, after the stones in the fruits are hardened and the second swelling begins, feed liberally, but judiciously. Every grower wishes to have fine, highly coloured fruits. To obtain such observe the following rules: Thin out peaches finally to one fruit per square foot of wall, or wire space. Nectarines to 9ins. and apricots to 7ins. and 8ins. Really, these numbers constitute a heavy crop. The fruits, if fewer, are of more value because they possess deeper flesh. Some intermediate thinning-out should be done in May, a few surplus and badly placed fruits being removed every week. Then, to obtain that high, attractive colour, expose the fruits to the full sunshine by removing those leaves that are really obstructive. Furthermore, it will be essential to attend to the tying-down of the shoots that are to be retained for fruit-bearing next year; and, in the case of apricots, pinching back certain shoots growing from the spurs. close attention must be given to ventilation, atmospheric moisture and border-watering. The roots should be kept in a consistent state of moisture and the temperature moderate rather than very high. The atmosphere should be buoyant, although it will be absolutely essential to success that damping of floors and syringing of foliage be in the work for each day.—HANTS.

Points in Successful Cabbage Cultivation.

GROUND intended for the cultivation of cabbages, cauliflowers, savoys, etc., should always be deeply dug, preferably two spades in depth, well in advance of the planting season. After digging, apply to the surface some phosphatic fertiliser—basic slag if the soil is heavy, 5lb. to 30 sq. yds.; bone-meal or bone-flour where the soil is light, at the same rate.

Farmyard manure and the phosphatic fertilisers provide the supplementary essential foods which need to be applied by the grower. Lime, if available and applied previous to planting, is not wasted on a cabbage or cauliflower break.

Five factors play an important part in successful cabbage growing:

(1) Watering the bed containing the young plants well in advance of lifting. Lifting the plants carefully with a small fork, so as to preserve the root system.

(2) Plant in deeply cultivated soil rich in nitrogenous food material.

(3) The ground should be firm when planting: therefore, tramp or roll the break, and especially if the soil is light.

(4) Plant deeply: insert the plant so that its lower leaves will be resting on the soil surface when planting is completed.

(5) Firm planting: ram the soil tightly along the full length of the root system, avoiding, of course, undue damage.

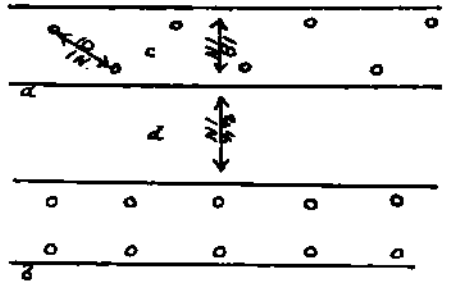
Where a drill is drawn with a hoe about 3ins. or 4ins. wide, and 2ins. deep, and the plants planted in the drill, the sides will afford protection in the early stages. As the cultivation of the soil is progressing during the growing season, this drill becomes filled up and thus earths up the now bare stems. Earthing up to form ridges should be avoided.

When the plants are established, keep the Dutch hoe at work among the plants, at least once a week. This stirring of the soil surface has and does give beneficial results to soil and plants; to say the least, it keeps down weeds and checks undue evaporation of the soil moisture.

Feeding during the growing season with nitrogenous fertilisers—soot, sulphate of ammonia or nitrate of soda, applied in quantities of 1lb. to 30 sq. yds. once or twice during the growing season and hoed in—assists in the production of cabbages we all admire. —J. W. H.

Planting Out Celery.

CELERY is always useful in the dwelling-house. It can be used as a vegetable or as a salad. The plant likes a moist, though not sour, soil in which to grow and it is one of



the most difficult of all vegetables to grow well. In a thin, poor soil the plants will not thrive and I advise all cultivators who have such soils in their gardens to substitute celeriac for long-stick celery. The celeriac, although more suitable for such shallow ground, requires a rich rooting medium, nevertheless. But by forming shallow ridges and the judicious use of organic manures, a double depth of soil can be obtained and suitably enriched. Early white celery may be planted out now; although the pink and red varieties need not be planted before June, the shallow trenches for all may be formed at the same time. Double rows of plants in a trench are more economical than single ones. Only in the case of plants for show purposes need a short, single plant row occupy a trench. The latter, in every case, should be shallow; the top soil is taken out, placed on one side and the subsoil on the opposite. I then return the good soil, mixed with some of the subsoil, to the trench, leaving the remainder of the subsoil for earthing and blanching purposes and thus growing the plants in the best medium. When the manure and soil have been placed in the trench, there should be an open trench about 9ins. deep. This is quite deep enough. The trench should be, for a double row of plants, 18ins. wide and the plants may be planted 10ins. apart. The trench is shown at *a*; at *b*, the wrong way to plant is shown. At *c*, the right way, and at *d*, the distance between the trenches. Do not use weakly plants similar to the one shown at *e*, but such as the one shown at *f*, one with a strong centre *g*, and possessing plenty of fibrous roots. The prepared rooting medium is shown at *h*, manured, and *i*, unmanured. At *j*, *k*, *k*, *l*, respectively, plants and formation of trenches are shown and at *m*, *m*, the section of ground ordinarily dug or trenched. —G. G.

Planting Out the Winter Vegetables.

IT is well to proceed with the planting out of the winter vegetables in May, if the weather is not too dry. June would be, perhaps, a more suitable time for planting if the soil should get well saturated in showery weather. But a spell of drought is a serious obstacle to this sort of work; so it is well to seize the earliest opportunity. It is best to select moderately small plants. Any plants that show a rank growth and much foliage are less suitable for transplanting, especially in dry weather. The plan of cutting off some of the rank leaves has something to commend it, because the larger the leaf surface the greater the quantity of moisture will the plant pass into the air. That is why sturdy and slow-growing seedlings with comparatively small leaves transplant better than seedlings with large flabby leaves.

Savoys, Brussels sprouts, drumhead cabbages, Russian kale, curly greens, or borecole, leeks, celery, etc., may be planted out as soon as possible now.

For plants of the cabbage family, make the soil quite firm before planting, as these plants all require a firm root-hold. The ground should be well manured, for the brassicas are mostly gross feeders. A rich, retentive soil suits them best, plenty of moisture as well as fertility being an essential to a successful growth. Large savoys may be planted 2ft. apart, and dwarf cabbages, kale, etc., about 18ins. to 20ins.

A good artificial to fork into the surface soil to about the same depth as the plants may be made by mixing for each square yard of ground ½oz. sulphate of ammonia, ½oz. muriate of potash, and 1½oz. to 1½oz. superphosphate. If no farmyard manure has been dug into the plots, give quite double these quantities. During the season of growth, give a top-dressing of nitrate of soda, about ½oz. every three or four weeks from June till September.—J. W.

Carrot Fly.

SO insidious a pest has the carrot fly and its maggot become in many parts of the country, that carrots have almost passed the precarious stage into that of the impossible. Yet some growers can raise fine crops and their methods of combating the pest are worthy of consideration. The plan in most cases seems to be, first of all never to leave the soil loose and open; alongside the rows it is thus kept firm by tramping, after hoeing, and thinning is either done in wet weather or the watering can is used to consolidate the

Digitized by Google

soil immediately after. That is not always enough; in addition, the plants must be prevented from casting their "fragrance" into the air. This is successfully done by many by blanketing the fragrance with something of a more penetrating nature. The plants may be sprayed with paraffin oil emulsion (soapy water with a tablespoonful of paraffin per gallon), or sawdust impregnated with paraffin oil (½ pint per gallon of sawdust), or with creosol disinfectant liquid. I have also seen a creosoted wooden rail laid between rows of carrots; or syrup tins partly full of petrol and pierced with a little hole or two, laid here and there in the carrot bed and I have also seen narrow pieces of freshly tarred felt used to keep up the odour. Seedlings should also be stimulated by having a dressing of guano hoed in between the rows. One or more of the above methods is well worth a conscientious trial where pests are usually virulent.—CLYDESDALE.

Broccoli for Michaelmas.

LATE cauliflowers and early broccoli should be grown so that there will not be any break in the supply early in the autumn. If a very dry spell of weather comes in August it is almost impossible to procure really good late cauliflowers. Broccoli will withstand the dry conditions a little better and the curds are not as readily damaged by early frosts. The seeds should be sown in an outside border, not in boxes or frames. The plants should grow steadily and without check from their early seedling stage. Michaelmas White is a very good, reliable variety to grow. On no account should the seeds be sown in soil in which cauliflowers, cabbages or any winter greens have been grown during the previous year. Dig the soil deeply, add some rotted manure if the ground is poor, and sow the seeds very thinly. The object should be to secure strong plants even in their seedling stage. Roughly pulled plants suffer a severe check even if they are transplanted once prior to their final planting. If left undisturbed in their beds until they are lifted for the final planting, they are checked, and checks to growth while they are small means, later on, poor quality heads or curds. Transplant once, in the early part of May, doing the work with the aid of a hand-fork or hand-trowel. Transplant again late in June, in good ground made firm and the best results may be expected.—CHRISTCHURCH.

Parsley.

PARSLEY is a deep rooting plant, hence it is essential that the soil be dug to a depth of two spits in readiness for the plants; a fair to liberal supply of manure should, at the same time, be incorporated in both spits, so that the roots may find nourishment wherever they go. For very earliest supplies seed must be sown under cover, the seedlings pricked out in boxes and finally planted out in March or April. At this time of year, however, sowings may be made directly in the open, in rows 9ins. apart, and the seedlings thinned out in due course. Should wood ashes be available, rake in some the day before planting; otherwise one must rely on a light sprinkling of artificials to stimulate growth during the initial months; it may be noted, too, that steeping of the seed for forty-eight hours materially hastens germination. Growers are strongly urged to choose the best variety which their seedsman offers; the old garnishing kinds, so hardy and prolific it may be granted, are not to be compared to the fine kinds which are now offered. I refrain from naming any one variety because, for kitchen purposes, there is little to choose between such good sorts. I also emphatically urge thin planting, for the produce of individual plants grown with plenty of room is very much superior to that from the "rows" which many cottagers still delight in.—LANARKSHIRE.

GREENHOUSE NOTES

A Good Pot Plant for the Cool House.

Jasminum primulinum.

THIS delightful jasmine was introduced from Yunnan by Messrs. J. Veitch and Sons, and it first flowered at their Coombe Wood Nursery in October, 1901. It is quite hardy, and is often employed as a wall plant, but so far as my experience goes it is a failure outside. At the time of its introduction great things were expected regarding this jasmine, and although it grows freely enough, the flowers are few in number. When, however, it is treated as a pot plant for the cool greenhouse it is indeed a success, and its full beauty is realised. A specimen which I have growing in an 8in. pot, flowered freely during March and early April in a greenhouse from which frosts had been excluded. In general appearance it somewhat resembles J. nudiflorum, both flowers and leaves are larger and, moreover, it is practically evergreen. The bright golden yellow flowers are 1½ins. to 2ins. across, for the most part single, but occasionally semi-double. For the greater part of the year the plants are in the open, the pots being plunged in ashes to keep the roots cool. Here they remain until late autumn, when the plants are placed in a cold greenhouse, where they will be in flower from Christmas onwards. About April or May they are pruned, the long side growths are reduced to half their length and any exhausted shoots removed. If necessary, the plants can be repotted, otherwise it will be desirable to feed the roots during the summer months. When all danger of frosts is past, they should be removed from the greenhouse to a sunny position outside.

If any reader has succeeded in flowering this subject really well in the open, his treatment would be welcomed by many, because J. primulinum is such a fine shrub when more or less covered with its golden blossoms. With me even in stony, hungry soil it makes considerable growth, which fails to ripen, and consequently flowers are sparse. It is readily increased by layers from a specimen in the open, and when rooted excellent examples can be secured for pots.—T. W. B.

Greenhouse Pests.

WITH the increasing power of the sun, greenhouse pests become more troublesome, and it is only by repeated efforts that these can be kept down. The best way of dealing with aphides, leaf-mining maggots etc, is fumigation. Any of the excellent fumigants now so widely advertised may be employed, and always the directions should be carefully followed. When fumigating, allow the house to become dry; then, at nightfall or, at any rate, after the sun has gone down, close all the openings tightly. Place the fumigant near the centre of the house, either on the floor or on the top of a box. Light the material, or the lamp below the fumigating apparatus, and immediately come out, locking the door. Open the house in the morning, and air well before doing any watering. Never allow any plants to be near to the burning fumigant, or damage may be done. Fumigation must not be carried out during the day, as a hot sun will scorch the plants in the tightly closed house. Red spider is often a very serious pest in a greenhouse. This pest flourishes in a very dry atmosphere. Increase the atmospheric moisture by syringing, and keep the house on the cool side. Plants actually attacked may be dusted with flowers of sulphur, and sprinkling with salt water is effective. Ordinary fumigating methods have not proved of much value in dealing with red spider. Mealy bug is a whitish insect about one-twelfth of an inch long, which sucks the sap from plants and causes a great deal of harm. One of the best remedies is a paraffin emulsion formed with 1lb. of soft soap boiled in a quart of water to which, after cooling, half a pint of paraffin is added. One part of this preparation is mixed with 8 parts of water and then syringed on the attacked plants. A drop of methylated spirit on the end of a wire will kill mealy bug, and the spirit forms a penetrating liquid for dropping into the cracks and crevices where the insects live. Abol is an excellent insecticide to use for mealy bug and Gishurst compound is especially to be recommended in the case of vines. All amateurs should make a point of having these materials at hand to check the ravages of many greenhouse pests. Fumigation is also helpful, especially if this can be repeated two or three times at intervals of about ten days. Scale insects will be killed by the application of Bordeaux mixture, Gishurst compound or fir tree oil; but paraffin emulsion is probably almost as effective if this is applied with a stiff brush. Repetition of the measures taken is necessary for scale and, indeed, all insect pests. Eggs which may have been deposited about the house will hatch out and bring further broods along.

Potting and Stopping Plants.

CULTURAL details for the growing of pot plants always include the operation of potting, and very frequently that of "stopping." Both are simple operations in themselves, but unless properly executed more harm than good may result to the plants. Many people think it an easy task to repot a plant, but to do so correctly demands more skill than is generally supposed. Points to bear in mind are: to use clean pots always (if these are new from the kiln they should be soaked in water for half an hour and allowed to dry before use); see that ample and adequate drainage is provided. Use a sweet compost of a mixture suited to the plants it is intended to pot; this compost should be just pleasantly moist. On no account pot plants which are at all dry at the root. When potting on as little check as possible should be given to the plant, therefore take care not to damage the roots. Place the plant centrally in the pot and take care that it is not potted too deeply. With certain soft-wooded subjects roots are emitted from almost any part of the stem, and in these cases deep potting is not harmful, but with hard-wooded plants it may prove fatal. A good rule is to pot to the depth of the old earth mark on the stem. A little of the old surface soil may be carefully pricked away with a pointed stick prior to repotting, thus allowing room for a little new soil. Pot firmly or loosely according to the plants' requirements. Most generally hard-wooded plants require firm potting and soft-wooded plants light potting. After potting keep them in a slightly higher temperature for a few days and shade from bright sunshine. Water with care until they have rooted through the new compost.

"Stopping" is a term employed to denote the removal of the extreme point of a stem or shoot. This is done to encourage branching, and thus a bushy plant is obtained, and also for the purpose of "timing" a plant to bloom by a certain date. It is not advisable to stop a plant and at the same time repot it. If this is done a double check is given to the growth of the plant. A far better plan is to pinch out the ends of the shoots either about ten days prior to potting or about ten days after potting. By this means the check to growth is reduced to a minimum.

THE RHODODENDRON SHOW

MOST visitors to the Rhododendron Society's Show at Vincent Square were amazed at seeing such a wealth of bloom after the devastating week of frost that swept the country. Although it was obvious that a proportion of the exhibits was grown under glass, yet sufficient blooms produced in the open were shown to make it certain that some districts in the south and west at least escaped. From the tales of woe that were heard on all sides, it might be imagined that rhododendrons were the only plants to suffer; that is not the case, in the north east even such hardy shrubs as deutzias, buddleias and philadelphus were cut back to the old wood.

This second Rhododendron Show proves again that there are species and varieties to suit every garden and climate, from the giant-flowered Rh. Nuttallii for the softest corners of the west, to the hardy dwarfs that are admirable for ordinary rock garden planting. The best exhibit staged by the trade was undoubtedly that of Messrs. Gill, who showed a wonderful collection of hybrids and species that succeed best in the mild climate of Cornwall. There were magnificent plants of such fine hybrids as Elspeth, about 8ft. in height, and smothered with trusses of large white flowers, and Ernest Gill. The second prize for the trade was given to Messrs. Wallace, for a good collection of the newer hardy hybrids and a few species, such as the fine Rh. callimorphum, an excellent rose coloured species that does well in colder gardens.

The Amateur's Challenge Cup was presented to Lady Aberconway and The Hon. H. D. McLaren, for an excellent exhibit of cut rhododendrons. In this stand, large sprays of Rh. Augustusii and Rh. yunnanense, the former a good blue-lilac form, the latter pale pink, were most admired, as also was a fine bush of Rh. callimorphum, which has flowered exceptionally well this year.

Most interesting of all for the ordinary amateur was the educational exhibit staged by the Rhododendron Society. This consisted of a collection of dwarf species planted in natural conditions. The planting was so well done that this exhibit should show rock garden enthusiasts the value of these charming dwarf species for average gardens. The range of colour from yellow to rose-lilac and deep blue-lilac, is most attractive; these species are hardy and free flowering and they flower in three years from seed. This new departure, of an educational exhibit, should prove an excellent inducement for the increasing cultivation of rhododendron species in that it shows how the plants should be grown and how they will look in any garden within a very few years.

Perhaps few visitors noticed a hybrid that in course of time will probably provide a new strain of valuable garden rhododendrons. This was a cross between the blue Rh. Augustinii of the triflorum series, that grows to a height of 8ft. or 10ft., and the dwarf blue-lilac Rh. fastigiatum. The colour was an exquisite rich blue-lilac. It is extremely floriferous and quick growing and absolutely hardy. Indiscriminate hybridising of species is not to be encouraged, but the cross mentioned gives us a hybrid that will grow under almost any conditions and stronger and more profuse in flowering than either of the parents.

The Rhododendron Society deserves every praise for their effort to increase the popularity of this most excellent genus. One suggestion can be made and that is that a lecture might be given on each day of the Rhododendron Show. This would prove exceedingly popular with all gardeners who wish to learn something of the newer methods of cultivation.

New Rhododendrons and Other Shrubs.

Apparently in compliment to the Rhododendron Society, Section B of the Floral Committee of the R.H.S. had a special meeting at Vincent Square on May 3rd, the occasion of the second Show of the smaller society, and gave four awards of merit. Two were to beautiful rhododendrons and the others were to a couple of heath-like plants.

Rhododendron Betty, which was also adjudged to be the best hybrid in the Show, was shown by Lady Aberconway and the Hon. H D. McLaren, from their garden at Bodnant, North Wales. It is a large truss of beautiful pink shades. It is a hybrid between Rh. Fortunei and Rh. Thomsonii.

Rh. russatum is one of the dwarf, small-flowered sorts that are valued for the rock garden and for the front of the shrub border. It bears plenty of compact trusses of flowers of a darker blue than the others of its type. It was shown by Mr. A. M. Williams of Werrington Park, Launceston.

The two heath-like shrubs were Cassiope Mertensiana and Gaultheria furiens and, although the latter becomes a goodly sized shrub in favourable conditions, both are most suitable for the rock garden. Cassiope Mertensiana is a dwarf little evergreen, growing only a few inches high. It is also known as Andromeda cupressina; it is a native of California and requires a moist, peaty soil. It makes erect little branches of bright green cypress-like leaves, which cling closely to the shoots, and bears lily-of-the-valley-like flowers. Gaultheria furiens syn. Arbutus furiens, is a stiff growing shrub, bearing dark green, alternate, ovate-lanceolate leaves about 2ins. in length and the flowers, which are also much like those of the lily-of-the-valley, are on short, axillary racemes. Both shrubs were shown by Mr. G. Reuthe.

Some attractive Sprays of Staphylea holocarpa were shown by Mrs. C. M. Whittall, Grayswood Hill, Haslemere. This somewhat rare species from central China has much the same habit as the better known S. colchica and bears longer, semi-pendulous racemes of pale blush flowers, which, as with the other bladder nuts, are followed by inflated fruits.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints—which should not exceed 150 words in length—is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Greenhouse Shading.

As the sun increases in power, the problem of greenhouse shading will again present itself. Something inexpensive, yet which can be removed in dull weather, is difficult to attain. Outside blinds on pulleys are expensive, and get in the way of ventilators. The fact that tomatoes growing on inside of roof gave just the right shade suggested the following plan: Run a wire the length of house inside near the eaves, and another just below the roof ventilators. A cheap muslin costing about 4d. a yard, 30ins. wide, hemmed with tape, on the edge of which are sewn a few rings at intervals can be run along its length. The rings are threaded on the two wires, and two strings attached to draw it backwards and forwards. Such a contrivance on each side of the house should be sufficient, but if not another over path can be put up. —H. P.

An Easy Way of Rooting Cuttings.

To receive a few cuttings of a choice plant, and find, on reaching home, no suitable place in which to root them, is a common occurrence. Bell-glasses, though good, are expensive, and easily broken. A good substitute is to use a 6in. pot, invert a large piece of crock over the hole, and fill it half full or more with sand, allowing the space required by the size of the cuttings; insert the latter, water in, and cover with a piece of clear glass. Place the pot outside under a low wall, in a frame or greenhouse, according to the temperature required. Afford all light possible, without direct sunlight and water enough to keep the cuttings fresh. When rooted, ventilate gradually, until the glass can be dispensed with. Difficult subjects, heaths, etc., can be rooted in this manner.—J. C.

Draining Garden Paths.

On garden paths surfaced with a close-binding gravel, and where the sub-soil is sticky, it is often difficult to run the water off—especially where the middle of the path is rather high. To remedy this, dig a narrow trench, 6ins. to 9ins. deep, according to the width of the path, and 3ins. deeper than the foundation of the path. Fill this up with rough clinkers, and finish off with 2ins. of fine cinders. This may appear incongruous with gravel, but I can assure readers it is not so, and it is a very effective operation, for the water runs quickly off the gravel and soaks away through the clinkers very rapidly.—F. L.

Protection of Valuable Plants, etc., Against Mice, Rabbits and Slugs.

It is dangerous to lay poison for mice and rabbits; one can never tell where vermin will carry it. Plants, etc., may be made distasteful to all these pests by spraying them with paraffin emulsion. This is made by boiling 4oz. of soft soap in a gallon of water, when dissolved, take the pot off the fire and gradually stir a gallon of paraffin into it. Churn the mixture forcibly with the syringe until the whole becomes like a creamy paint. To one part of this add twelve to fifteen parts of cold water. Stir well before using. What is not used bottle off and the emulsion will keep indefinitely until required. See that no free paraffin comes to the top after twenty-four hours. If so, add more soap. Paraffin emulsion should not be used on roses.—W. R. P.

How to Destroy Wire Worms.

This pernicious pest, which lives in the soil for from three to five years, is the larva of a small beetle and is very difficult to destroy. The free use of soot and lime will kill the smaller specimens, while special crops may be protected from their ravages by placing carrots in the soil. These should be examined every other day, not only for wire worms, but also for the click beetle, which is the mature stage of this pest. When taking in pasture for garden ground, skim the turf during late spring, when any wire worms present will be just below the surface; if the turf is stacked in layers and burnt with lime, the pest will be destroyed. When turf is taken off during the winter, the wire worms are deep in the soil and crops usually suffer badly during the first three or four years of cultivation. Soil fumigants are also effective in exterminating wire worms.—C. M.

THE

GARDEN

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2894 Saturday, May 21st, 1927 Price TWOPENCE

THERE is no more favourite Spring flower than the wallflower, beloved of all gardeners. It is not fastidious as regards conditions. It grows equally well in the town garden as in the open, and does not object to full sun or slight shade. Wallflowers are easy to grow in almost any soil and should not be sown too late. The end of this month is a suitable time for sowing so that vigorous-growing bushy plants are obtained for transplanting to their flowering positions in September and October. There are now many fine varieties obtainable in all shades of colour, and the dark crimson, orange and red sorts are worthy of a place in every Spring bedding scheme grown along with forget-me-nots and polyanthus primroses. Very charming colour associations can be attained by grouping wallflowers either with daffodils or tulips, in the former case to act as a succession of bloom and in the latter as a colour groundwork to the tulips. Their uses in the Spring garden could be extended indefinitely.

THE GARDEN

VOL. XCI.—No. 2894. MAY 21, 1927. PRICE TWOPENCE.

NOTES AND COMMENTS

Flowers in the Parks.

THOSE of our readers who reside in and around London, should make a point of visiting the public parks and gardens at this time. The display of spring flowers has never been richer than it is this year, despite the recent spell of hard frost, which was experienced at the end of April and the beginning of this month. The beds and borders of tulips, especially in Hyde Park and St. James's Park are a perfect riot of colour. In one border alone some forty-two thousand bulbs have been planted, part of a gift of fifty-six thousand tulips presented by the Dutch Bulb Growers' Association to our Government. There is no gainsaying that the display will do much to popularise the tulip and extend its cultivation in private gardens and in this way greatly assist our own bulb-growing industry, which is as yet only in its infancy. The border at Victoria Gate, Hyde Park, about one hundred and fifty yards long, shows what may be attained by mass planting of tulips. Naturally, such grandiose schemes cannot be carried out in the small garden, but it indicates a use of the flower which is seldom practised. The bulbs have been planted some 6ins. deep and about 4ins. apart, with the result that weeds have been kept down and the foliage kept clean and free from slug attack. Cottage tulips, Darwins and breeders are grouped in sections and almost every garden tulip of any merit is represented. Every shade of colour is present, from the brightest scarlets through all gradations of pinks, blues and mauves and yellows to the purest white. It is impossible here to mention names, but we advise a visit with a notebook to jot down the names of those varieties which make an appeal, for inclusion in the private garden. It is an excellent way of making a first hand selection of varieties for planting next October and November. Besides the mass planting, one sees them used in other ways, in more formal bedding schemes, combined with other spring flowering subjects. At Kew Gardens, some of the beds in front of the Palm House are particularly attractive and have much to teach the amateur in how to arrange and group flowers to advantage. There one sees beds of the tall May-flowering tulips with wallflowers, notably Cherianthus Allionii, as a groundwork, forget-me-nots, aubrietias as an edging or, more uncommon, the dwarf phlox, or, again, the tall Veronica gentianoides, whose spikes almost reach up to the bells of the tulips. These and many other charming associations are to be seen, and the amateur should make a note of them for future reference. First hand knowledge is always better than relying on advice culled from other sources.

Besides the tulips, a special visit should be paid to St. James's Park to see a novelty in spring borders. Laid out under the direction of Mr. T. Hay, the superintendent, it shows what can be done by using only a few representatives of our favourite spring flowers, including wallflowers, forget-me-nots, polyanthus primroses, pansies and violas, silene, and double daisies. The border is a perfect blaze of colour and worthy of a visit from every flower lover. At Greenwich and Regent's Parks and at Hampton Court the flower gardens are unusually attractive and bring joy of the promise of the future. Gardeners should be in the mood to absorb from every fleeting hour all the pleasure and beauty possible. Never does time gallop so fast as now, when spring slips on into summer and summer as quickly into the days of autumn. Plan a visit to the parks to form a part of your gardening duties.

OUR PHOTOGRAPHIC COMPETITION.

ON page 332 of this week's issue will be found the photographs published in connection with our Photographic Competition. Readers' photographs will be published every week, and we urge all readers who are interested to send along photographs of their gardens during the summer months. Particulars should accompany all photographs so that the illustrations will prove more helpful to the majority of our readers. The rules governing the Competition will be found on page xiv.

Chelsea Show.

THIS year Chelsea Show will be held on Wednesday, Thursday and Friday, May 25th, 26th and 27th. On the first day, Wednesday, May 25th, there will be a private view for Fellows and their friends from 9 a.m. to 12 noon. Only Fellows' and Associates' tickets will admit to the private view, but transferable as well as non-transferable tickets may be used. There will be no admission by payment on Wednesday, May 25th, until 12 noon, when the Show will be opened to the public.

Those who propose to submit new or rare plants to the Committees for certificate should note that the Committees will not meet on the first day of the Show, but at 6 p.m. on the previous evening. All plants, etc., for certificate, must be entered with the Secretaries of the respective Committees by 5.30 p.m. on Tuesday, May 24th. The Committees will receive entries throughout the afternoon.

This Week's Work

For Gardens in the South and Midlands.

Plant water lilies and aquatics and any bog plants.

Sow seeds of wallflowers and other biennials in nursery beds.

Prepare celery trenches.

Mulch and feed roses, and use liquid manure water once weekly.

Keep down green fly and all insect pests on roses and fruit trees by spraying with insecticide.

Prepare beds for summer bedding and start planting bedding plants.

Plant out dahlias and border chrysanthemums and stake at planting time.

Thin all seedlings, and if the weather continues to be dry water them well.

This Week's Work

For Gardens in Scotland and the North.

Plant out stocks, asters, antirrhinums and marigolds.

Stake sweet peas sown in open ground.

Water cauliflowers if the weather is dry.

Sow beetroot in well dug soil that has not recently been manured.

Plant cucumbers in prepared soil in frames.

Prepare ground for dahlias in a sunny position.

Remove seed vessels from rhododendrons as soon as the flowers fade.

Geraniums can be bedded when the weather is fine.

Look out for maggots on rose leaves.

Sow more peas for succession.

Thin out early sowings of turnip, carrot and parsnip.

Digitized by Google

A TINY POOL FOR THE SMALL GARDEN

I.—ITS PLACINGS AND SURROUNDINGS.

MANY an owner of a really small garden would like to own a tiny lily pool, but is deterred from making it by some or all of the following reasons. It is not easy for the amateur to know just how to place or shape the pool so that it shall not appear incongruous in its surroundings; there is the difficulty, for one unacquainted with building construction, of the actual formation work; and, in some cases, there is the uncertainty as to whether a really small piece of water—one can hardly call it a "sheet"—can be kept clean and free from objectionable odour. It is hoped that the following brief notes on pond construction as applicable to the really small garden will enable any keen gardener with the necessary leisure and water supply, to construct and equip satisfactorily his own pool garden.

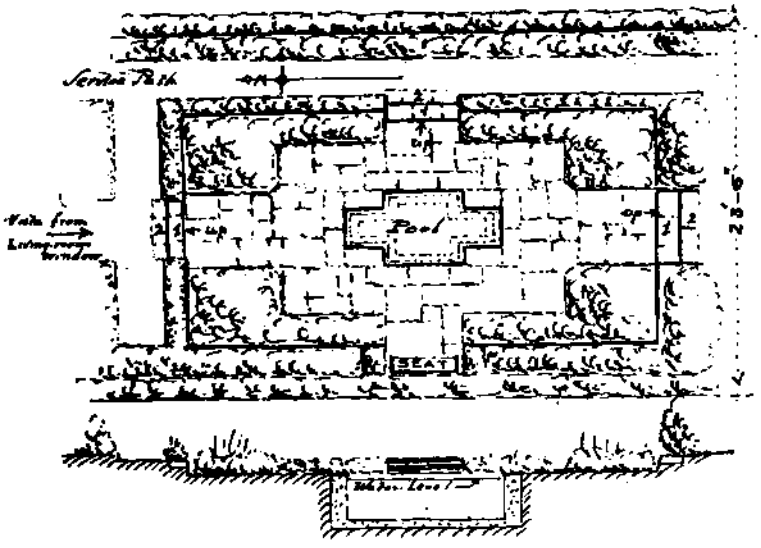

FIG. 1. -Section-

The very small garden is usually a town or suburban one, which means that, providing the necessary rate be paid, a water supply will present little difficulty. Some tap waters are, however, much more suitable for the growth of aquatics than others; the softer the water the better for the purpose in view. All tap waters are cold as they come from the main and in summer, when the plants are in growth, should be admitted to the pool in small doses, lest they lower the temperature of the water too far. From this point of view, too, it is good if the water can traverse a little rill before entering the pool proper; its contact with warm earth or rocks will do much to take the chill from it and also to ensure that it is properly aerated.

This question of the proper quality and warmth of the water is doubly important, because, apart from the fact that a lily pool should grow lilies, upon a proper balance of animal and vegetable life depends the sweetness and clearness of the water; and animal life resents hard, cold water and sudden chills quite as much as does plant growth, so that, in extreme cases, it will be found impossible to keep alive even that hardiest of the water fauna.

In deciding the position of our little pool, we have to take into account the "lie" of the surrounding land and the general style of gardening preferred. If the garden be a sloping one it will generally be best to arrange the pool part way down the slope, thus at once keeping it away from the garden boundary and facilitating the emptying of the pond when this becomes necessary. Under no circumstances should the little pond be in an exposed position or in shade.

Where formality is favoured in the general lay-out, the pool should, of course, be formal in character, and it may find a place on the terrace, if there be one; as a central feature of a little sunk garden, where cold winds will hardly get to chill it; under a terrace — or rather retaining wall; or in association with a pergola or other similar architectural feature. To obtain the maximum effect from our few pailfuls of water, the surface must not be too overgrown with vegetation and we must somehow arrange to get one of the best garden views mirrored upon it.

Where informality is the keynote of the garden, the pond should form the focal point of a little rock garden; and it may be well on one or more sides to arrange for a certain amount of bog planting.

Some ideas for the restful use of water are embodied in the attached figures. Fig. 1 gives a plan of a tiny formal pool—extreme dimensions 10ft. by 5ft.—in a little sunk garden. Good reflections will be obtainable along the length of this, if care be taken with the groupings which should reflect. But it must always be borne in mind that only from a distance do objects at little above water level mirror themselves beneath. In the small garden a considerable object—the house itself, a summer house, tall pergola,

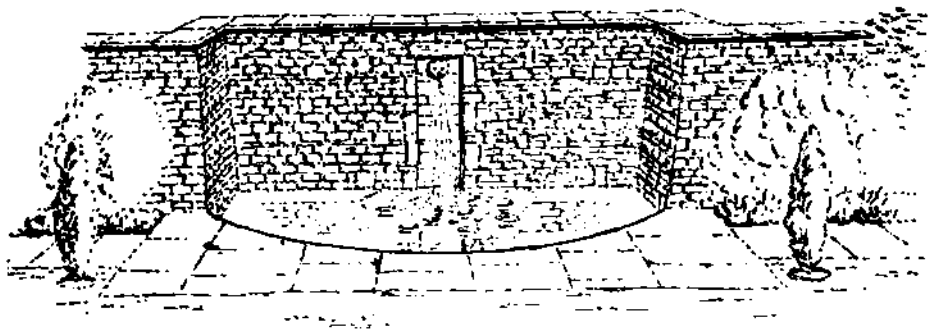

FIG. 2.

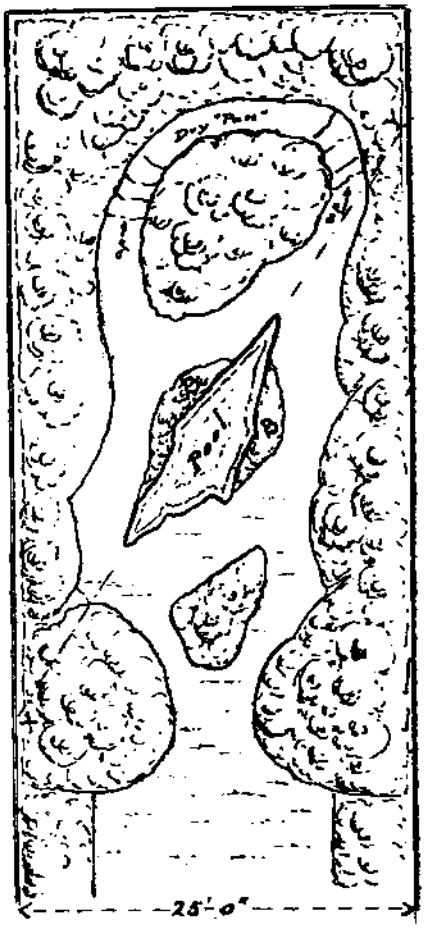

FIG. 3.

birch, poplar tree or something similar is necessary. It will be noted that the extreme width of the garden shown from centre to centre of the bounding (party) hedges is no more than 23ft. 6ins.; and that the sunk garden itself could be accommodated in a garden 3½ft. or 4ft. narrower.

Fig. 4 shows a rough perspective of a simple pergola at the north end of a rectangular garden, partially enclosing an oblong lily tank. As shown this would need a garden 35ft. or 36ft. wide, but the whole might be carried out on a scale which would reduce the total width to 25ft.

The circular tank or dripping well half recessed under a terrace with its domed retaining stonework built over a wooden template, is too complicated for most amateur constructors. The one depicted in Fig. 2, however, presents no constructional difficulties to the amateur mason and would be equally effective. Also, provided it faced south or south-west, it would be a very suitable home for choice water lilies, which the "cave" pattern, generally speaking, is not. This could be carried out to various dimensions, but, as shown, the tank is 10ft. long, the wall recessed 3ft., with a further

Digitized by Google

recessing 18ins. wide by 4ins. deep for the "drip." The wall is 3½ft. above ground level, which again is about 5ins. above that of the water. The extreme width of the tank—that is from front to back—is 6ft. and the curve segmental. Ground level behind the wall might be anything from 9ins. to 18ins. below the coping. The edge of the paving shown should *overhang* the tank to the extent of a couple of inches along its whole length. A little terrace such as this might be arranged either at the house end or the opposite extremity of a little rectangular garden. In gardens of larger size or more diversified in outline, there is usually no difficulty in providing for a tank or terrace—not necessarily, of course, of this proportioning—with a suitable aspect.

The informal pool is best arranged in the little oblong garden strip somewhat as shown in Fig. 3, where the rock and pool garden occupies the end farthest from the house. The rocky mounds must in some way be insulated from and made independent of the enclosing pale or brick fences. This is best done by building dry walls of blast-furnace slag, clinker or other enduring cheap material. In the construction of the grassy paths or ways—for they are of irregular shape—around the pool it is essential that they should be "dished," being lowest near the pool and sloping more noticeably as they near the more or less rocky banks which bound them, and which should show as much diversity of outline and elevation as possible, with little "ravines" and almost flat "estuaries," "bluffs" emphasised by suitable shrubby plants and jagged "cliffs" running for some little distance. It is best to arrange the latter in such a way that they do not run parallel to the turfed ways. These raised surrounds will afford an easy way of disposing of the earth excavated in making the pool. The plots adjoining the pool and marked "B" are intended for bog plants.

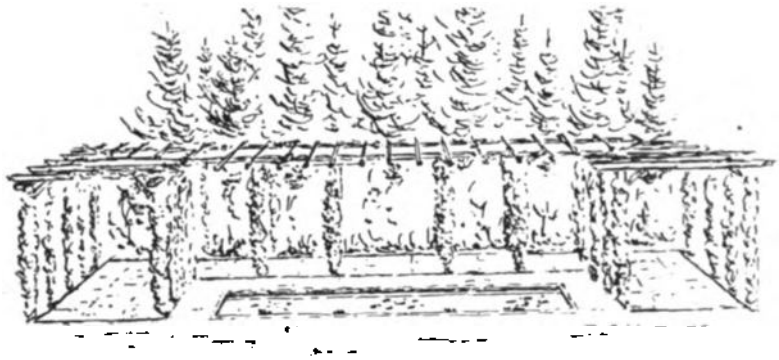

FIG. 4.

In a further article the actual work of construction will be discussed, as well as the plants and "animals" most recommendable for these Lilliputian ponds.

R. V. G. W.

BLUE POPPIES FOR THE ROCKERY—I

Many species of the blue poppies (meconopsis) are now becoming widespread in cultivation, and those amateurs who have not grown them should give them a trial. They are attractive plants and will be found easy to grow if the cultural hints given in this article are carefully followed. A description of some of the best species for the amateur to grow will be given in next week's issue.

THE poppyworts, or Himalayan poppies—often called *blue* poppies, although blue is by no means the only colour found among them—are comparatively new aspirants to garden honours; nevertheless, they are rapidly gaining in favour as subjects for the rock garden, where they add just that species of grace and form denied to the more strictly alpine cliff plants, which crouch and cower among the rocks. Year by year, thanks to the discovery of some successful mode of treatment another of the fifty odd known species is brought into fairly general cultivation, and there can be few gardens indeed where one or other of the dozen established species, given a little attention, will not thrive.

Whereas a decade ago the poppyworts were regarded as rarities, if not curiosities, most hardy plant nurseries now catalogue six or eight species. They can be bought in shillings packets of seeds, and young plants may be had for two shillings or half a crown. Given a few plants to start with, a stock can quickly be raised from seed.

They are annual, biennial or perennial plants; but the majority are biennial. If they seed themselves—and several do that—this is no disadvantage; in any event, they are easily raised from seed if certain simple directions are followed.

Raising from Seed.

Meconopsis seeds do not keep a long time, and should be sown as soon as possible, preferably in the late winter or very early spring; if the sowing is left till the summer, they will probably not germinate till the following year. A light porous soil is essential, one composed of about equal parts of loam, shredded peat and sand, giving the best results; and the seeds may be sown fairly thickly in pots or boxes. There is no need to use heat, an ordinary greenhouse, or even a frame, being all that is required; and seed sown in January or February should germinate in a month or six weeks, though sometimes they lie in the soil for a year before germinating.

Generally speaking, the seeds germinate freely; the mortality comes later, among the seedlings, which damp off. As soon as the first adult leaf appears, following the cotyledons—*i.e.*, about six weeks after germination—the young plants may be pricked off into pans, where they will remain till the following year; then in the spring they may be planted out in the rock garden.

Planting Out.

As already suggested, the poppyworts are admirably suited to the rock garden; they do equally well in a bed against a wall. Being rather precious, it is perhaps flippant to say they ought to be massed for effect; most of us have not a sufficient number of them for that, and mass production is still a dream. But that undoubtedly is the ideal.

The species, however, ought not to be mixed up anyhow like a crossword puzzle. Those already in cultivation are extremely diverse not only in size, but in habit and flower colour; they include representatives of all the chief natural groups into which the species fall. They should be grown in clumps, or the bigger ones may be scattered singly about the rock garden.

ONE OF THE BEST OF THE POPPIES, MECONOPSIS INTEGRIFOLIA.

In most species, whether biennial or perennial, the leaves die back in the winter; but in a few species the crown persists to send up a tall central stem the following year.

Soil and Situation.

The important thing to remember is that every species, whether biennial or perennial ultimately develops a long tap-root, and that, in order to do so unhampered, it needs a rather light soil of considerable depth, thoroughly drained below. Stagnant water at the roots is anathema—the poppyworts are not bog plants. A clear depth of at least 3ft., preferably 4ft., should be allowed, the best results being obtained with a mixture of loam and fine gravel, or sand, about half and half. Some species thrive in calcareous soils, though not one is *confined* to limestone, and since these do quite as well without it, it is better to avoid lime if possible; some species reject it altogether. A peaty soil in which rhododendrons will grow also suits meconopsis.

In its first year the plant builds up a stout crown, and in the second year it squanders a large amount of material on the bulky inflorescence; yet to see some of these plants growing in the hungry alpine gravel, one would think that they lived entirely on air and water. The truth is they take up a considerable quantity of food in liquid form, owing to the constant flow, from rain and melting snow, just below the surface, down the steep faces on which they thrive. There is a perpetual circulation through the plant, and the hollow stem will usually be found full of liquid; thus it is advisable to grow them at the foot of the rock garden, or on a bank.

Though scarcely sun-worshippers, most poppyworts enjoy the open, growing in meadows, or on the alpine moorland, or on screes. A few, such as M. Wallichii, prefer half shade; while M. Baileyi is actually a woodland plant.

Slugs seem to have a passion for some species, and are very destructive to the young plants.

F. KINGDON WARD.

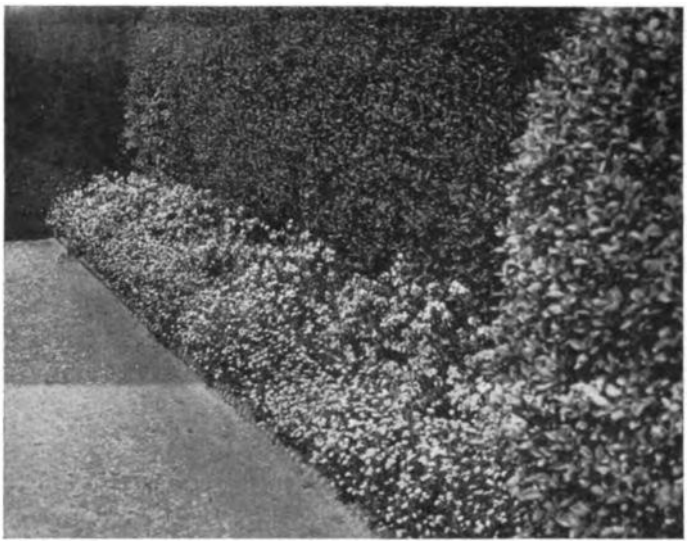
WALLFLOWERS FOR PRESENT SOWING

IT may seem early to be thinking of next year's wallflowers, before even the present year's plants are past their prime, but there can be no doubt that the finest show is obtained from seed sown at the present time. Wallflowers are truly gorgeous bedding plants, yet for all that are seldom grown to their fullest perfection except by the seasoned gardener. Their very ease of cultivation militates against them, for the novice is apt to think that sowings can be made at any time during summer, and that the seedlings can be transplanted at any time, nd into any odd corner.

For really good results, seed should be sown very thinly in drills on a sunny border during the next week or so. The seedlings will grow all the more hardily if the seed bed be given a light dressing of powdered lime previous to sowing, but in no circumstances should the ground be heavily manured. As soon as the seedlings have reached a height of 2ins. to 3ins., they should be transplanted to nursery beds in a sunny part of the garden, ground vacated by early potatoes being very suitable for the purpose. In these beds, at least 6ins. must be allowed between each plant, and 9ins. between the rows, while care should be taken to plant the seedlings quite firmly, thus encouraging sturdy, short-jointd growth. Little further attention is necessary beyond frequent and regular hoeings, which will go far towards maintaining the soil in sweet, yet moist condition, besides keeping the weeds in check. The final planting-out should take place in autumn, and here again moderately rich soil and very firm planting will give the best results.

As regards varieties to grow, it may be said that the old blood-red and rich yellow sorts are very effective, especially when grown together. There are, however, a number of more modern sorts, with a wide range of bright colours, and these will make a gorgeous show planted in separate beds of named varieties. A selection from the following will please the most critical, and it cannot be too strongly urged that at least a few should be tried. Purple Queen, a colour which is very telling, but should be used sparingly, perhaps the finest effects being produced when growing with a lemon yellow sort, such as Faerie Queen or Primrose Monarch. Fire King is undoubtedly the most brilliant of all wallflowers, with large flowers of the most vivid shade of orange. It should be given a sheltered position, for the young buds are apt to be crippled by frost or cold, drying winds. Vulcan is a widely grown variety, with rich crimson flowers of wondrous velvety substance, and for those who prefer an even deeper shade, there is the splendid Sutton's Darkest of All. As a contrast to the preceding may be mentioned Ivory White, with blossoms of that shade. This is rather a delicate species and more suited to frame culture in its early stages, though quite hardy enough to withstand average winter conditions outdoors when it has reached a size suitable for bedding out. Eastern Queen is unique, in that the flowers open apricot, passing off to rosy pink as they age. There are also dwarf wallflowers exhibiting a wide range of colour, and these will be found useful for ribbon borders, also for edging beds of taller growing sorts. The scope for carrying out novel colour schemes in the spring garden with these wallflowers is practically unlimited. Tulips may be grown with them in the same bed, and by choosing suitable May-flowering sorts an exceedingly bright show may be had. Another good plan is to grow early-flowering daffodils among the wallflowers, for in this way the beds are rendered attractive from early March until the middle or end of May. Another race of wallflowers is the early Parisian strain. From a sowing made in June, blossom production will commence tn autumn, and keep on intermittently throughout the winter, varying of course according to weather conditions. With the advent of spring, they burst forth in full glory, thus anticipating by some weeks the flowering period of the commoner forms of Cheiranthus Cheiri.



A BORDER OF WALLFLOWERS WITH AN EDGING OF FORGET-ME-NOTS LOOKS WELL IN FRONT OF A LIGHT EVERGREEN HEDGE.

Besides the single wallflowers noted above, there are also double sorts which are easily raised from seed. The spikes of blossom resemble those of some very fine early-flowering stock, except in colour, rich shades of yellow, bronze and red being the prevailing hues in this class. Rather different is C. Harpur Crewe, with a profusion of tiny yellow button flowers during spring. This species is of true perennial nature, and seems more at home in the hardy border than in flower beds. Stock may be increased by cuttings inserted in beds of sandy soil in the cold frame during early autumn. The young plants should be wintered in the cold frame, being planted out in early April if weather conditions are favourable.

There are several exceedingly showy relatives of the wallflowers, but these are not widely grown, though it is true that the Siberian wallflower is coming into marked favour. All the species noted below may be raised from seed, treatment being the same as for C. Cheiri and its varieties. Cheiranthus alpinus (syn. erysimum) is a gem for the rock garden and for naturalising on old walls or similar positions. In these places, self sown seedlings will spring up freely, forming charming natural groups if left unmolested. The fragrant lemon yellow flowers are produced freely and over quite a long period. C. Allionii, the gorgeous Siberian wallflower, needs little introduction. Suffice it to say that the plant is remarkably free-flowering and the blossoms of a really satisfying shade of orange. Seed should be sown rather later than the common wallflower, otherwise there is danger of the plants flowering prematurely in autumn. Erysimum Perofskianum deserves mention, for it is an annual form of the preceding. Seed sown in early spring will make a brave show during the first year, while for spring blossom, seed may be sown in August. E. linifolium is another good member of this family, with numerous heads of clear mauve flowers during May and June. This species was admirably illustrated in the April 9th issue, to which readers may be referred. Cheiranthus mutabilis, with flowers varying from cream to purple, should certainly be tried. It makes an attractive bedding plant, flowering during May and June and growing about 12ins. high. C. Marshallii is another valuable sort for bedding purposes, also for edging sunny borders; the fragrant blossoms are of a deep shade of orange, and tone well with that rather difficult magenta form of aubrietia, which clashes with almost every shade but orange.

B. D. S.

Rake the surface soil before sowing.

The seed drills should be about 1in. deep, and 9 to 12ins. apart.

Covering the seeds with fine soil.

A MODERN VARIETY OF MIMULUS.

PRACTICAL PARAGRAPHS ON POPULAR PLANTS

WE give below a series of practical paragraphs on popular plants which are intended mainly for the help of beginners and amateurs. Some of them are known by their old-fashioned names, and have long been loved both for their beauty in the borders and for their worth as flowers for cutting. All are easy plants to grow and will give long and useful service in the garden.

THE FRAGRANT MIGNONETTE.

Mimulus (Musk Monkey Flower). APART from the common musk withi ts yellow blossoms (the fragrance from which seems to have departed) there are other members of the family which serve a useful purpose in the garden and are as hardy as other perennials. Some of them have spotted brown and crimson flowers, others scarlet and yellow. They grow best if planted in moist, shady places, or even near to water. They thrive in rich soil full of humus, as, for instance, leaf-mould and old vegetable refuse. Propagation is from cuttings taken in spring and struck in sandy soil, from seed sown in warmth in March, April or May in pans of light soil, and by root division in spring.

Iberis (Candytuft). THIS is an important and popular family, the perennial sorts filling positions in the rock garden, on banks and almost any place in the garden where their procumbent habit can be considered, and the annual forms being of much service in bedding-out arrangements, for edging purposes and the like. The perennial sorts are very hardy, need only ordinary soil, and reward the grower in spring with masses of snow white flowers. Planting time is March. Propagation is by cuttings taken near a joint and inserted in sandy soil either in the open ground or in a pan after they have done blooming by dividing the plants, and from seed also, which can be sown in a cold frame in spring. Annual varieties may be sown in the garden in April or May where they are wanted to bloom. Some are only about 6ins. in height and the tallest about 12ins. A sunny position is the best for them.

Lupins. OF the three forms of lupin, herbaceous, tree and annual, the first has come into such prominence within the last ten or fifteen years that no representative hardy flower border is considered complete without some of them, They are old-time garden flowering plants, the revival of interest in which is all to the good. Generally speaking, they give the best results when planted in light and well drained soil, helped with decayed manure and given a sunny position. A cold, heavy soil is unsuitable for them. They vary in height from 4ft. to 5ft. and are usually at their best in June and during July. They can be increased either by root division in March, or from seed sown in the open ground in light soil, in April or May.

THE PERENNIAL CANDYTUFT (IBERIS) IS A FINE SUBJECT FOR PLANTING IN BOLD CLUMPS IN THE ROCK GARDEN, WHILE THE ANNUAL FORMS ARE ADMIRABLE FOR EDGING BEDS AND BORDERS.

Mignonette. NO annual noted for its sweet fragrance is more popular than mignonette. It is found everywhere, yet although its requirements are simple, it is often indifferently grown owing to its being overcrowded in the bed. As is known, seed may be sown in succession from April onwards to have a good supply of spikes for cutting all through the summer. Soil for it should be rich, light, and always the position selected be sunny. A compost made up of good garden soil with a little leaf-mould and decayed manure worked in and the bed made quite firm—almost hard—suits mignonette. Seeds ought to be sown very thinly and thinning be resorted to very radically when it is remembered that a well grown plant will occupy a foot, and yield an immense number of spikes stronger in every way than plants congested. One has but to take a lesson from a stray seed dropped in a border and growing in isolation. When the young plants are making headway a dusting of soot and wood ashes about the bed will help them and keep at bay the fly which in certain seasons attacks young plants. One may have quite dwarf sorts to giants of nearly 2ft.

Virginia Stock. A VERY simple, easily grown and popular annual much used for edgings to beds and borders, and a general favourite in town and suburban gardens. It will thrive often in the poorest soil, and needs only to be sown very thinly where it is wanted to bloom. If sown in April or May, it will commence to flower in June. It is useful also for sowing in pockets in the rock garden, as it only grows about 6ins. Colours: crimson, red, white and yellow. Some of the yellow flowered varieties are tinged with green. A capital annual for a town garden.

THE BUSY MAN'S PAGE

Hints on Bedding Out.

WHEN planting out the summer "bedders," it is well to note whether the various plants do best in a comparatively poor or rich soil. For instance, heliotrope and ageratum will grow well in a good medium class soil, but begonias and dahlias require a very rich soil if they are to be grown to perfection. Only well rotted manure should be used and it should be well mixed with the soil. In any case, it is inadvisable to let manure come in close contact with the roots of plants. A slight layer of soil should lie between the manure and the roots. Flowers which naturally need less moisture than certain of those plants which produce a profusion of foliage, also need less manure. French marigolds are best when grown on a somewhat poor soil, but the African varieties require a moderately rich soil.

Geraniums bloom best when the soil is rather poor, and not too wet, in fact, a dry, warm, sandy border suits these favourite bedders admirably. Fuchsias on the other hand make a lovely display if the soil is quite rich. Thus it will be seen that quite a collection of different qualities of soil will be required when bedding out. It is well to have a quantity of fine silver sand, some well decayed turf and leaf-mould, and a certain amount of suitable manure at hand. Good loam or garden soil will form the chief material in which to place the bedders. Watering will be necessary if the weather is dry. After a day of hot sun, a sprinkling of water overhead in the evening will be very beneficial, especially for such plants as asters, stocks, violas, dahlias, pansies, chrysanthemums, etc. When planting out give one good soaking of water in the evening. This is better than frequent sprinklings, if the soil has become very dry.

An Easy Way of Performing a Difficult Task.

EVERYONE who possesses a grass plot or path will agree that the greatest trouble connected with such is keeping the edges in a well trimmed condition, especially alongside paths and garden beds and borders.

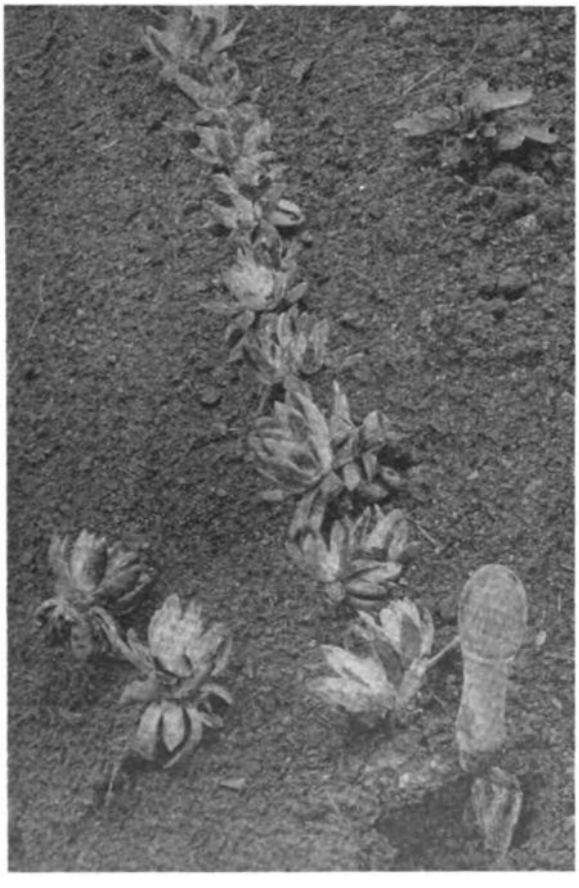
There are several verge-trimmers that do the work of edge cutting very efficiently where there exists a very long verge to be kept in order; in the ordinary home garden, however, such tools are unnecessary. The shears is the normal tool to use in this connection—the verge shears in particular, and a useful development in the latter is seen in the provision of a wheel at the corner of the blade nearest the ground, so that when cutting the verge the wheel rests upon and runs along the path or border, keeping the blades of the shears steadily in position and eliminating the laborious part of the operation by taking all the weight of the shears. This tool will be found especially useful in trimming the edges of circular beds, as well as scalloped borders, awkward corners, around the roots of shrubs and trees, and around the bases of garden seats and statues.

A LABOUR-SAVING TOOL FOR TRIMMING THE EDGES OF THE LAWN.

An Attractive Edging Plant.

ALTHOUGH succulents are not employed in bedding schemes these days to the extent they were when carpet bedding was the vogue, one still finds gardens here and there where use is made of plants of this kind, and of those so employed probably the most commonly met with are the echeverias. Somewhat similar to the houseleeks in appearance, these have a compact rosette form of growth varying slightly in colour according to the species. One of the most useful for carpeting or for edging beds or borders is Echeveria secunda and its variety glauca, the grey or bluish green foliage and orange crimson flowers of these showing to advantage when utilised in this way.

In the accompaning illustration showing the method of planting a row of these, it will be noticed that the hole taken out is large enough to accommodate the roots easily, so that when planting is completed the lower leaves are close to the ground, which not only helps to keep the roots cool but lessens the chances of the neatness of the edging being marred by an odd plant sticking up here and there above the level of the others, and a much more finished and better appearance is obtained if the plants are put in fairly close to each other and practically no soil can be seen. The echeverias are by no means fastidious as to soil and situation, but the addition of some old lime rubble to the soil is recommended.



PLANTING ECHEVERIAS AS AN EDGING.
The plants should be placed about three to four inches apart. When established, this edging is most decorative.

Potting on Young Plants.

YOUNG plants which are being grown on in small pots with the intention of removal into others later on should not be allowed to get really potbound. This condition will certainly check their growth, and a common result is a premature blooming. The best time to give young plants a move is when the roots are showing well on the outside of the ball of soil. This is readily ascertained by gently tapping the plants out of the pots. It is a mistake to think that one is saving time and trouble by moving, say, a plant in a 4in. pot into one that is 8ins. in diameter. The large amount of spare soil which has to be placed around the plant will surely become sour from frequent waterings, as, of course, the moisture cannot be restricted to those parts where the roots happen to be growing. The proper method is to move the plant into a pot which, at most, is no more than two sizes larger than the one in which it happens to be growing.

Mulching and Feeding Roses.

MULCHING rose-beds with decayed manure during the early summer is highly beneficial to the plants and brings its reward in the increased quantity of bloom produced, the greater vigour of the plants, and their greater resistance to attacks of insect and fungoid pests and diseases. In the case of newly planted beds it is practically essential; while in very hot summers it frequently prevents the roses from collapsing and reduces the necessity for artificial watering to a minimum.

Good rich manure from the piggery or cow-sheds is to be preferred, except on the very heaviest soils, where well rotted stable manure may be substituted. The nourishment is then gradually washed down to the roots, which are kept cool and moist even in the hottest weather. A little fine soil sprinkled over the mulch will prevent any unsightly appearance. The best stimulant to apply to roses is undoubtedly liquid farmyard manure; this should only be applied when the ground is reasonably moist, and should be diluted until it is no darker in colour than weak tea. Should the ground be very dry, a good soaking with clear water should be given some hours before the manure water is applied.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Hardy Ferns.

MOST people have a preference for plants which flower, but there is really just as much interest and beauty among the flowerless ferns. Ferns have many uses. As pot plants for home decoration they are first favourites. For odd shady corners of the garden they are most useful, and the cut fronds are frequently in demand for using with flowers in vases. Perhaps this is why so many people try to dig up the ferns which they find when away on holiday and take them home. I should like to discourage readers of THE GARDEN from doing this. Digging up ferns in this manner is seldom very satisfactory.

Kinds to Grow.

There are a very large number of species which vary considerably as to hardiness, it is well to exercise care in selection. There are thirty-eight species of ferns which are found wild in Great Britain, and which should therefore prove hardy under cultivation. These include hart's tongue, parsley fern, hard fern, maidenhair, wallrue, spleenwort, lady fern, prickly shield fern, male fern and polypody. These are all very beautiful, and no doubt most people possess one or more of these ferns. Nurserymen now have new varieties of many of these, but, unlike the flowering plants, ferns are not much altered by the hybridist.

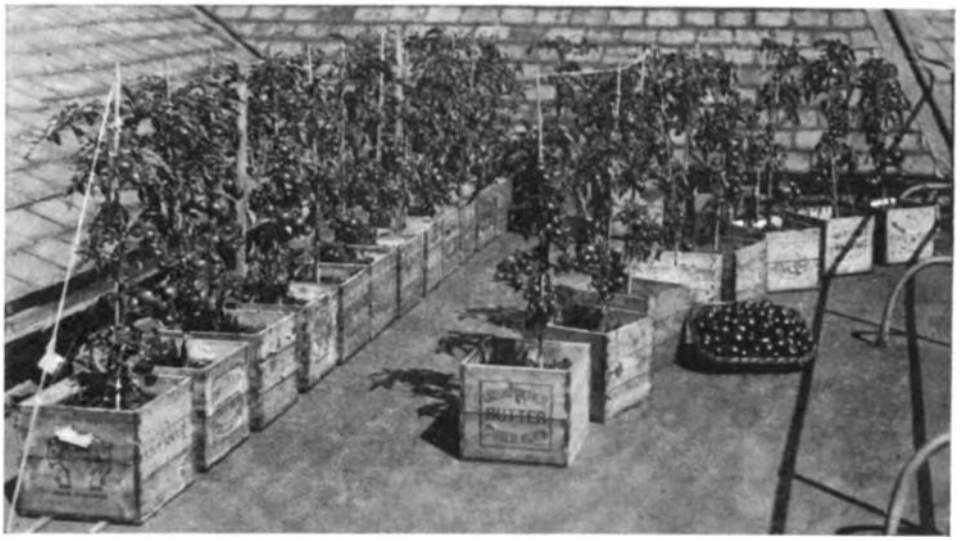
Indoor Varieties.

Of the many half-hardy ferns which are suitable for cultivating indoors, one of the most useful is Pteris cretica, cousin to the common bracken, of which there are many varieties. Adiantum Capillus-veneris (maidenhair) and Asplenium bulbiferum are two others suitable for growing in pots, but the maidenhair fern will not grow if gas is burnt in the room.

Leaf Mould for Ferns.

Most ferns like plenty of decayed leaves mixed with the soil, in addition to sand. A useful compost is made by mixing leafmould, loam and sand in equal proportions. Some varieties, *e.g.*, Blechnum spicant and Adiantum pedatum, like lime rubble in the soil. Clean drainage is essential to all, for although ferns like moisture, stagnation is fatal. Pot ferns should always have broken crocks at the bottom of the pot. Broken charcoal and lime rubble mixed in the soil used for potting maidenhair ferns will keep them healthy.

Ferns should never be allowed to become dry at the roots. This is the most frequent cause of failure in their cultivation. Nor should the leaves be forgotten. Submerge both the pot and leaves in a pail of water, and then allow to stand in the sink to drain before replacing in the room.



A FINE CROP OF TOMATOES GROWN IN BOXES ON A TOWN ROOF GARDEN.

A Fruit for the Small Garden—The Tomato.

ABOUT the first week in June the plants can safely be put outside in their permanent quarters. For those who are not fortunate in possessing a greenhouse or frame hot-bed to raise their own plants a selection of plants should be made from a reputed nurseryman. There are several varieties of tomatoes that are specially suitable for outdoor cultivation, a few of the best being Earliest of All, Open Air, A.1, Maincrop, Eclipse and Sunrise. A south wall or paling fence, is an ideal position for training the plants. Such a position retains the heat of the sun well into the night, so that the plants do not get the extremes of temperature as usually obtain in an open position, as for instance, on an allotment.

The sunniest spot in the garden should be chosen. The plants should be placed 18ins. to 2ft. apart in a row, and the same distance allowed between if more than one row is planted. The rows should run north and south. The tomato will grow in ordinary soil, provided it is deeply cultivated, well drained and friable. Heavy clay soils can be made friable by the addition of coarse sand, leaf soil, charred refuse and old lime rubble. Fresh manure should be avoided at planting time, otherwise strong leaf and branch growth will be encouraged at the expense of fruiting. The plants should be well firmed in when planting. A stout stake, 4ft. long, should be placed to each plant.

During the growth of the plants, all side shoots should be pinched out, retaining the single stem or leader, and tying it to the stake from time to time as required. When the plants have reached the top of the stake, the growing point of the leader should be pinched out so as to divert the energy of the plant into the swelling up of the fruit. After the fruit is set, a mulch of stable manure should be applied on the surface soil around the plants. Failing stable manure, decayed vegetable matter, such as grass clippings, or leaf soil, can be substituted, and the plants fed with a little chemical manure made up as follows: 3 parts superphosphate of lime, 1 part sulphate of potash, mixed together and applied at the rate of 1oz. to the square yard. The application should be made fortnightly and alternated with soot water. Moisten the soil first, apply the respective manures and water well in. A little ground lime should be applied in the early stages of growth. As the fruits swell up, they should be exposed to the light by shortening an occasional fully matured leaf half-way, but this defoliation must not be done ruthlessly, otherwise the cultivator may court disaster.

A CHOICE COLLECTION OF HARDY FERNS IN A TOWN GARDEN.

Digitized by Google

WORK IN THE FLOWER GARDEN

A Fine Shrub for a Wall.

FREMONTIA CALIFORNICA is a shrub well worth growing, on account of the prolific crops of large golden yellow flowers it bears, of about 2½ins. in width. I think it would be more often seen if it were not for its reputation of supposed tenderness; but I am sure it is much hardier than is generally credited. A specimen here (7ft. in height by 5½ins. in breadth) growing on a wall, with a south aspect, and well protected from the north, has come safely through the rigours of two winters. All the protection afforded was by a few thin spruce branches placed over it in severe frost. In the position the plant occupies here, it comes into flower towards the end of May and continues giving crops of flowers until October. If it were not for the cold and want of sunshine, it would go on flowering, as many buds remain unopened. Since it was first planted, it has made vigorous and almost rampant growth in midsummer, which frequently required tying in or cutting back. Good loam with a liberal addition of half-decayed leaves and some peat, which helps very much to retain the moisture, apparently meet its requirements and keep it in vigorous and robust health which enables it to come through severe winter weather without any bad effects.

Abelia chinensis and A. longituba have occupied an almost similar position as the fremontia, with almost the identically same treatment as to soil and spruce branch protection during hard frosts. Both plants have come through the winters unscathed, with the exception of a few half-developed on the points, as these plants appear to insist on growing all winter.

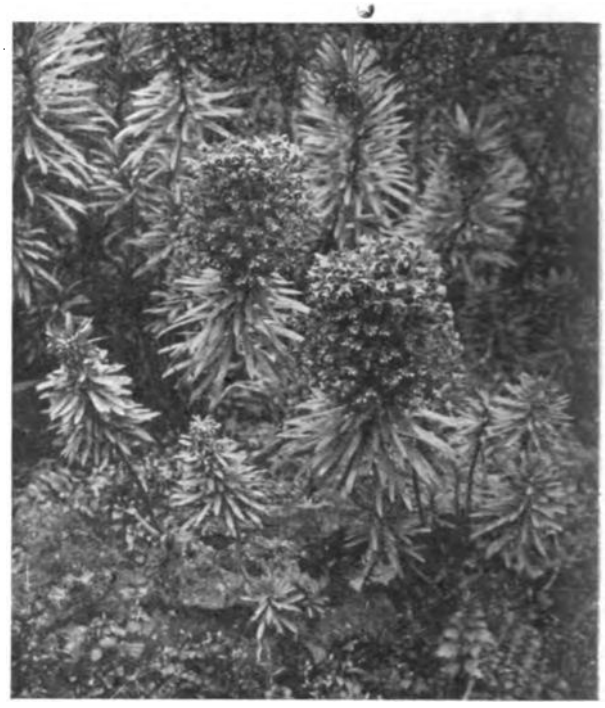
To come through the trial of the prolonged Kincardineshire winters has been a fair test of the hardihood of the fremontia and the abelias (more so than London, as is often quoted); and it would be fair to assume that they may be planted anywhere if given wall protection and soil to suit them and watering attended to in dry weather. — W. G., *Kincardineshire.*

A Quick-Growing Clematis.

Clematis Vitalba.

THERE are often about gardens places more or less unsightly, or that would be so if left to themselves. But there is no need for this when they can be so easily covered by some quick-growing plant. The stoke-hole in a garden yard could only be covered with corrugated iron; but now, instead of being an ugly object, always offending the eye, it has a gracious covering of the wild clematis, good in leaf, flower and fruit for more than half the year. Even in winter, when it is bare of leaves, the quantity of stem, spreading and interlacing, completely hides the iron roof. It can also be most effectively used for covering a rough fence. Each flower of the many in the cluster becomes a tightly packed head of seed, and each seed is furnished with a feathery awn about an inch long and curved, so forming a sort of loose mop. If branches of seed are brought indoors and dried for a few days, the tiny feathers, which out of doors lie folded along the awn, spread out in a beautiful way and the branches can be used for room ornament, though it is well not to keep them too long, as they easily catch dust and only too readily retain it. On the chalk hills, where the plant grows in profusion, festooning the hedges and rambling over thorny brakes and broken ground and the edges of old chalk pits, it abundantly justifies the good old name of Traveller's Joy.—G. J.

AN UNSIGHTLY CORNER BEAUTIFIED BY THE QUICK-GROWING TRAVELLER'S JOY (CLEMATIS VITALBA).



THE CURIOUSLY FORMED FLOWERS OF E. CHARACIAS.

An Attractive Spurge.

THIS interesting plant, Euphorbia Characias, comes among the few early-blooming plants of rather large size, forming bushes about 2½ft. high and through. It has much the general appearance, though all on a smaller scale, of the handsome E. Wulfenii, though the bloom is differently coloured and not so effective. In E. Wulfenii the great round-topped flower-heads may be as much as 15ins. high and 8ins. or 9ins. through; while those of Characias are only half the size. They are not exactly umbels, for the lower branchlets of the head run a few inches down the stalk and the large quantity of flowers comes up to the general outline on twice-branched stems. The individual bloom is curiously formed. First, there are two intensely green flattish bracts, spreading laterally, and about ¾in. from tip to tip. Between them the flower rises on a little inverted cone and spreads into a brown Maltese cross ¼in. in diameter. From the centre of this rise from one to three stamens with anthers bearing pollen, and from the same point droops the pistil. Fertilisation is further ensured by two other pollen-bearing florets which also hang by its side on shorter stalks. The leaves are of the long, narrow shape usual with euphorbias; they are of a curious dull leaden green colour, in sharp contrast with the brilliant metallic green of the flower bracts. The whole plant has the milky juice and the heavy, unpleasant smell common to the genus.—J. G.

Roses on a Dry Wall.

A DOUBLE dry wall was built to separate two garden regions. An old hedge bank stood near, but was in the way; as the wall was built up on both sides, the earth from the bank was barrowed into it, forming, when well rammed down, a solid mass 6ft. through at the bottom and 4ft. wide at the top. The joints of the wall were filled with suitable plants according to the two aspects, and the top was planted with a number of shrubby things. Among these are two of the older of the modern rambling roses, the yellow Aglaia and the pink Euphrosyne. They seem to delight in their place, flinging their flower-laden branches far and wide and only sending them down too low at the sides, where they have to be cut away to clear the footpaths.—M.

A Handsome Foliage Plant.

THERE is no doubt that, when well grown, cannas are more effective than the usual run of bedding plants. Owing to their extremely handsome foliage cannas may be freely associated with flowering subjects of all kinds, and their erect growth tends to counteract the flatness which is rather too obvious in many beds and borders. Another point of value in the canna is its power of withstanding the cold winds and storms of autumn. The dwarf-flowering hybrids are effective in beds either in conjunction with other plants or grown alone. They may also be dotted about herbaceous borders with great advantage. It must be remembered that cannas are gross feeders, and it is well to enrich the soil with well

Digitized by Google

decayed manure. To secure the best effect the position chosen should be sunny and somewhat sheltered. Cannas require plenty of moisture and are all the better for mulching. As required, provide the plants with stakes or they may be damaged during windy weather.—L. B.

Delphinium Belladonna.

AMONG the many fine delphiniums that have been raised of late, there is none, for purity of blue colour, that surpasses this old variety. It is a well defined plant in several ways, for it is the earliest to flower by a good fortnight; it is of very moderate height, and the bloom, instead of being closely set on the stem, has a certain loose quality that not only helps the colouring but has a distinct grace that is wanting in the spikes of more rigid pattern. Formerly it never set seed, but of late years it has formed seed freely. The resulting plants have much the habit of the original kind, but a certain mixture seems to have been effected, giving rise to a very useful class of plant that it is convenient to call "intermediate delphiniums." These are taller than the true Belladonna, and include some of much darker colouring, but nearly all retain the more open and less stiff form of bloom.—G.

The Purple Rock Violet.

Seed can be sown now in the open where the plants are to be grown.

THE plant known by some people as the purple violet cress is botanically known as Ionopsidium acaule. It is a delightful little annual plant, a native of Portugal, easily raised from seeds, and quite hardy in the warmer parts of this country. As a subject for sowing among spring-flowering bulbs in the rockery it is very useful, for seed sown in late spring flowers splendidly during the summer, and in many localities it seeds freely and resows itself, this second batch of plants flowering (providing the weather is mild) in December. As it is a surface-rooting plant, it does not rob the bulbs of their food, and it forms a pretty patch of colour where otherwise a bare space would be.

Ionopsidium acaule only grows about 2ins. in height, and when growing fairly closely together forms a carpet of tiny pale lavender-coloured blossoms. If the seed is sown in pans in the late autumn and carefully looked after and given the shelter of a cold frame, it flowers early in the year and is beautiful for the embellishment of the cold greenhouse or conservatory when little else is attractive.—T. H.

Canterbury Bells.

Sow this month and transplant in autumn.

THESE old-fashioned and well known hardy biennials should be sown about the middle of May if the best results are to be obtained. They may be sown in drills in the open ground, but a better plan is to sow in pans or boxes in a light compost and to stand them in a cold frame until germination takes place. A piece of glass placed over the boxes will conserve moisture and they should be shaded from sunshine until they appear above ground.

As soon as the seedlings show the covering glass and shading material must be removed and the boxes must be kept close to the glass and plenty of ventilation kept on the frame to prevent them from becoming drawn.

Prick off as soon as they are large enough to handle into nursery lines in the open ground at a distance of 6ins. apart, allowing 1ft. between the rows. Hoe frequently during the summer to promote free growth and keep down weeds. In early October they should be fine sturdy plants ready for transplanting to their flowering quarters. The best effect is obtained when the various colours are kept separate, and in the border three or five plants may be planted to form a group. A stake must be placed to each plant in early April, to which the leading stem must be tied at intervals. Liberal applications of dilute manure and soot water are beneficial previous to the flowering period.

If plants are lifted in autumn, potted into 6in. or 7in. pots and wintered in a cold frame, they make excellent subjects for the embellishment of the cold greenhouse in early summer. Care must be taken to remove any decaying leaves during the winter, and when water is applied it must not be poured into the centres of the plants. From March onwards frequent application of dilute stimulants should be given.

DELPHINIUM BELLADONNA, AN EARLY-FLOWERING VARIETY OF CLEAR SKY-BLUE COLOURING.

The cup and saucer varieties of Canterbury bells are, in my opinion, the most decorative of the several types on the market.—T. H. EVERITT.

Preparing and Planting Edgings.

IN the town, villa and suburban garden, formal bedding out is still in great favour, mainly because there is not much space for informal designs. In such cases, where the body of the bed is filled with, we will say, tuberous begonias of various colours, a distinct edging plant is essential. Of course, all such plants for this purpose, whether fine of foliage or flowering, must be dwarf and compact-growing. Violas are in the first rank for the purpose; the plants are compact, bear flowers freely and do not suggest formality in themselves. They may be planted now and all flower buds should be removed for several weeks. Armeria, too, may be planted now, also saxifragas, sedums, golden thyme, Euonymus radicans, dwarf campanulas and Cerastium tomentosum. Very little preparation is needed, but in the case of tender plants such as lobelia, pyrethrum, iresine, coleus, ageratum, Tagetes pumila and similar kinds, they must be gradually hardened to outside weather conditions by practically full exposure during the daytime in cold frames and by tilting the lights at night. By June 10th in the south and June 20th in the north the tenderest plants should be in a fit condition to plant out.—G. G.

The Panther Lily.

An Excellent Bulbous Plant for the Amateur.

THE panther, or leopard lily, of California is known as Lilium pardalinum, and there are several well defined varieties of this superb garden lily. It is one of the best in a beautiful genus, and, moreover, it is reliable, and will accommodate itself to most gardens. The type, L. pardalinum will attain a height of 5ft. or 6ft. and in July will produce heads of bright orange flowers copiously marked with purple-brown. A very fine form is californicum, with deep orange flowers marked with maroon the tips of the petals being an intense scarlet. This lily belongs to the Martagon set, the leaves are arranged in whorls, and the flowers more or less reflexed. When well grown I have counted as many as thirty flowers on a stem, and twenty is by no means uncommon. Even if a stem only produced half this quantity of bloom, it would still rank as a highly ornamental subject which has proved amenable to ordinary cultivation. Given dormant bulbs, planting can take place at any time, but preferably such work should be done in September or the spring, arranging the bulbs fully 6ins. deep.

Although this lily will succeed in ordinary garden soil, the greatest stature is obtained when a mixture of loam, peat and leaf-mould is provided in equal parts, to which is added a liberal sprinkling of coarse sand. Excellent results are secured in rhododendron and similar borders, in such positions the roots are kept cool, while the flower heads will appear above the shrubs and present a striking picture during the summer.

It delights in moisture at the root, but it must never be treated as a bog lily, and it will also thrive when naturalised in woods, such as an open glade or where the sun can reach it. In dense shade it is never a success, the growth is weak and the flowers pale in colour.—T. W. B.

CHRYSANTHEMUMS: PLANTING OUT FOR LIFTING

THE practice among amateurs of planting out mid-season flowering chrysanthemums for the summer, instead of potting them in their final pots in June, is becoming common in many quarters, and in this particular they are but following the custom of trade growers. There is much to be said in its favour, as where blooms are mainly wanted for home decoration and for cutting it answers well enough, provided that a little extra care is given them in getting the plants quartered, and again at the time of lifting in the autumn.

So many amateurs nowadays make use of their greenhouses during summer for tomatoes, growing them either in pots or boxes, or, as is sometimes the case, in beds within the house, that it is not a very difficult matter, in uprooting the old tomato plants, to use the receptacles or the bed which they have occupied, for chrysanthemum plants. It is a much more economical proposition than having to procure large pots specially for them, and, as I have said, where blossoms for the home is the object, it is quite satisfactory.

At the time of writing this note I have a number of plants in frames, and in the house, that, about the middle of May, will be quite ready for their summer quarters. This will be a large bed, in a place that is open to sun and air. I propose to augment the soil with remnants of potting soil, assisted with a little fertiliser. The plants will be stopped once before they are transferred to the open, quantity rather than quality of flowers being my aim. As on previous occasions, they will be planted out about 2ft. apart, a stout stake (not a cane) being inserted at the time of turning them out of pots, and during the course of the season one, or maybe two, other stakes will be inserted to prevent their being broken by rough winds, the shoots being tied to them as they grow.

Advantages of Planting Out.

A good many amateur gardeners have to be away at business most of the day, and only those who have grown chrysanthemums in pots can appreciate what labour is involved in watering plants night and morning in a time of drought. Planting out reduces this labour very considerably, although, of course, it does not entirely free the grower from going round them with the watering can at times. As a general rule, the one who adopts the planting-out plan is content to have flowers from terminal shoots, rather than attempt to take crown buds and aim at larger blossoms; but there is no reason why, if so desired, one should not select crown buds and have fewer and bigger blooms. My own plan is to have what I look upon as "serviceable" blossoms, *i.e.*, of moderate size, in larger quantities that give no qualms of conscience in cutting for home decoration, and I think many amateurs share these views to-day. The superb blooms secured mostly from crown buds demonstrate the skill of the grower; but most of us, I venture to say, are alive to the fact that moderate-sized flowers are mostly appreciated for table and home adornment.

Stimulants.

It does not follow, because one chooses to plant out instead of potting, that he should not help the plants; on the contrary, it will be found an advantage to give them help with stimulants from about July and onwards. Liquid manure, soot water, and a dressing of bone-meal occasionally, I have found give excellent results, if administered after rain or when plants have been watered. In making provision for planting out, one should be careful to leave an alley or path, and this will be found useful for getting between them. My own plan is to plant three or four rows, and then provide a space wide enough to walk up.

Lifting the Plants.

Early in September it will be necessary to consider arrangements for transference of chrysanthemums under glass. Should the weather be dry, plants should have a good watering, and the following day they should be "eased," *i.e.*, a spade thrust in the ground away from the plants. This may have the effect of their flagging for a day or two, but they quickly recover, and can then be got up and placed under glass in pots or boxes, whichever may be available, or holes dug out on the floor of the house, afterwards being inserted and soil applied as need be. Here, again, flagging may take place for a few days, but the amateur who has not tried the plan may take consolation from the fact that no plant more quickly recovers after removal than chrysanthemums. It will be needful to afford them abundance of air, night and day, for a time, and possibly have resort to shading should the weather be unusually warm. Taken all round, the plan of growing a number of plants in the open ground to provide flowers for cutting has many advantages for those amateurs who cannot, for various reasons, always give chrysanthemums the unremitting attention they need when cultivated in pots. W. LINDERS LEA.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

AT last the weather has taken a turn for the better and activity prevails in gardens and allotments throughout the land. But while winter conditions have given place to genial sunshine in daytime, there is a nip in the air when the shadows fall, and as the night temperatures drop to freezing point or under, there is still need for caution in transferring young plants from the shelter of a frame to bed and borders. So long as the wind remains in the east or north there is danger of early morning frost, necessitating the adoption of protective measures. The need for avoiding risks at this season is emphasised by the experience of a Mosspark reader of THE GARDEN, who lost all his calceolarias one night in early May as the result of the frame lights having been removed for the purpose of hardening off the plants.

Some gardeners have a very hazy idea of the manner in which bulbs should be treated when they have finished flowering and as the outdoor bloom of daffodils and tulips is nearing a close a few seasonal hints may be helpful. If the future usefulness of bulbs is to be considered, the foliage should not be removed until it shows signs of withering. Daffodils established in grass give a lawn or green an untidy appearance during the process of decay, but this may be accelerated by twisting the leaves of each clump into a loose knot. When it is necessary to lift the bulbs, remove the yellow foliage and spread them out in a single layer on a tray or shallow box until they have become quite dry, when they may be cleaned by taking off the dead roots and separating the large offsets from the parent bulbs. Store in a cool, airy place out of the reach of damp. Tulips are similarly treated. In the case of cottage and Darwin varieties, which are planted deeply in light soil, I leave them undisturbed for a few years and utilise the ground by growing annuals or other shallow-rooting plants overhead, but the early species are better to be lifted annually, especially when cultivated in heavy ground. Tulip and other bulbs forced in heat are of little further use and may be consigned to the rubbish heap, but treatment similar to that recommended for outdoor plants should be applied to bulbs from indoors in pots or bowls of fibre, which may be utilised for bed or border culture in the following season. Hyacinths are usually taken up every year and, according to the advice given by the late Rev. Joseph Jacob, they should be laid on a bed under a 2in. covering of soil, for a couple of weeks before being stored indoors.

Given suitable soil and weather conditions summer bedding operations in Scotland are general about the last week of May, when chrysanthemums, antirrhinums, nasturtiums, salpiglossis, tagetes, lupins, larkspurs and half hardy annuals may be safely moved to their flowering quarters, but owing to the high rate of mortality sometimes experienced with asters when they are prematurely transferred to the open, a few additional days devoted to hardening off is all to their benefit. The first week in June is quite time enough for planting out dahlias. Plants raised from cuttings and potted on are usually well advanced by that period and as a rule the change can be effected with little or no check to development. Collarette, cactus and other tall-growing types should be staked at the time of planting.

With the rapid increase in the popularity of the dwarf bedding dahlia Coltness Gem, it has frequently been predicted that the day of the scarlet geranium as a bedding subject was past. The merits of the little dahlia, its rich colour, free-flowering and good habit are beyond dispute and each succeeding year nurserymen in Scotland report an augmented demand, but the prophecy regarding the fate of Jacoby and Paul Crampel remains unfulfilled, for the old favourite geranium retains a firm hold on the affections of flower lovers. It still finds a place in public parks and private gardens and the much despised colour combination of blue, yellow and red provided by blue violas or lobelia, calceolaria and geranium still appeals to simple tastes. Tenement dwellers value the geranium as a house plant and it is equally at home in a window box and the artistic fire-clay vase which adorns the frontages of mansion house and villa residence. Both plants are easily propagated by cuttings and their culture is of the simplest kind, but the geranium is probably less affected by the absence of moisture in warm summer weather than any other flowering plant in the garden, and although it is dearer to buy, sales are on a larger scale than ever and several of our leading raisers anticipate a repetition of last year's experience, when stocks were exhausted before the close of the season.

Here are a few suggestions for growers of stocks. Try a bed of lavender and old rose colours in alternate rows, with a space of 12ins. between each plant. The effect is charming. White varieties and those of deep purple or rich carmine colouring also make an effective combination, particularly if they are used on a fairly large scale.

GROW ANNUALS FOR CUTTING

They are Worth Much and Cost Little.

ANNUALS possess in a superlative degree those qualities which are acknowledged to be indispensable to the decoration of the garden in summer, but their usefulness as cut flowers is not appreciated by amateurs to the extent that their merits deserve. Few subjects can equal them for producing a wealth of bloom at so small a cost and their culture is so simple that the novice may achieve success by the observance of a few elementary rules.

As grown in many gardens, however, annuals come far short of the ideal, simply because they are denied the space that is necessary to their natural development. The process known as thinning out is not properly understood and the plants are overcrowded in consequence. The first attempt at thinning is seldom adequate and such a thing as repeating this commonplace operation is the exception rather than the rule. The result is a thick mass of thin, weakly plants, inferior blooms and a comparatively short flowering season.

Herein lies a fruitful field for unnecessary work; but a practical example of the proper method of growing annuals from seed in the open ground would be more valuable from an educational point of view than all the teachings of theorists. Perhaps the day will come when civic authorities may see it to be their duty to establish model garden schemes in connection with public parks for the benefit of the public in general and particularly that section which inhabits our municipal housing schemes.

Annuals are divided into two groups, comprising (1) the half hardy type, which are raised under glass from seed and transplanted in the open, and (2) the hardy forms, which are generally sown in bed or border where they are to flower; and, naturally, their degree of usefulness as cut flowers varies considerably, as those dwarfer kinds that attain a height of less than 12ins. do not lend themselves to an artistic vase display to the same extent as flowers possessing longer stems. For instance, nasturtiums are more at home in the garden than indoors, and, on the other hand, there are a few tall examples, of which the Shirley poppies are typical, which have but a transient existence in a cut state.

The first class includes several favourite bedding subjects, such as asters, cosmea, chrysanthemum, sweet scabious (a biennial usually grown as an annual), and salpiglossis, but it is in the second group that the best varieties for cutting are to be found.

In the front rank the godetias deserve a place as their graceful sprays make a handsome vase. Several new double varieties have been introduced recently and the colour range comprises various shades of pink, mauve, lavender, crimson, etc. To appreciate the capabilities of godetia, allow from 9ins. to 12ins. between each plant.

The modern eschscholtzia or Californian poppy also claims distinction as a cut flower and the coreopsis are highly prized for cutting. Thin out the first named to 9ins.

Cornflower (centaurea) and Nigella (Love-in-a-Mist) variety Miss Jekyll are blue annuals that are qualified for both garden and indoor decoration, while the sweet sultans, which are of the same race as the cornflower, have come rapidly into favour on account of their pretty colourings and the fact that they retain their freshness in water for a long period.

An outstanding vase in the class for annuals at the Glasgow Gardens Competition last autumn was composed of Sutton's Lavatera Loveliness, and the single and double jacobæas, produced in branching sprays, were also prominent. The double forms are first rate for cutting as they are pretty and long lasting.

Gypsophila elegans grandiflora, with its feathery sprays of pure white flowers, is indispensable for indoor decoration. Where ever space permits, a small bed should be devoted to the hardy sea lavenders or annual statice, which in their dried state are available for winter use at a time when flowers are none too plentiful.

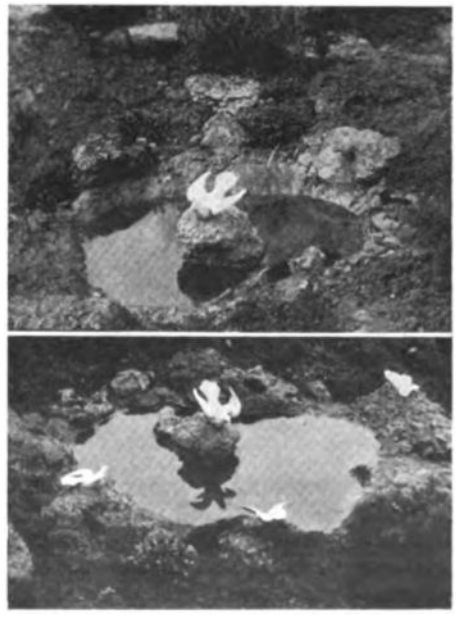
WHAT OUR READERS SAY

NOTES FROM A LITTLE SOMERSET GARDEN.

SIR,—One of the things to be noted in the little garden this spring has been the profuse blooming of the kerrias, single and double, and I have been once more struck with the greater beauty of the former. A specimen grown against a stone wall at the back of a narrow border facing east has been covered with myriads of the bright golden starry flowers that contrast pleasantly with the delicate green of the foliage. In front of the single kerria is a patch of Fritillaria Meleagris, the quaintly patterned "checker-lily" of the old gardeners, but this does not increase, I am sorry to say. A little farther along the same border, backed by clumps of doronicum and a white double cherry (Prunus japonica fl. pl.), Milla (otherwise Brodiæa, otherwise Triteleia) uniflora, has produced an unusual quantity of its dainty flowers. The type has white blossoms, faintly tinged with lavender-blue, but its variety M. u. violacea, which is grown together with it here, is pale lavender with a definite stripe of a darker shade down the centre of each petal. Both the millas are good for cutting and look particularly pretty arranged with double mauve primroses in a shallow bowl, with tufts of mossy saxifrage as a setting. But it is sad that so refined a flower should smell so pungently of garlic!

Anemone apennina flourishes and its drifts of soft blue have been beautiful this spring. It makes an ideal carpeting for the rose pink dwarf almond, Prunus (Amygdalus) nana, which grows barely 3ft. high, although Muscari Heavenly Blue, or Myosotis Royal Blue are nearly as effective, used for the same purpose. On the little rockery Oxalis floribunda has come safely through the winter (under a glass shelter) and its rose coloured flowers make big patches of vivid colour. The only two heaths that can be grown in this lime-loaded soil, Erica carnea and E. mediterranea, are flourishing (indeed the last named has outgrown its quarters on the rockery), but the colour of E. carnea was spoilt by frost. Wallflowers on the whole do well here, especially Cheiranthus Allioni, which seeds itself everywhere, although the hybrid Pamela Purshouse (C. Allioni × C. alpinus) has not survived the winter. That pretty little wallflower, C. Harpur Crewe has been very gay; it makes a trim little bush about 18ins. high, which is closely covered with small spikes of close-set very double flowers, brilliant orange-yellow in colour and very fragrant. It is admirable in a bed with myosotis as a carpeting or it may be effectively combined with the orange vetch, Orobus aurantiacus, Alyssum saxatile and orange tulips to fill a "golden corner."

The beautiful little Primula Juliæ, planted last autumn, has settled down well and opened quantities of its rosy-red flowers. Anchusa myosotidiflora is one of the most beautiful blue flowers in the garden and has bloomed very freely this season. So has the deeper hued Omphalodes cappadocica, but the blossoms have been badly attacked by some undiscoverable pest.—R. E. H., *Bath.*



A ROCK GARDEN LILY POOL AND BIRD BATH.

IN A LANCASHIRE GARDEN.

SIR,—In your issue of June 19th, 1920, you had an article on my rock garden (contributed by M. High), entitled "A North Lancashire Rock Garden."

I now enclose you two photographs, taken recently in the same garden, thinking they may possibly be of interest.

The bottom illustration is that of a bird pool or bath which I constructed comparatively cheaply both in time and cost. The pool is in perfect keeping with the surrounding portions of the rock garden, the sides being the exact colour of the weathered limestone about it. The water is about 11in. in depth, there is a small overflow pipe to keep it to that depth in wet weather. The pool is now one of the most interesting parts of the garden, being very much used by the birds.

The top illustration is a pool for a water lily, constructed in the same way as the bird pool, but larger and deeper, the depth of the water being 12 ins.

Last May I planted a nymphæa, variety Frobelli, a lily suited to this size and depth of pool; it did remarkably well, bearing, during the summer, ten blooms; of course, the accompanying illustration only shows the pool when it was taken the plant had not come into growth. This pool (apart from its occupant), cost me about 2s. and a Saturday afternoon to construct.—SAML. THOMPSON, *Lancaster.*

FROST AND YOUNG GROWTH

MANY gardens, particularly in the Midlands, east and north, have suffered severely from hard frost during the last week of April. In some areas the damage has not been confined to shrubs, such as rhododendrons, which are usually sufferers when spring frosts cut flowers that are just bursting and young shoots and foliage that are at their softest; even such hardy favourites as deutzias and philadelphus have had their young growth cut back to the old wood. A few genera have apparently escaped, such as lilacs and viburnums. One would expect berberis to have withstood the cold biting winds, but in many cases the flowers have succumbed, although the foliage has escaped.

With these warnings in front of them, all gardeners who value their shrubs should make every effort to look after those which have suffered severely to the best of their ability. Feeding and conservation of moisture are of the greatest importance, for not only must they be done thoroughly in order to ensure that the plant is able to put forth a great effort to repair the damage, but gardeners must take care that in their zeal they do not feed with unsuitable material or water at injudicious times. As shrubs are forming new roots at the present time fresh farm or stable manure must on no account be used, otherwise the roots will be burnt.

A liberal mulch of well rotted farm manure will do wonders, and so will a mulch of leafmould in which has been mixed a little of one of the many complete fertilisers now on the market. On the evening after the application a little water can be applied, which will ensure that the feeding properties soak slowly into the soil in which are the roots. If it is found impossible to give a mulch, the soil around each shrub should be thoroughly hoed so as to aerate the soil and a tablespoonful or two of some complete fertiliser sprinkled on the top, preferably in showery weather.

It is important that the damaged shrubs should have no further check from a long spell of dry weather, so, in case of drought, water should be both conserved and applied. A mulch will help to keep the soil around the plant cool and moist, as will consistent hoeing, which has the added advantage of keeping down the weeds. Water should only be applied after the sun is off the plant, and it is as well to remember that an abundance of water once a week is much more beneficial than small applications every evening.

A warning must be given against the immediate removal of damaged shoots and foliage. Frost damage rarely shows to its full extent until some time after the actual frost. Also, shoots that droop and appear to be dead may not be entirely frosted and so their removal might take away potential plant growth. Sap is flowing strongly at the moment, and consistent pruning down to green wood will mean much bleeding and consequent sapping of the vitality of the plant. It is unpleasant to see the tattered remnants of damaged young growth hanging on a shrub, but I should not advise its removal until the end of June, at the earliest, when shoots that are obviously dead can be nipped off, but even then green wood should be left severely alone. E. C.

OUR PHOTOGRAPHIC COMPETITION

In view of the number of excellent photographs which have been received from readers, many of which are as meritorious from the gardening as from the photographic standpoint, it is impossible to publish as many as we should like. Indeed, it is with no small difficulty that we select those to which awards shall be made. Numbers deserve publication for more than one reason. We propose to retain, unless the senders signify their wishes to the contrary, a selection of the more attractive photographs and to publish them from time to time, independently of the weekly competition announcement, when awards will be made under exactly the same conditions as if the photographs were published in connection with the competition itself. In connection with the receipt and return of photographs we would direct readers' attention to Rules 6 and 7. We must again emphasise the importance of supplying full particulars with each photograph submitted. These are taken into consideration by the Editor in his decisions.

MADONNA LILIES ALONG THE PATH SIDE.

The Guinea Photograph, sent by MR. CLARENCE PONTING, *Pangbourne.*

The old Lilium candidum is often said to thrive best in cottage gardens. Here it is seen in the garden of The Thatched Cottage, Pangbourne. The plants have remained undisturbed for several years, and are quite free from the lily disease. They make splendid spikes, 5ft. in height. Possibly this is due to the fact that the garden is an old one, and has a moist, loamy soil, ideal for the cultivation of this lily.

Digitized by Google

I enclose a photograph of a late summer border in my garden. This border, by judicious planting, provides a wealth of flower during many months of the year, from early spring on until late autumn. In the height of summer, delphiniums in all shades of blue and mauve, lupins and hollyhocks, phloxes and many other herbaceous plants are at their best, while from the end of August until October, the display is prolonged by means planting of many of the more modern varieties of Michaelmas daisies. Among those shown in the illustration are Ideal, Brightest and Best, Sam Banham and Ryecroft Pink. It is a splendid method to plant herbaceous plants so that a succession of bloom is obtained. Award of 5s. to MISS B. S. DAVIES, *Salisbury.*

A BORDER OF MICHAELMAS DAISIES.

An admirable way of covering a low wall is to allow sprays of rambler roses to drape over it. If the wall is of stone of neutral colouring, the effect is greatly enhanced. It is an idea which many amateurs might like to try to improve the appearance of their garden. Award of 5s. to MR. H. RUSSELL THOMSON, *Newnham-on-Severn, Glos.*

RAMBLER ROSES DRAPING AN OLD WALL.

I am sending you a photograph of a part of my town garden, which measures 14½yds. by 21yds. I am an amateur gardener and have myself planned, built and planted this little sunk garden only three years ago. Sedums, saxifrages and other rock plants are growing in the crevices of the low walls, and in the surrounding beds dwarf conifers, berberis, helianthemums, etc., are flourishing. Gentians are also doing well in this little garden. Award of 5s. to MR. JAC. KLEBER, *Amersfoort, Holland.*

In this portion of my garden I have made a semi-wild garden which, throughout the year, is most effective. Water lilies and various other aquatics are planted in the small pond, and at the water's edge small shrubs, such as the single white Japanese cherry and numerous foliage plants are grouped. These, as well as the cryptomeria close behind give very attractive reflections in the still water of the shallow pond. Award of 5s. to MR. H. L. P. BAKER, *Crewkerne, Somerset.*

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payments for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

When Building a Frame.

In construct ng the brickwork of a frame, the follow.ng will prove exceeding'y helpful : At about every three or four rows of br.cks, place two or more broken bricks opposite on both sides, project ng in towards the centre of the frame. The projecting bricks are of great value, because they act as supports for wooden shelves on which to rest boxes or pots of seeds, cutt ngs, etc. Therefore, if you have three or four of these rows, you can move boxes, etc., toward or away from the lights. The shelves should be about 9ins. w.de, 1–1½ ns. th.ck by the same length as the w.dth of the frame. With a small oil lamp placed in the centre of the frame it would make an ideal seed-raising compartment.—S. W.

To Kill Slugs.

Sink old jars or tins in the earth until their tops are level with the ground around them. Fill them wi.h salt and water right up to the brim, and sprinkle the top with a good layer of dry bran which will float, unless too much is used. The slugs, attracted by the bran, crawl on to it and sink. I have caught numbers in this way.—M. H.

Filling Gaps in Borders.

Very often in borders where large patches of bulbs have been planted for spring flowering a bare place is left for the summer when these die down. This difficulty may be overcome by sowing between the bulbs, while they are still growing, seeds of Shirley poppy, clarkia, marigold or any other dwarf-growing annual. The result will be a good display of bloom without injury to the bulbs.—W.

How to Make a Successful Marrow Bed.

Make a mound of any garden rubbish, cover with soil, then one or two barrow-loads of good short stable manure. Work up two barrow-loads of soil with a good sprinkling of slaked lime, shape it up, and leave it for a few days before putting in the seeds, taking care not to have it too sloping, or the water will run off when the plants are watered. A good way of protecting the young plants from frost or cold winds is to bend over some wire netting and cover with sacks or matting.—H. W.

For the Small Garden.

The small garden owner will find it of interest to set aside each year one bed and devote it to the growing of one special kind of flower, making a sort of speciality of it for that one year. The soil must, of course, be prepared accordingly. I have grown thus, in succession, carnations, antirrhinums, gladioli, dahlias and chrysanthemums. This brings variety into a garden where a great number of plants cannot be grown, preventing a monotonous sameness year after year. It increases the gardener's interest, enlarges his flower acquaintance, and informs him as to the special requirements of different plants. Flowers which are seen to do particularly well may, if so d sired, become a feature in the garden year by year.—J. L.

Gilia coronopifolia.

I have tried and failed more than once in the treatment of this plant as an annual, but grown as a bienn al it g ves g eat satisfact.on. I have planted out a fine batch of plants, about 100, and all over a foot h gh, that I expect to see from 2½ft. to 4½ft. in August. They were sown last May, grown on in 48's and 60's, with protection from frost dur ng winter. These plants were in the open and not injured by 12° of frost on Apr.l 2nd. I cons der them well worth the trouble of being on hand for twelve months.—A. H.

Red Spider.

Red spider very often becomes rampant on cucumbers, and it is not easy to use insecticides without risk of damagign the foliage. Heavy syringing and damping will not keep it in check. The best remedy is flowers of sulphur dusted on the foliage with one of the powder sprayers. This, if used when the first signs of an attack are seen, and at weekly intervals, will keep the plants clean throughout the season. The same plan of attack against this pest on peaches, nectarines and gooseberries has also been a success, and for pot plants it is quite safe and easy to apply, by holding the plant upside down and dusting the leaves by hand.—F. L.

Old Brooms.

When your old birch broom is too old for sweeping, do not use it for firewood. The handle will make a beautiful stake for your herbaceous border in summer, and the little twiggy bits are exactly right for supporting your sweet peas when only a few inches high and too small for the larger pea sticks. Ask your sweep to leave a little soot this year. Soot water is very good for pot ferns and aspidistras. Put some soot in a muslin bag and soak in water for a few days, and then water the plants once a week with it.—P. T.

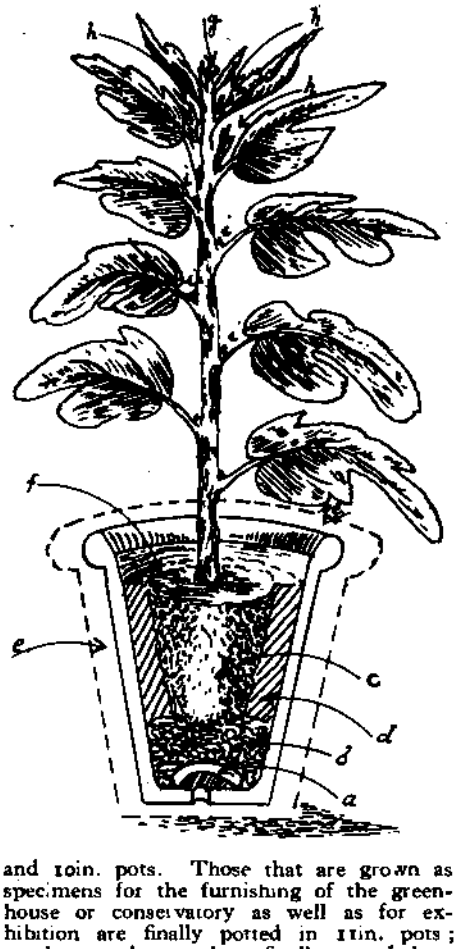
Michaelmas Daisies.

If growers of Michaelmas daisies in clumps will stop the front growths when about 9 ns. h gh, and those next beh nd at about 18 ns. h gh, leav ng the back g owths, they will obtain clumps flowering from base to top, instead of only on top.—F. S.

GREENHOUSE NOTES

Potting Chrysanthemums in Big Pots.

I AM referring to the final potting, the placing of the plants in the pots in which they are to flower. By big pots I mean those measuring 9ins., 10.ns. and 11ins. across. Plants grown to bear, say, three large blooms for exhibition are generally potted in 9in.



and 10in. pots. Those that are grown as specimens for the furnishing of the greenhouse or conservatory as well as for exhibition are finally potted in 11in. pots; so also are threes—those finally potted three plants in one pot. It is often found very convenient to place three plants in a single pot. Odd pots of this size may be so used when they would be quite unsuitable for single plants. It is a question of proportion, independent of any feeding that may be g.ven later on. As the plants are to remain in the soil until the autumn and even as late as Christmas, it is important that the compost used be of a simple m.xture and of a lasting character—that is, the bulk of it must be of fibrous loam. If it is of a heavy nature, add some sand and half-rotted leaf-soil. But I prefer builders' old mortar rubble—the dust and small lumps together. Instead of placing a large handful of broken crocks in each pot as a drainage material, place one large, hollow crock (as shown in the sketch) and a few small ones. Thus sound drainage will be prov.ded and, also, more room for potting compost and roots. A wedge-shaped potting-st.ck should be used, then the new soil can be well firmed without injury to the roots of the plants. In the accompany.ing sketch *a* snows the drainage; *b*, the coarser potting compost; *c*, the ball of soil and roots placed in position; *d*, the general new compost; *e*, the dotted lines denote the largest pot as used when three plants are grown in one; *f*, the space left at the top for watering and feeding. A bud, causing the first break, is shown at *g*; and the new resultant shoots at *h*, *h*, *h*, to be grown on. All side shoots below, at *i*, *i*, *i*, *i*, are to be removed. This in the case of plants being grown to bear exhibition blooms.—GEO. GARNER.

Clivia miniata.

THIS plant, also known as Imantophyllum miniata, is a very valuable subject for a greenhouse and it also thrives well in the window of a sunny room. In addition to having showy blossoms the clivia has very attractive leaves, wh.ch keep fresh and green in the somewhat unfavourable atmosphere of a living-room. Established plants in pots should flower each year with great freedom from spring on into the summer. The colour of the flowers is orange, each bloom having a buff-yellow centre. The blossoms, wh.ch are 3ins. across, appear in a cluster at the top of a th ck fleshy stalk, which is about 18.ns. h gh. There are a number of varieties wh ch differ to a greater or less extent from the type and some of these are d.stinctive and beautiful. Clivias are easy to grow, but it is not always that they flower so freely as

Digitized by Google

could be wished. This is usually due to failure to recognise that the plants require a period of comparative rest from October to January, during which period very little water should be given. During the spring and throughout the summer, the clivia revels in an abundance of moisture and applications of weak liquid fertiliser will be much appreciated. The common method of increasing clivias is by division or offsets, the best time being about midsummer, after the flowering of the plants. Clivias may also be raised from seed, but this is a slow method, as the plants do not reach flowering size until they are four or five years old. Frequent repotting is to be avoided, as the plants flower best when the bulbs have practically filled the pot. When a change is essential, the potting compost should consist largely of turfy loam, adding a little leaf-mould and crushed bones, as well as some coarse sand to make it porous. Arrange ample drainage in the bottom of the pots to provide a free passage for the abundant supply of water which will be given.

A Sweetly Scented Bulbous Plant.

THERE seems to be a general idea that the fragrant tuberose (Polyantha tuberosa) will not flower unless it can be given a somewhat high temperature. This is a great mistake, for, during the summer, tuberoses can be grown successfully in an ordinary greenhouse or even out of doors in a warm sunny position. It is very important that sound mature bulbs should be obtained, and before potting up remove all side eyes or embryo sprouts, as these will not produce blossoms and will only weaken the flower spike. A 4in. pot will accommodate a good-sized bulb, or three may be placed in a pot 6ins. in diameter. Make up a mixture of turfy loam 2 parts, decayed manure 1 part, and a few pieces of peat with enough coarse sand to keep the whole porous. The loam and peat should be used in pieces about the size of a pigeon's egg. The bulbs must be potted so that the neck of each is above the surface of the soil, making the latter moderately firm. Not much water will be needed until growth is active, applying it only often enough to keep the soil from getting dry. As growth advances, keep as near the glass as possible and give a watering with very weak liquid manure once a week. The flower stems will need the support of small stakes, as they are brittle and easily broken. In the open it is safe to plant tuberose bulbs after the middle of May. Choose a sunny, sheltered border, and let the soil be as light and sandy as possible. Allow the upper part of the bulbs to be just clear of the ground, but set the bulb as a whole firmly. In very dry weather water freely and be ready with stakes for the flower spikes. The natural flowering time of the tuberose in a cool greenhouse or out of doors is August. There is a fine double variety, called "The Pearl," much used by nurserymen and florists for decorative work.

Spring-Flowering Stocks.

Their Worth for the Cold Greenhouse.

ALTHOUGH in recent years much more attention has been paid to the culture of winter and spring-flowering stocks, it cannot be said that they are very popular with amateurs, possibly because most amateur gardeners regard the stock purely from one point of view, *viz.*, its culture out of doors, and so remain content with the Ten-Weeks. Unfortunately, so few understand that seed of the late and early blooming sorts, as represented by East Lothians, Beauty of Nice, All the Year Round and Christmas Pink, may be sown out of doors in June in light soil, pricked out when large enough and subsequently quartered in nursery beds, precisely as one does in the case of wallflowers, and then in the early autumn, pot them off very firmly into 6in. pots. I have bloomed them in 5in. pots on several occasions, but when this has been done, they were transferred into pots at the pricking off stage, and plunged in the ground for the summer. The larger sized pot, however, gives the best results as it gives one the opportunity of introducing a compost of old loam with a little old manure or bone meal. The stocks in question, if grown and bloomed out of doors should be found a sheltered place. They are almost as hardy as a wallflower, hence in a cold greenhouse one may bloom them quite well, a severe spell of frost, while hindering progress for a time, simply defers the spikes opening. Many amateurs associate their blooming, I think, with warm and genial conditions, but they grow sturdier and bloom better without heat. Plants can be left out of doors until October, as a general rule, and are best given a position in the house not too far removed from the glass, away from other tall-growing plants. Air should be admitted whenever possible. The spikes will be much improved if weak liquid manure is given the plants occasionally after housing them. One may have much colour in a house in spring by sowing seed of the sorts aforementioned, keeping a batch of plants in a frame until wanted in bloom, and so provide a succession. Even in a very hard winter plants so prepared will commence to bloom in the gentle warmth of a house, filling it with fragrance and beauty, but to apply heat is merely to hasten on, and is not absolutely essential.—W. F.

THE FRUIT AND KITCHEN GARDEN

Spinach for Succession.

IN very many gardens the supply of spinach is not equal to the demand and, sometimes, the little that is grown lacks quality. It is not always regarded in a serious light; not infrequently the inclusion of it in the garden is an after-thought, and it has to make shift with what ground happens to be spare. To grow spinach well it is scarcely possible to give it too much manure. The procuring of stable manure is still a problem with many, and if this is the case something should be substituted to provide humus. Wakeley's hop manure is very serviceable, and next to this use should be made of leaves, road scrapings and any old vegetable refuse which can be dug in, along with good dustings of soot along the rows. From now onwards sowings may be made every three weeks. Victoria is a well tried variety and is good for sowing at all seasons. In August space ought to be reserved for a sowing of prickly variety for winter.

I have found that if shallow trenches are made for the summer crop 4ins. or 5ins. deep, one gains an advantage should the weather become hot. Copious supplies of water and liquid manure afforded the plants in a dry time will prevent in a large measure their premature seeding. Seed is best sown in drills or, as suggested, a shallow trench. Space is sometimes available between rows of peas or dwarf beans, and use can be made of this for spinach. Thin sowing is recommended, otherwise thinning out will be necessary.—CLAREMONT.

Turnip Crops.

THE turnip crops are of great value practically throughout the year. Succulent roots only are appreciated, but it is often a difficult matter to obtain such during the hot days of summer. When judging at shows held during July, August and September, one finds roots staged that are dry and pithy in the centre; it is the exception, rather than the rule, to find sweet, firm-fleshed, juicy turnips. But such can be obtained by careful cultivation. From spring to mid August the sowings should be frequent, but small. Late in August and throughout September, the sowings should be on a much larger scale, as the resultant roots are grown in cooler weather and they are to meet the coming winter demand. Like radishes, turnips must be grown quickly to be satisfactory. It is useless to attempt to grow good turnips in a poor, shallow soil. Where such soils obtain and turnips must be grown on them, form beds 5ft. wide, throwing up the soil from the alleys to deepen the rooting medium. Add all the burned rubbish, rotted rubbish and any well decayed manure procurable and thoroughly mix all with the original soil. Dig and break up the latter deeply. Sow the seeds thinly, thin the resultant seedlings early. Hoe the soil between the rows at least once every week and do not water. Grow early maturing varieties and use the roots in a young state.—G. G.

Seasoning Herbs.

GOOD seasoning herbs cannot be grown in a shady corner of the garden, nor are they produced in perfection in cold damp summers.

Unless the plants are freely exposed to the sun during growth, the flavouring oils which constitute the essential properties of seasoning herbs are not formed in any great quantity, or in a high degree of perfection. The majority of these herbs owe their peculiar flavour to the presence of a volatile essential oil, which is stored up in small cells in the tissue of the leaves and stems. These oils are best preserved when the herbs are collected and dried without being crushed, cut or bruised, and without being exposed to the open air, and more especially to damp weather or rain. Some herbs, such as parsley, are best dried before a bright fire or in an oven and, when dried, put into air-tight bottles.

A warm, dry and sunny season is best for seasoning herbs, and the sunniest part of the garden should be selected for growing them.

Sticking Peas.

PEAS, generally, will need sticking now.

I recently passed an allotment where I saw a number of rows of peas sticked in a wrong way. I do not know whether they were tall-growing, medium or dwarf varieties, but the sticks used were very tall with branches at 3ft. to 6ft. from the base, the lower part being quite devoid of side branches. They would have answered the purpose if dwarfer, well branched sticks had been used also. But the tall ones should have been inserted in the soil at an angle of 60°, the angle being reversed on the other side of the row so that when one looked at the row from either side the spaces between the sticks would be diamond-shaped. I have referred to the rows on the allotment to illustrate the right and the wrong way of sticking peas. Neatness is, of course, desirable, but neat trimming should not be done at the expense of the pea haulm, which must be well supported. There is true economy, too, in placing the

Digitized by Google

sticks at the angle suggested, as fewer sticks will suffice to support the haulm. Also, it is important that the sticks be kept well apart at the top—quite 10ins.—otherwise the haulm will grow through both sides, fall over and leave the sticks bare of haulm at the top. Drive in the main sticks very firmly to withstand strong winds later on.—CHRISTCHURCH.

Sprays and Their Uses.

Bordeaux Mixture.

BORDEAUX mixture is a fungicide, and gets its name from the district of France round Bordeaux where it is largely used as a spray against the fungus diseases of the grape vine. Its chief use in this country, but by no means its only use, is as a preventive against potato blight. It can be used against a large number of diseases, and up to a few years ago was in fairly general use against the fungus diseases of the apple; but it is gradually being displaced by lime sulphur, owing to the injury its application may cause to the foliage and the fruit. Susceptible varieties of apples are Cox's Orange Pippin, Beauty of Bath, Lady Sudeley. The injury is shown by burnt patches on the leaves and by yellowing. The damage to the fruit takes the form of russeting and in bad cases may cause the fruit to crack.

The standard formula for Bordeaux mixture is: Copper sulphate, bluestone or blue vitriol, 4lb.; quicklime (lumps), 4lb.; water, 50 gallons.

To prepare, dissolve the copper sulphate in about one-fifth of the water by wrapping it in a piece of sacking and suspending it at the end of a pole just in contact with the surface of the water in a wooden tub and leaving overnight. The tub must be a wooden one. Place the quicklime in a wooden tub large enough to take the quantity of spray being made, and add the remaining water a little at a time, with constant stirring. Pour the dissolved copper sulphate into the milk of lime, stirring the while. Strain through a strainer and use immediately.

In spraying, it is essential to wet the surface of the leaves thoroughly on both sides, and the spray should be used in the form of a fine mist or fog by spraying through a fine nozzle under high pressure.

There is a number of proprietary brands of Bordeaux mixture on the market, and if one of these is used it is best to follow the directions given with the particular brand.

Pneumatic hand sprayers may be used if the quantity of spray material required is small. For larger quantities a knapsack sprayer is recommended. There are several good sprayers on the market, but remember to procure one with a fine nozzle with considerable force to produce a fine mist, and be sure to wet both sides of the leaf surface.

Bordeaux mixture owes its fungicidal properties to the presence of copper in solution. The copper is brought into solution either by the action of the carbon dioxide of the atmosphere on the mixture, or by the action of the fungus itself on the mixture. At present this is a matter of controversy.

The table below gives a list of diseases which may be controlled by the fungicide. The strength to use is given in the last column of the table.—H. B.

WHEN TO SPRAY WITH BORDEAUX MIXTURE.

Disease.	*When to Spray.*	*Strength.*
American Gooseberry Mildew.	Middle of January before the buds begin to swell ..	4—4—50
Apple Leaf Spot ..	(1) Spring, seven to ten days after petals fall. (2) Four weeks later. (3) A further four weeks later.	3—3—50
Apple and Pear Scab	(1) Just as the buds are beginning to separate in the flower bud.	4—4—50
	(2) Just as the petals have fallen	2—2—50
	(3) Ten to fourteen days later	2—2—50
Anthracnose of currants.	(1) When leaves unfolding. (2) Ten to twenty days later. (3) A further ten to twenty days later.	4—4—50
Asparagus Rust ..	(1) After cutting crop. (2) Ten days later. (3) A further ten days later.	4—4—50
Cherry Leaf Spot (on sour cherries).	(1) Soon after petals fall. (2) Two to three weeks later. (3) Just after fruit gathered.	2—2—50
Celery Leaf Spot ..	(1) On young seedlings. (2) Ten days later. (3) After transplanting. (4) Two weeks later.	4—4—50
Onion Mildew ..	On first appearance of disease and at intervals of ten days	2—2—50
Late Blight of Potatoes	About the middle-end of June or beginning of July, and three sprayings at intervals of ten to fourteen days.	4—4—50
Peach Leaf Curl ..	Previous to swelling of buds in spring	3—9—50
Tomato Leaf Rust ..	Spray the young plant once a fortnight until the fruit is beginning to set.	2—2—50

Concerning Late Carrots.

MANY amateurs imagine that carrots can only successfully be sown during March. This is quite a mistaken idea, as excellent roots may be obtained in many instances by inserting the seed right through the month of May, and even during the first fortnight of June. Such roots may not be so large as those obtained from seeds sown sooner, but as a rule the quality is there, and the flavour is often superb.

Successful Sowing.

For the benefit of those readers who have only recently taken up gardening, I would point out that carrots, whether sown early or late, require a soil which has been double dug, and which has been liberally manured for the previous crop. A mixture of equal parts of old soot and wood ashes may be forked a foot deep into the soil at as great a rate as a half-handful per square yard; but apart from this little is required.

The drills should be drawn so that they run due north and south. They should only be about ¼in. in depth, while each drill should preferably be 12–15ins. from the next.

Scatter the seed as thinly as possible along the drills, and cover very lightly with fine soil, this being preferably mixed with a little wood ashes.

Tips on Thinning Out.

Most amateurs attempt the thinning out on a dry day, but this again is a mistake. The rows can be much more quickly and easily thinned out if a wet day is chosen for the work, and a wet evening is about the ideal time.

Although it makes the operation a dirty one, it is very desirable, especially in the case of late-sown stock, to dust the plants with well aired soot immediately before and immediately after the thinning out has been completed.

Another useful tip is to earth the remaining carrots up slightly as soon as the rows have been thinned out, while a third idea is to dust the plants with sand, thoroughly wetted with paraffin oil, after thinning. All these tend to keep the carrot fly at bay.

While the small sorts only need finally to stand about 4ins. apart in the rows, the larger ones should have, at any rate, double or, better still, treble this distance allowed, if the best results are to be obtained.

Selections to Sow Now.

I recommend any or all of the following:

James' Scarlet Intermediate, which, although not new, is still one of the best.

Long Red Surrey, which it is claimed will produce longer roots than any other variety so far introduced; and

Carter's Red Elephant, of which I recently saw some specimens which were nearly 2½ft. from crown to tip.—E. T. E.

Sow Swedes in May.

SWEDES, or Swedish turnips, are now a recognised garden crop. They must never be sown too early, however, for frost has an inimical effect on seedlings and may ruin a crop; in excellent turnip-growing soil, I always sow during the second week in May. Seed may be sown a week earlier, if desired and further sowings may also be made until the second week in June. Ordinary garden soil serves for these, but preferably that which had a dressing of lime or slag last winter; a fair dressing of manure is also required and, in this connection, I may add that the farmer's plan is a good one, giving a good crop and economising in manure, *i.e.*, bury light manure dressings in drills, 21ins. to 24ins. apart, and sow seed over these, in due course. Seed is best sown when the soil is moist; in such a case it will germinate in two or three days, whereas in dry weather it may lie for weeks before it begins to grow. The man who grows a few drills only, should remember, too, that a daily dash of water from the syringe helps the seedlings considerably in droughts, preventing pests from gnawing the seedling leaves. In spite of general opinion, I am in favour of a good farm swede in preference to what are called garden swedes. The former grows bulbs averaging 6ins. in diameter, the flesh inside is of the choicest and the roots store well, if lifted in November and merely covered with soil. My choice would be St. Mungo, Best of All, Monarch, East Lothian or the Montrose, and seed is obtainable two shillings per pound, or less.—CLYDESDALE.

Lettuces in Dry Weather.

WHEN there are long spells of dry weather in the summer it is often an extremely difficult matter to grow good lettuces. It is really a very excellent plan to arrange that some of the lettuces, at any rate, are planted between the rows of root crops such as beet, turnip, parsnip, etc. The foliage of all these collect an unusual amount of dew and ensure a nightly watering of the ground where they are growing. This will be of great benefit to the lettuce plants, and often the hotter and drier the weather the greater will be the dewfall.

VOL. XCI.—No. 2895. MAY 28, 1927 PRICE TWOPENCE.

NOTES AND COMMENTS

Visit Wisley Gardens while at Chelsea.

WHILE on a visit to the Chelsea Show many gardeners express a desire to visit the gardens of the Royal Horticultural Society at Wisley. For the benefit of those who contemplate a visit we give the necessary particulars of how best to reach the gardens. The most convenient way of making the journey is to book from Waterloo Station to Kingston, and from thence travel by 'bus (No. 115) proceeding to Guildford. This service passes within five minutes' walk of the gardens on the Portsmouth Road.

Wisley, like most places, is suffering from the effects of the recent frosts, yet, notwithstanding the severe week at the end of April, many plants of interest are to be seen.

On the trial grounds the collection of Iris germanica, which consists of well over nine hundred kinds, is of special interest. Moreover, it is of considerable educational value to the gardener in providing a means for the comparison of the many types and varieties. Near by the iris will be seen a trial of over a hundred different stocks of aquilegia. These have suffered from the frost and continual bright sunshine.

The new alpine house contains many interesting plants in bloom. On the rock garden large drifts of phlox in various varieties are particularly bright. So also are the numerous varieties of helianthemums. Those who are keen on this free-flowering subject, which can be had in such a variety of colours, should not fail to see the trial bed of them.

Æthionema Warley Rose is a hybrid form of these beautiful plants from southern Europe, and is quite one of the best for grouping in large masses, being of neat dwarf habit with brilliant rosy pink flowers.

Bright patches of yellow are to be seen in masses of Alyssum gemonense, and orange of Cheiranthus Newark Park and Geum Borisii. In the wild garden are masses of Primula japonica. Azaleas have suffered extensively with frost and only a few of the late-flowering plants are showing colour. Rhododendrons of the hybrid class are contributing to the brightness of the garden.

In the new shrub garden, to which additions are being made annually, interesting shrubs of recent introduction are to be seen. This part contains a fine collection of heaths, cytisus and genista planted in the form of a heath garden. The herbaceous peonies are represented by a large collection, many varieties of which are in bloom.

Probably the most interesting feature at present is the various dry walls in front of the laboratory. These are clothed with plants of various kinds and are a wealth of bloom. A vigorous group of that beautiful plant Onosma taurica, the golden drop, is to be seen.

The display at the gardens, considering the season, is a good one, and all keen amateurs will find a visit of an afternoon to be well repaid. Apart from their beauty, they have much to teach even the keen gardener and much more so in the case of the beginner.

This Week's Work

For Gardens in the South and Midlands.

Harden off dahlias and bedding plants and begin to fill summer beds and window boxes.

Plant out border chrysanthemums.

Thin out shoots of asters, delphiniums and raspberries.

Sow turnips, peas, runner beans and lettuces.

Sow in the open seed of hardy perennials, such as lupins, delphiniums, campanulas, etc.

Lift daffodils and dry them off in reserve beds.

Plant out celery, cauliflowers and marrows. Earth up potatoes

Train and tie up climbers.

Sow cinerarias and Chinese primulas in the greenhouse.

Hints on Dry Weather Cultivation.

TO many garden enthusiasts, a spell of dry weather such as we have experienced during the past month or so proves very perplexing and frequently leads to the use of the hose pipe and watering can long before these are necessary, with the result that failure with various subjects is brought about which otherwise would have been avoided had they received more natural treatment in the way of surface cultivation. It has been stated many times before that regular stirring of the surface soil during prolonged spells of dry weather does far more to conserve the moisture in the ground and contributes more fully to correct root action than any application of moisture by artificial means. This applies especially to peas, beans in variety, potatoes, strawberries and other subjects in their class; and where it is found necessary to give an application to these, it must be carried out thoroughly, making certain that sufficient is given to get well down to the lower roots. In the case of salads, spinach, young carrots, turnips and other roots required for pulling in their young stage, watering may have to be resorted to at frequent intervals if their full flavour is to be enjoyed; and after one or two waterings the surface soil will get crusty and should be stirred between the rows frequently to admit air and warmth. Fruit trees and bushes, roses, herbaceous borders and shrubberies should all have the soil well stirred around them, and should it prove necessary for these to receive an application of water, a great saving of time and labour will be effected if this can be followed by a top-dressing of some approved material, such as rotten manure, lawn mowings or decayed leaf matter. If these are not available, continue stirring the surface soil, which will still have the effect of conserving the moisture down under for a considerable period.

Our Photographic Competition.

On page 352 of this week's issue will be found the photographs published in connection with our Photographic Competition. We urge all readers who are interested to send along photographs of their gardens during the summer months. The rules governing the Competition will be found on page xx.

This Week's Work

For Gardens in Scotland and the North.

Begin transplanting dahlias and other tender subjects.

Thin out hardy annuals sown in open border.

Make a first sowing of French beans.

Transplant cabbage for autumn use.

Mulch beds of exhibition onions with short manure.

Sow garden swede turnips.

Plant melons in frames.

Prick out seedlings of Brussels sprouts.

Fill window boxes and hanging baskets.

Take cuttings of arabis and aubrietia.

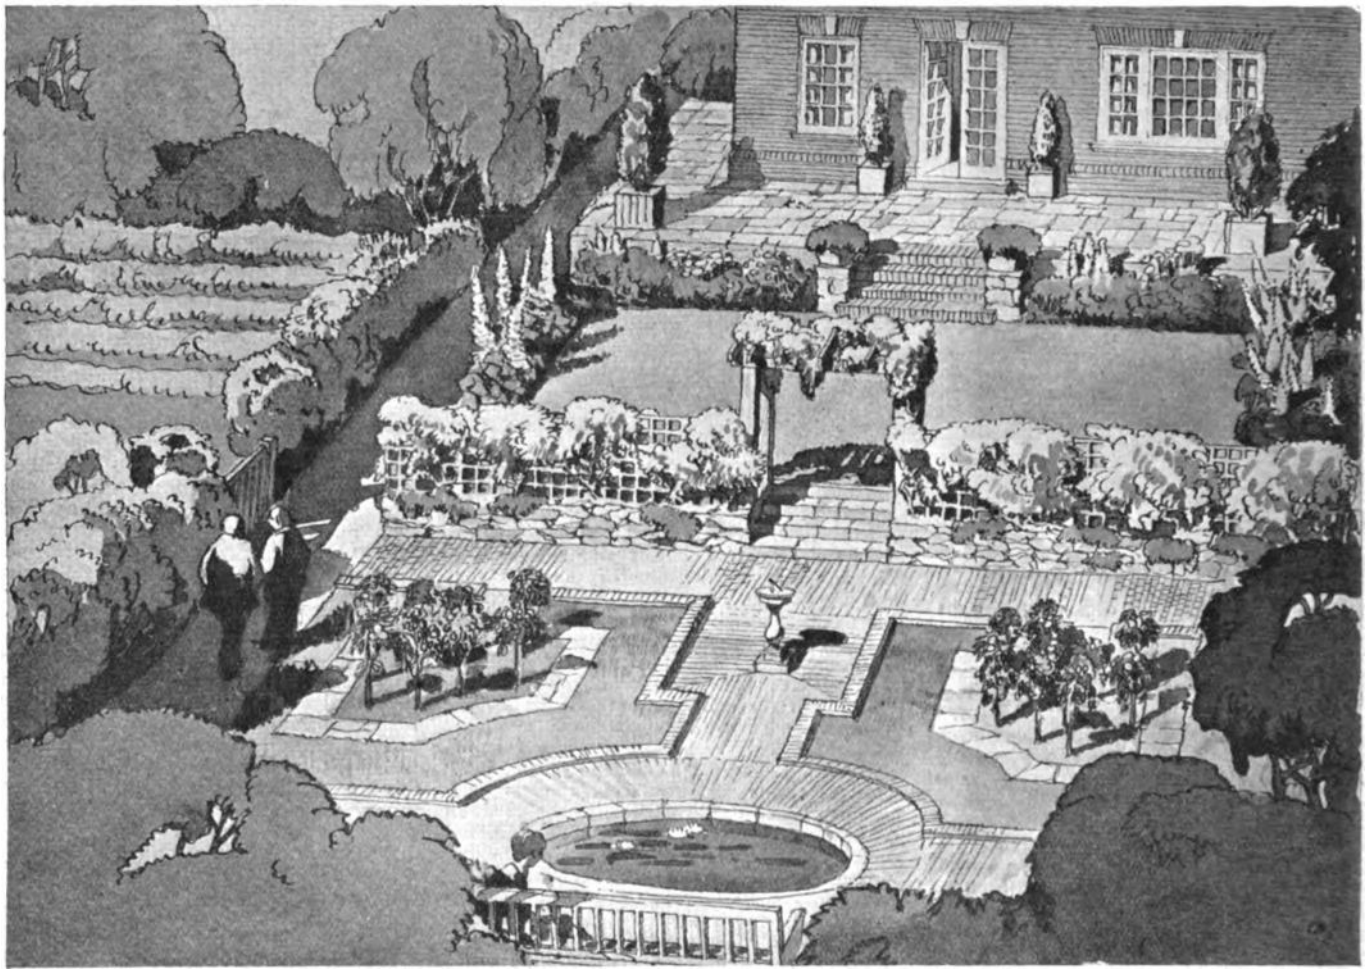
Complete lifting of bulbs from borders.

Keep sharp look-out for garden pests.

Digitized by Google

PLANNING THE SUBURBAN GARDEN

A simple scheme which embraces a lawn, flower beds and borders, rockwork and a lily pool. This terraced design is specially adapted for sites where the ground slopes away from the house. It is one which can quite well be carried out within the limits of a suburban plot.



Perspective by J. D. M. Harvey.

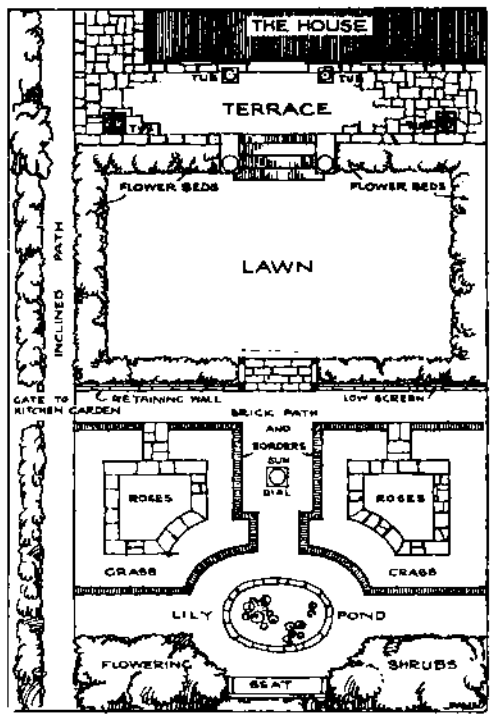
A CHARMING GARDEN MADE WITHIN THE LIMITS OF A SMALL PLOT.

THE accompanying illustrations show a garden scheme on a small plot which slopes gently downwards from the house. Such a plot involves more trouble than a flat site, but it also gives opportunity to make good use of differences in levels.

In the scheme now illustrated, there is a paved terrace next to the house. It is shown paved with rectangular stone slabs, but, if desired, brick paving (or even gravel) could be substituted. No flower beds are included in the paving, but shrubs in tubs placed on either side of the garden doorway and at the ends of the terrace are introduced to relieve any effect of bareness. In passing, it may be noted that the avoidance of flower beds next to the walls of a house has the merit of getting rid of any risk of covering up the damp-course and air bricks, thus conducing to the maintenance of a drier condition in the rooms.

From the centre of the terrace a flight of four wide steps leads down to a small lawn. these steps are bordered by a dwarf wall, and have little brick piers covered with slabs of stone, on which vases are placed. To the right and left of the steps is a border for flower planting, but, if preferred, a rockery bank could here be constructed, and would afford endless pleasure to the rock garden lover. The rockery would also serve as a revetment for the terrace.

On either side of the lawn are herbaceous borders, continued around to an arch which



is set over a second flight of four steps axially in line with the garden doorway, this arch is intended to be of oak, and joined to it on either side is a low trellis screen overgrown with roses. This screen is also intended to be of oak, with square trellis.

At the lower level now reached is an enclosure laid out with beds of standard roses set in the midst of plats of grass, and having a little paved walk, about 15ins. wide, around them. This gives a trim effect, and is also convenient for attending to the roses when the ground is wet. The grass plats are enclosed by bricks on edge, thus making a kerb, laid slightly higher than the main paths.

The centre pathway has a sundial set in the midst of it, as an item of interest. Then it opens out into an oval shape, surrounding a small lily pool, and the scheme is completed by a seat, again axially in line with the garden doorway, and having flowering shrubs planted on either side.

A lily pool is always a delightful acquisition in a garden. It can be constructed with concrete, and finished with a stone or concrete coping. It is imperative to make provision for the changing of the water freely, and facilities must be provided also for draining the pool. The latter is best effected by having a plug and chain similar to that in a bath. An overflow pipe must also be inserted, the water from both the overflow and the draining plug being conducted to a sump

Digitized by Google

or soak-away, which, obviously, will be at a lower level than the pool itself; it should be dug in some odd corner and filled with clinker or other porous material.

On the left-hand side of the plot a path extends, and half way along it is a gate leading to a kitchen garden (if space for this exists), but this kitchen garden forms no part of the scheme, the purpose of which is to show how a small sloping plot can be laid out with a lawn and a formal water garden. G. W. H.

GIANTS OF THE GARDEN

Among hardy plants there are few to compare in elegance with the giant asphodels or eremuri. A few of the species and garden hybrids are well worth growing where space permits. If attention is given to planting, which should be done early, and in affording protection to the young crowns from late frost and slugs, the plants will prove successful and a welcome addition to the summer display.

THE coming of the Chelsea Show recalls the magnificent display of these beautiful hardy plants. Last year a few of the early-flowering kinds were shown to distinct advantage by some of the exhibitors and attracted no little attention, since they are seldom seen in the average garden. There are quite a number of species, about thirty altogether, but very few of them are in cultivation, and if they were would make little or no appeal from the garden point of view, although it is possible that some of them might prove valuable for hybridising.

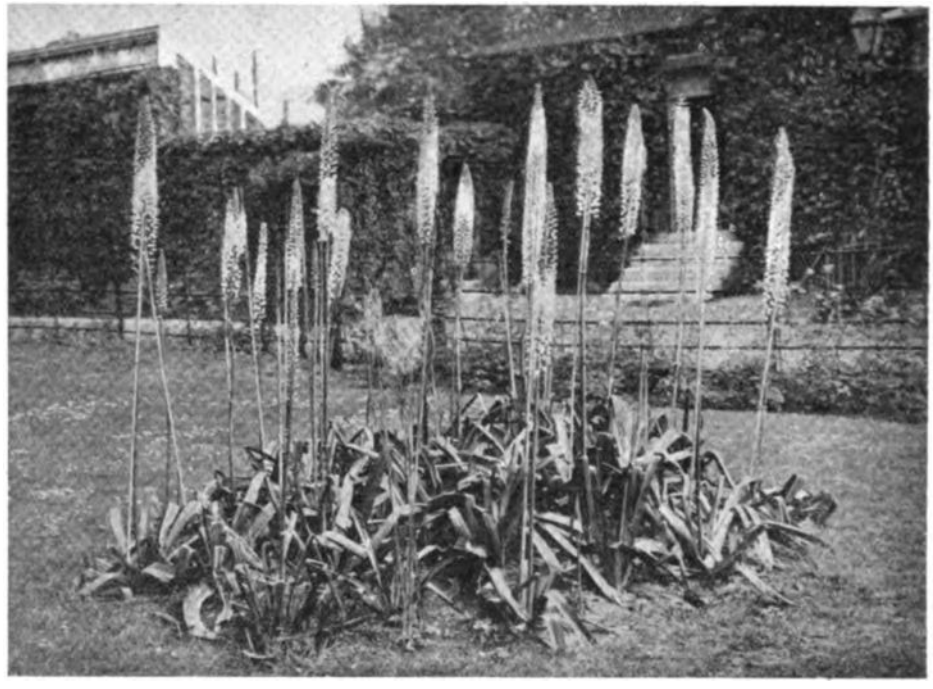
Eremuri come chiefly from Asia Minor, Persia, India, Turkestan and Afghanistan. They are very handsome plants, and strong-growing species, such as EE. himalaicus, robustus and the beautiful Elwesianus, when well grown attain a height of anything from 6ft; to 10ft., while EE. Bungei and Olgæ are smaller-growing sorts reaching a height of 3ft. to 5ft.

Planting.

Eremuri have quite distinct root system, the fleshy roots, which are very brittle, radiating from a central boss or crown like the spokes of a wheel. On account of the brittle roots, which are very easily damaged, great care must be exercised when planting or replanting them. Fortunately, it is not necessary to replant them often, provided they are well established in carefully prepared sites; although I may say there are exceptions to this, as to every rule, and the late H. J. Elwes lifted his collection every year and kept them out of the ground for several weeks, and he contended that that was the only way to grow them. It may be that in cold districts where they do not get properly ripened that there is something to be said for this method; there is, however, considerable risk of damage to the roots.

Choice of Situation.

Eremuri may be grown in the herbaceous border, but are really seen at their best when they can be grown in more or less natural conditions in warm, sheltered situations associated with groups of handsome foliage plants, being seen at their best against a dark background of shrubs or trees. They may with advantage be planted with moderate-growing shrubs, which afford them some degree of protection from frost and cold winds in their younger stages, for although they are perfectly hardy, they start to grow so early that they are apt to suffer from frost when they commence growing. At the same time the shrubs must be so thinly disposed that they do not shade the roots too much and thus prevent them getting properly ripened. They thrive in a rich medium loam, and as they dislike stagnant moisture, perfect drainage is very essential for success. The sites should be thoroughly prepared and should be trenched at least two spits in depth, working in plenty of well decayed manure, using cow manure for preference. If the existing staple is poor, a portion of the soil should be removed and replaced with good loam. On the other hand, heavy soil may have to be lightened by the addition of gritty material; in fact, a quantity of small stones is a distinct advantage, especially when dealing with heavy soils, for, as a rule, eremuri grow naturally in stony ground, thus soils that are close and pasty are very unsuitable for these plants. The time of planting is important, for there is no doubt it is unwise to keep them out of the ground for any length of time, although they may be kept out of the ground for possibly six or eight weeks without suffering any serious damage; indeed, as has been indicated, in the opinion of some cultivators it may, under certain circumstances, be an advantage to keep them out of the ground for several weeks. But, as a rule, it is certain that they may with advantage be left undisturbed for a number of years, hence the importance of preparing the sites thoroughly in the first instance. They should be moved after the foliage has died down, and planting may be done any time from the end of July to October, although, in my opinion, the best time is during August and September. Of course, where one has home-grown stock they may be replanted as soon as possible after they are lifted. In lifting and replanting great care must be taken not to injure the roots. The crowns should be covered with about 6ins. of soil, and if there is any suspicion that they may suffer from damp during the winter, some clean sharp sand should be placed underneath and over the crown of the plants. A surface dressing of well decayed manure should be lightly forked into the surface soil every year. Eremuri flower during the later half of May and beginning of June. That means that they start to grow very early, thus the young growth is apt to suffer from spring frosts, although when the foliage is more advanced it seems capable of withstanding a considerable amount of frost without injury. It is therefore wise to have some protecting material at hand in case of frost, Dry bracken or some evergreen branches will serve the purpose. An excellent method of protecting the young growth is to place large inverted flower-pots over them at night, removing the pots again in the morning. The advantage of this method is the fact that there is not any protecting material left around the plants during the day. They thus get the full benefit of light and air during the day.



EREMURI LOOK PARTICULARLY HANDSOME WHEN PLANTED IN A BED BY THEMSELVES, ALTHOUGH THEY ARE MORE COMMONLY GROWN IN A BORDER BACKED BY SHRUBS.

Species and Varieties of Garden Merit.

The species and varieties or hybrids commonly in cultivation are E. himalaicus, pure white; E. robustus, deep pink; E. Elwesianus, light pink; and E. E. albus. All the foregoing are strong growing and most suitable for general cultivation. Other species are E. Bungei, clear yellow, growing about 3ft. tall. This species has been used to a considerable extent for hybridising, Tubergeni being a hybrid between this species and himalaicus. There is also EE. Himrob, Shelfordi and Warei. E. Olgæ is also a good species. These handsome plants should be more generally cultivated, but many cultivators are deterred from attempting their cultivation by the mistaken idea that they are difficult. Provided certain essentials are observed, that is, a light, rich soil and perfect drainage, no one should experience any difficulty in growing them successfully. Given the right conditions, they are long-lived plants.

BLUE POPPIES FOR THE ROCKERY—II

A description of some of the best species for the amateur to try. Full cultural details were given in last week's issue.

THERE are many species of Meconopsis which are now in cultivation, but the following may be regarded as established favourites for the amateur to try:

Meconopsis Wallichii.—One of the earliest cultivated species, discovered by Hooker in Sikkim. Biennial. In the first year it forms a long carrot-like root crowned by a rosette of almost pinnate, sea green leaves, suffused with silken yellow hairs, giving a bronze colour to the whole. In the second year the tall central stem goes up like a rocket which, on bursting, shakes out a shower of sky blue star-clustered flowers, with a puff of golden stamens in the centre of each. There is a muddy purple flowered variety which should be shunned, though it is impossible to tell, even with seed saved from the bluest blood, whether it will go Bolshevik or not. To overcome this difficulty, some nurserymen pleasantly describe the flowers as varying from sky blue to "claret," as though it were a delightful and surprising discovery of theirs. Nurserymen who do that should be shunned also. It is, perhaps, hardly necessary to warn the bibulous against drinking "claret" of this particularly revolting hue! M. Wallichii in full bloom is a glorious sight, the 5ft. leafy stems being crowded with azure flowers which are borne in clusters all the way up. It requires a rich soil, and should be grown in half shade, or even in thin woods where clumps look particularly effective.

M. paniculata and *M. robusta.*—These are yellow-flowered biennials. The former resembles M. Wallichii in habit; the latter has the flowers solitary instead of in clusters. Both may be grown in clumps, in half shade, and, as with M. Wallichii, send up such noble spires of leaf and flower that a solitary plant on the rock garden, as aloof as a Chinese pagoda, always looks fine. They flower in May-June in the south, in June-July in colder parts of the country.

The familar prickly blue poppies include *M. Prattii*, a smaller plant than any of the above, not exceeding 2ft. in height. The pale blue flowers, which have a tendency to degenerate into washy purples, are borne singly all the way up the stem in an apparent raceme, though the topmost, of course, opens first. The whole plant is covered with short stiff prickles instead of with long silky hairs. M. Prattii, being less statuesque than M. Wallichii and its allies, lends itself to a more casual scatteration over the rock garden, and as it seeds itself freely, it is likely to do this anyhow.

M. PRATTII, WITH PRICKLY STEMS, FOLIAGE AND SEED PODS.

THE HAREBELL POPPY, MECONOPSIS QUINTUPLINERVIA.

M. latifolia.—This is closely related to the last, but is considerably taller, reaching 3–4ft. The flowers are of a dazzling azure blue, not so prone to wash out as those of M. Prattii, and deliciously scented. It is, indeed, one of the very finest species, requiring a light soil and full sun; it should be planted in clumps against a south wall, or at the foot of the rock garden.

It must, however, be borne in mind that all these species characterised by a central stem stuck all over with flowers have one blemish: the flowers—which, during inclement weather, last only a few days—open from above downwards, so that presently there is left a length of bare pole at the top, from the lower halyards of which flutter, like bunting, a few battered blooms. But, under favourable conditions, the poppyworts make such a fine display that a little peevishness of this sort may be forgiven.

I pass on to another group, comprising four species, two of which are in general cultivation.

M. simplicifolia.—The crown sends up, as it were, a *feu de joie* of rockets, each of which, descending again in a graceful curve, bursts into a large sky blue fragrant flower. Thus the habit is quite different from any of the other species described, for there is no main central stem, every flower (and there are usually two or three, or even four) having its own stem. The species enjoys half shade and may be grown high up on the rock garden for effect.

M. quintuplinervia, the harebell poppy, resembles the last in habit, but the flowers are smaller, narrow bell-shaped instead of saucer-shaped, violet instead of azure. It does remarkably well in some parts of Scotland. Colonies of this dainty species look particularly well in open pockets of the rock garden, and it has the advantage of being perennial. It can be raised from seed but is more readily propagated by division.

M. Baileyi is another sky blue perennial, though very different again from the last. A tall leafy stem rises from a great spreading crown of stalked leaves, bearing the half-dozen blooms each nodding at the end of a long pedicel, the three uppermost reaching approximately the same height (2–3ft.). The flowers are 4ins. across, with a shock of golden stamens. The stem leaves are unusually large so that flowers and leaves are lightly clouded up in a sunlit sea of blue, gold and green. M. Baileyi should be grown in clumps in full shade. It seeds readily, and may presently come from self-sown seed, or be propagated by division.

Lastly, there are:

M. integrifolia and *M. pseudointegrifolia.*—The former is the Tibetan Lampshade Poppy, and it has the largest flowers of any known species, sometimes reaching 6ins. across, otherwise it is a smallish plant, hardly exceeding a foot in height, and throwing up a fountain of chrome yellow balloon flowers from its short central stem. M. pseudointegrifolia is a taller plant with smaller flowers. Both are biennial, flowering in June. They may be grown in full sun or in half shade.

There is no space even to mention the two dozen other species which are or have been in cultivation under protest, as it were. Sooner or later—and generally sooner—these much petted prizes commit *hari-kari*, and, however eminently desirable they may be I cannot recommend them as possible garden plants while they are unprocurable. It may, however, be added that both the Welsh horned poppy and the curious little Californian annual poppy belong to this same distinguished genus, meconopsis.

F. KINGDON WARD.

A ROBUST SPECIES WITH YELLOW FLOWERS, M. PANICULATA.

THE CARE OF THE FLOWER BORDER

The value of early staking cannot be too strongly emphasised. It is a job which should be attended to at once before growth becomes too large. By early staking all danger of broken flower stems will be avoided.

IF a border is to show its best it must be cared for with unceasing watchfulness. Every few days there will be something that needs attention, for there are many small matters that, if not set right at once, will cause some defect that cannot be remedied later. Among the first plants that will claim attention are the clematises, that are so useful, planted in the back of the border to be trained over earlier-blooming plants that have gone out of flower; for even the Jackmanni section, that do not bloom till late summer, will want careful guiding from early June onward. Some of the low-growing plants will want early attention. Stachys lanata, one of the best carpeting things with silvery leaves, that is so valuable at a front edge in company with pink and purple flowers, will be proposing to throw up its ing spikes by this time. These upright growths must be cut down close, for the flower, which is on a stem 2ft. high, has no beauty, whereas the value of the plant is in the silvery foliage. As soon as it understands that it is not allowed to flower it spreads at the root and soon forms the perfect silvery carpet. Even earlier than this the spotted leaved Pulmonaria saccharata demands attention. This also has a flower that is of poor effect compared with the beauty of the leaves. The flowering shoots are well forward at the present time and should be cut out; a fortnight later more will have formed and must, in their turn, be removed, in order that all the strength may go to the handsome leaves. Heuchera Richardsoni, whose bronze red foliage is so good a foil to some of the warm-coloured early flowers should also have the flower stems removed.

A MIXED BORDER SHOWING CARE IN THE ARRANGEMENT AND STAKING OF THE PLANTS.

When the hardy plants are beginning to make strong growth, some of the first to want regulation will be the delphiniums. Well established plants make more shoots than are wanted. All the weakest should be taken out, leaving a small proportion only of the strongest, and these should at once have the support of some small branching spray. Clematis of the earlier kinds make early growth, and if not attended to in good time may become unmanageable. Branched spray such as is used for peas makes the best support, fixing it in any position that suits the intended disposition of the flowering masses. Others of the earlier border plants must be staked in good time. The fine deep yellow-flowered perennial mullein, Verbascum densiflorum, is one of these. It grows rapidly and, if not attended to in time, the heavy spike of bloom will be found lying down instead of displaying itself upright. Anchusa requires the same attention. Those useful border plants, the heleniums, especially H. pumilum and H. cupreum, though their height is under 2ft., should have the support of some short, stiff spray, or some day they will be found fallen down in a thick, sappy, unmanageable mass. By the third week of June Michaelmas daisies will have made good growth and will want some carefully arranged support. I use last year's pea sticks, striking them in between the plants; not using any ties, but leaving them so that, as time goes on, a little careful handling will guide the aster growths among the sticks in such a way as will show the natural attitude of the plants, while giving them just as much support as they need. Nothing is more deplorable than the fate of these beautiful things if staking has been neglected, till the plants fall down and are then gatheredup in shapeless bunches and tied to single sticks. Gypsophila paniculata wants some stiff spray thrust in firmly in such a way as to allow the young growths to come through and show the plant in its full beauty. Timely staking of the same class, but with taller stuff, is also wanted for that fine herbaceous clematis, C. recta, for the heads of bloom are too large and heavy to stand up without support. The tall Campanula lactiflora must be staked in time. This also has a heavy head of bloom; stiff spray or slender sticks must be carried up, cleverly concealed, to the very flower heads, or they will be broken down by wind or rain.

There is a great advantage in planting in long-shaped drifts rather than in blocks; it not only has a better appearance, but it makes it easier, when one kind of plant is out of flower, to train over, or to a certain extent bring forward what may be behind. G. J.

THE WRONG WAY TO STAKE AND TIE A PLANT
Note how ugly it looks compared with the next illustration.

THE RIGHT WAY TO TIE AND STAKE A PLANT
The plant has a more natural appearance, the shoots having room to develop properly.

LATE PLANTING OF ALPINES

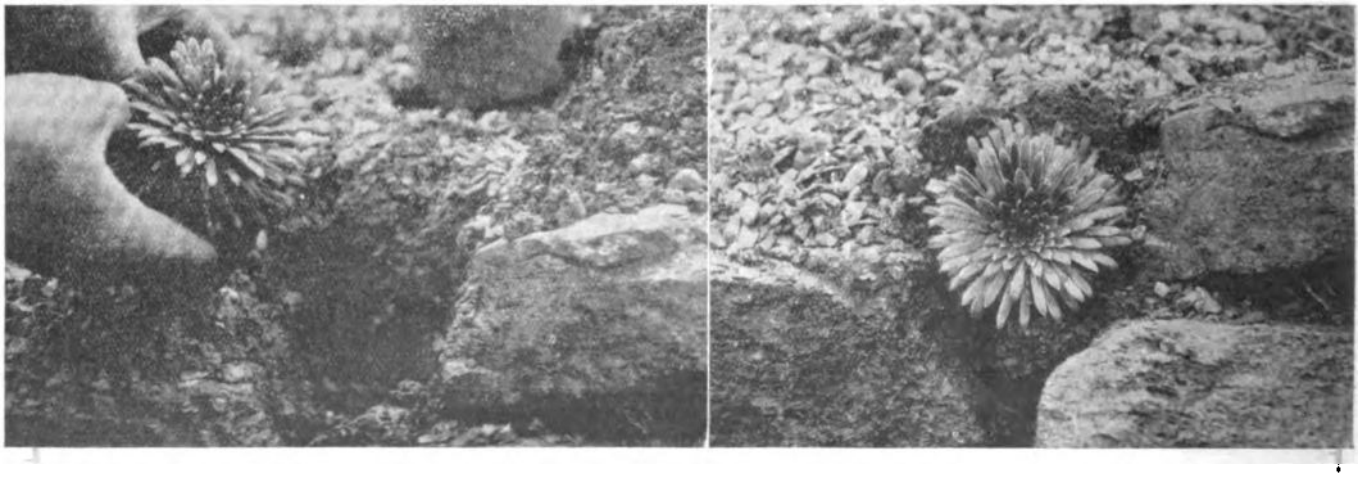
The idea that alpines can only be planted in spring and autumn is a mistaken one. Many alpines are grown in pots so that they can be safely transferred to the open ground even in the height of summer. If the plants are well watered they will soon become established. Summer planting is to be recommended for filling up gaps in the rockery.

ALTHOUGH the majority of alpines are best planted in autumn or early spring, it should be borne in mind that planting can be carried out even in the height of summer, if found necessary. The point to notice is to give the plant as little check in its growth as possible, otherwise small flowers and stunted plants will be the result. Prepare the soil pocket first by forking it up well and if the soil is in a very dry state, it is much the best plan to water the ground the day before. If it is given a good soaking so that the moisture penetrates well down, the soil should then be in a good condition for planting the following day. Be sure the plants to be planted are in a moist condition also by giving them a good watering the previous day. A moist plant turns out of the pots much more easily than when dry, the roots of a plant that is dry have a tendency to cling to the pot and will cause much disturbance to the root system, a thing that must be avoided at all times, more especially where late planting is being undertaken. Tap the plants out of their pots with care, so as not to damage foliage or any flower buds that may be showing. The crocks or other drainage may now be removed. This will free some of the roots, so that they will more readily take to the soil. No other disturbance of the plant is needed. Place the plant in the cavity prepared for it and press the soil firmly round the roots. Avoid pinching into the collar or neck of the plant a common fault with all beginners, and one which undoubtedly causes the death of many plants. The soil should be firm under a loose surface, which will get quite firm enough when the plants have been watered, and with rain. Watch the plants carefully for the next fortnight, seeing they do not get too dry, or eaten off by slugs and other pests that seem to have a special weakness for choice alpines. The plants should show marked improvement within a week and at the end of a fortnight the roots will have a good hold of the ground and will grow on quite happily with the same attention that is given to the established plants.

A few hints regarding the subjects that will move readily under this treatment may be useful to the reader. Shrubs will plant well if the roots are undisturbed, in fact I have a number of dwarf conifers doing very well on a dry wall that were planted in June without any ill effects whatever, and there is often a jutting point in the rock garden that can be improved by the dwarf Pinus sylvestris or Juniperus prostratus. Crevices too often get left till late in the season, and there is a wealth of subjects to choose from to fill these spaces, which will flourish if the roots get well down behind the rock; a plant that has all the soil knocked off by being squeezed into a narrow crevice and its roots mutilated, can hardly be expected to live. The saxifragas are fine crevice plants, especially the encrusted varieties, such as S. Cotyledon, S. longifolia and S. lingulata. S. longifolia is the pride of the rock garden, more for its beautiful silvery rosette than for its 2ft. to 3ft. long spike of white flowers. All these may be planted successfully even in full flower from pots. Campanulas, too, make a brave show and will thread their roots beneath and through any rockwork. C. Raineri and C. Allioni prefer this treatment, and the glorious open blue cups of C. mollis

PLANTING ALPINES FROM POTS.

The soil round the plant should be kept intact and a hole sufficiently deep to accommodate the roots taken out. After planting water the plants.



SAXIFRAGA LONGIFOLIA BEING PLANTED IN A CREVICE.

THE BRILLIANT SCARLET FLOWERS OF VERBENA CHAMÆDRIFOLIA.

PLATYCODON GRANDIFLORUM, WITH ITS HANDSOME BLOOMS.

are at their best when hanging from some high crevice, the woolly grey foliage making a fitting background to set off their elfin grace. These and many other plants will charm one from unexpected corners and niches, while other empty pockets may be planted late in the season with such plants as the prostrate Verbena chamædrifolia or Platycodon grandiflora, which bears large bell-shaped blooms of deep blue. Dianthus Lindsayi will do well and D. hybridus salmonius is at its best in late September. Erodium guttatum flowers all through the summer months if the seeds are picked off, as does E. chamædryoides, without this attention. Gentiana sino-ornata, with rich blue trumpets may be planted and will flower in September, following the upright cluster heads of G. septemfida. Pentstemon heterophyllus, with rosy blue and lilac flowers makes a brave show against the delicate frailty of Saponaria Wienmanniana's creamy rose flowers. Nierembergia rivularis makes a wonderful carpet of pinky white cups in late summer, as also does Œnothera macrocarpa's giant golden flowers on long flopping stems until frosts and rain call them to rest along with that flaming glory Zauschneria californica, whose scarlet flowers have at times cheered many November days. All these interesting subjects may be planted with a little care in May or even June, from pots and they should be a joy in the garden well into the autumn of the same year of planting. J. W.

NOTES ON THE FLOWER GARDEN

Ivy Geranium Mme. Crousse.

THOUGH there are a number of ivy geraniums of varied and deeper colouring, there is none that, for general garden use, surpasses this good old variety. Its clear pink colour and freedom of bloom are qualities that ensure it a welcome in every garden. The illustration shows it at the top edge of a low dry wall that retains a narrow border and a path next a house. The place is in rather poor soil and in full sunlight. It is not quite hardy in the home counties, but stands out in the Isle of Wight and the mild climate of our south-western counties. It is a capital plant in a cold greenhouse or any well lighted structure that is safe from frost. It is curious to notice that the leaf of ivy geraniums not only has the shape but also a smell that closely resembles that of ivy.—G. J.

ONE OF THE BEST OF IVY GERANIUMS, MME. CROUSSE.
It should be grown in every garden.

For the Sunny Rock Garden.

THE sternbergias are very interesting plants which are suitable for a warm south or a sunny part of the rock garden. Some of the species are of special value, owing to the fact that they blossom in the autumn and winter and produce large quantities of golden yellow flowers. Other species are spring-flowering, and these will usually follow on the crocuses. The soil for sternbergias must be well drained, light and sandy, while at planting time it will improve matters to mix in some leaf-mould round the bulbs. Those which are to flower in the autumn should be planted during June or July, and the spring-flowering kinds in September or October. The bulbs should be put 3ins. deep and from 4ins. to 5ins. apart. Increase of sternbergias is carried out by the division of offsets, which should be removed at the seasons recommended for planting. When the bulbs have settled down and have shown that they are happy, it is much better not to disturb them, as they will then go on growing for some while, providing they are not seriously overshadowed by other plants.

The chief autumn-flowering sternbergias are as follows: S. lutea, flowering from October onwards; S. macrantha, often in bloom up to the end of the year and S. colchiciflora. The best known spring-flowering sternbergia is S. Fischeriana, which open its golden yellow flowers in April. The sternbergias grow to a height of from 6ins. to a foot.

A Dainty Erigeron.

FOR a close-up ledge in the rock garden or stone trough, the soil being light and gritty, Erigeron rifidus will prove a most engaging little plant. It makes a neatly rounded tuft of rather deeply lobed, hairy foliage and from April onwards for a long period produces a succession of daisy flowers on 2in. stalks. These are large and bold for so small a plant and they are a beautiful pale lavender. This should also make a good moraine subject, but it seems to be soundly permanent in a poor, stony soil, which ensures

Digitized by Google

thorough drainage. Full exposure is desirable. E. trifidus appears to be synonymous with E. flabellifolius and is closely allied to the equally delightful E. compositus.—A. T. J.

A Creeping Sandwort.

ARENARIA BALEARICA is a plant of miniature growth, well adapted for sunless corners and cool positions on the rock garden, while it is also useful for crazy paving and low retaining walls. It is a good grower and, if afforded a congenial position, it increases rapidly, and will neatly clothe everything with its vivid green, soft felt-like growth. The damp, shady side of a rock covered with A. balearica is very attractive, especially when the countless numbers of small starry white flowers are in evidence from May till July. The creeping tendency of this plant is somewhat similar to a tiny moss, and it is scarcely half an inch in height. On account of its free seeding qualities, seedlings are frequently found in close proximity to the parent plant, and these, if not required, could be lifted and transferred to other suitable stations. Moreover, the old plants can be divided at any season, and if the position is kept damp for a few days it quickly becomes established. As this small sandwort has a decided preference for shade, it will be found useful in the garden where the rays of the sun are seldom present—B.

Artemisia lactiflora.

WHEN a new plant comes into our gardens it takes a season or two to make its close acquaintance and to see what are the best ways of using it. This 5ft. high artemisia proves to be one of the easiest things to grow, and its creamy spikes of bloom are a welcome addition to the flowers of late summer. There are some who have expressed disappointment, because at the moment of its fullest bloom it looks as if it might be going to do something more and does not do it. Yet anyone who is generally acquainted with the genus cannot but see that it already makes a showier head of bloom than any other that is commonly in cultivation, and when we are content to accept its natural limitations we are amply repaid by finding out how good it is to use, if not for its own merit alone, as a delightful companion to other flowers. We all know the unsatisfactory appearance of the lower parts of sunflowers—lanky yellowish legs—and, even if the only sunflower grown, as in the garden where this note is written, is the primrose-coloured tone of moderate height, yet its bare stems are equally unsightly. But if the sunflowers are inter-grouped with the artemisia, so that they look out above it and among it, the whole thing is unusually pleasant both in form and colour; and if, in the same grouping, there is, still farther back, some pale yellow hollyhocks and a Clematis Flammula trained over pea sticks, the whole thing becomes a charming picture of varied form and agreeably related colouring.—J.

THE FEATHERY CREAM COLOURED SPRAYS OF ARTEMISIA LACTIFLORA.
A fine shrub for late summer decoration.

Campanula pyramidalis.

A bellflower which every amateur should grow in his garden.

WHEN a garden is well established, many pleasant surprises come of themselves. Such a one is the successful flowering of a plant of the Chimney campanula that placed itself at the edge of some shallow steps that lead away from the house to some slightly higher ground. The self-sown seedling plant has been there three years; one year it sent up one spike, but it was wrecked—wrenched out at the bottom—by a storm of wind.

When the steps were built there was no intention of leaving spaces for growing things, and the ground below is almost pure sand, so that the plant must have had some difficulty first in penetrating the mortar joint and then in finding any kind of nutriment.—G. J.

Some Autumn Crocuses which Can be Planted Now.

They are suitable for the rockery or front of the border.

FEW garden effects can be more pleasing than colonies of our native meadow saffron, Colchicum autumnale, growing either in a border or naturalised in grass in a small corner of the garden. The foliage of these bulbs appears in spring, and immediately the ample leaves become yellow and wither off is the best time to procure and plant new bulbs or to transplant one's existing stock.

Colchicums, and more especially the large-flowered species, never look better than when naturalised in grass. The situation should be fairly open, as it is most essential that the bulbs should be well ripened preparatory to a new season's growth.

The smaller species and those of some rarity may be accommodated in the rock garden or in a border; as a matter of fact, all colchicums are very beautiful on the rock garden when in flower; but, alas! the very large leaves of such species as speciosum have a deleterious effect during spring and early summer and are extremely untidy from the time they commence to "yellow."

Disturbance is much resented by these bulbs, and, indeed, long-established colonies will provide one with mature and colourful beauty during late summer and early autumn.

Of our native C. autumnale there are several very pretty and distinct varietal forms, notably roseum (syn. Tenorei), album, album plenum, plenum double lilac, atropurpureum of deep and attractive colouring. The giant speciosum from the Caucasus rears up huge goblets of rosy carmine colouring, and a lovely variety of intense colour is Ruby Queen, ruby red with a white centre; the var. illyricum from Salonika has its soft rose flowers lit up with golden anthers, a choice and beautiful blossom.

THE ELEGANT CHIMNEY BELLFLOWER, C. PYRAMIDALIS.

C. speciosum album has been called the finest of all autumn-flowering bulbous plants, and it is most difficult to visualise anything more chaste or more lovely than the large purest white goblets, their beauty enhanced by that slight stain of greenish yellow at the base; a few open flowers never fail to bring forth exclamations of admiration and this plant should be in every garden where good plants are valued. An intermingling of this fine colchicum and Amaryllis Belladonna makes a charming association.

C. giganteum from Asia Minor is of large size, soft rose with a white centre, and somewhat reminiscent of this fine species is the well known C. Bornmuelleri with a larger expanse of basal white. Mixed varieties are excellent for naturalising and should be planted in bold drifts.

The species with chequered flowers are both quaint and pretty, the better known plant being C. variegatum, flowers chequered rose-purple and white; and C. Parkinsonii, white tessellated and barred purple and of rather starry form; these, with their congeners, will give much that is desirable to the garden in autumn, the wholly appropriate setting provided by the golden brown and crimson of the fading year, enhancing the beauty of the great crocus-like blooms.—R. E. A.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Seeds to Sow Now.

IT is much more fun to grow one's own plants from seed than to buy them ready for flowering. And it is much cheaper. A number of the brignt flowers which are now just putting off their gay attire are very aimple to raise from seed. Forget-me-nots, wallflowers, honesty, all of which have been specially find this spring, can now be sown. Use boxes or pans of rich soil, and prick out the seedlings as soon as the second pair of leaves have formed.

Stately Hollyhocks.

It is not generally known that hollyhocks are quite easily raised from seeds. Buy a good, strong plants to put out in their permanent quarters in autumn. Sow in the open or in a box, and transplant into a nursery bed. They like a moderately rich soil, and plenty of light and air to ensure sturdy growth.

Money-in-Both-Pockets.

This is another name for honesty (Lunaria biennis), given to it on account of the position of the seeds on both sides of the pod. The purple flowers are not unlike those of the wallflower in form and are followed by the "silver spectacles" so often seen as winter decorations. The plants are biennial, and like to grow in the shade, beneath orchard trees, etc. Common garden soil will do, and the seeds can be sown as advised for Canterbury bells.

AN ATTRACTIVE TOWN GARDEN WITH ITS SMALL BEDS FILLED WITH SUITABLE BEDDING PLANTS.

good strain, and grow them in rich soil. Red spider sometimes attacks the leaves, but this pest is easily controlled by spraying well with water. Double hollyhocks do not always come double from seed, but the richer the soil, the greater will be the percentage of doubles.

Sweet Williams and Columbines.

These two old-fashiomed flowers are hard o beat for beauty and sweetness. They flower in the lull between spring and summer flowers and are specially valuable where successional flowers are desired. Sow seeds in boxes and plant out 6ins. apart in the nursery bed. Only lightly cover the seed with soil—a good rule is to cover twice their own depth. When the seedlings are put out, it may be necessary to water if the weather is dry. Excellent new strains of these hardy flowers are obtainable from all the leading seedsmen.

Canterbury Bells.

These flowers, in various colours of pink, white and blue, are very showy biennials. That is, they make growth one year, and flower and die the next. The secret of their culture is to sow early enough to secure

Use and Beauty Combined.

HAVE you a bare and ugly wall, or a trellis, or archway which you would like covered with greenery during the summer? If so, there is no better plant for this purpose than the ordinary scarlet runner bean, for not only is it a popular vegetable, but its flowers and foliage greatly enrich the appearance of the garden.

On the allotment, runner beans make an excellent screen plant, and for this purpose should be on the north or east side of the plot. If the land has been dug and manured, the only further preparation needed is to draw a drill 3ins. deep where the row is intended. Place the beans in the bottom, 8ins. apart and cover with the loose soil. Stakes, string or other support need not be fixed until the seedlings are above the soil. Fairly tall supports are necessary, as in ordinary garden soil beans attain a height of 6ft. or 8ft. Should this height not be desired, the tops can be pinched out when the desired height is reached. Some growers pinch out the tops when the plants are a foot high, and, in this way keep the plants dwarf; but of course, the bean pods gathered from these are not clean. Two of the best varieties, which are both useful and ornamental, are Scarlet Emperor and Painted Lady. Both of these are strong growers.

The King of the Begonias.

VARIETIES of the Rex section of begonias are often cultivated as window or room plants. They are grown chiefly for their richly coloured foliage. For a shady border in a greenhouse or a cool fernery begonias are very useful plants. They are used to decorate walls, and in this case the wall is first covered with wire netting, supporting fibrous soil or sphagnum moss, and in this the begonias are planted at intervals. During growth they require copious supplies of water, but like the tuberous section, they are best kept dry during winter.

A Plea for Simplicity.

WITHOUT being too conventional, one can gain a good deal by adopting a simple scheme of bedding out, and *sticking to it*. A mixed border is a perpetual charm, and has in it always something at its best. But the geometrically shaped beds cut in lawns lend themselves to simple treatment in the matter of summer flowers. Two or three kinds chosen with an eye to colour and height, will give a better and more lasting show of bloom than a larger variety. The deep blue Salvia patens, for instance, contrasted with white alyssum, makes a strikingly beautiful subject for a small flower bed. Antirrhinums, of two colours and two sizes, with an edging of lobelia or tall fuchsias, with a carpet of dwarf begonias, are other suitable selections for this purpose. The small symmetrical flower bed is viewed as a whole, and should be planted with this in mind.

Treatment of Tender Vegetables.

MARROW seedlings are now showing their first pair of leaves. No time should be lost in preparing a site for them. The common belief that a raised mound of manure and soil is necessary for marrows is wrong. These plants will grow equally well on the flat, if the soil is deeply dug and manured. Bush marrows are best for small gardens, but if a piece of waste land is available, the trailing sorts make admirable "smother" plants. Water, in liberal quantities, must be given to marrows, especially during the first few weeks.

Celery trenches should be opened, and a good supply of manure forked into the bottom. Celery is a semi-aquatic plant and commercially grows best on marsh land. A moist part of the garden should, therefore, be chosen.

THE BUSY MAN'S PAGE

Chrysanthemums in Pots.

IT is very important at the present time to watch potted chrysanthemums closely to see that they do not suffer from dryness. It is a great mistake to allow the soil to become dusty, even for a few hours, as this seriously checks the plants. In warm, dry weather go over the plants twice a day, at least, testing the pots with the knuckles or a small mallet and if a sharp ring is the result, water will be needed. Then provide the chrysanthemums with liquid manure, which may be of almost any kind, providing it is weak. As a matter of fact, it is an excellent thing to change the character of the fertiliser, as plants benefit greatly from alterations in the character of the food which they absorb through their roots. Very weak solutions of fertiliser may be given several times a week with great advantage. As the chrysanthemums grow, provide them with stakes which will ensure a straight growth of stem and also prevent breakage by wind.

Bedding Calceolarias.

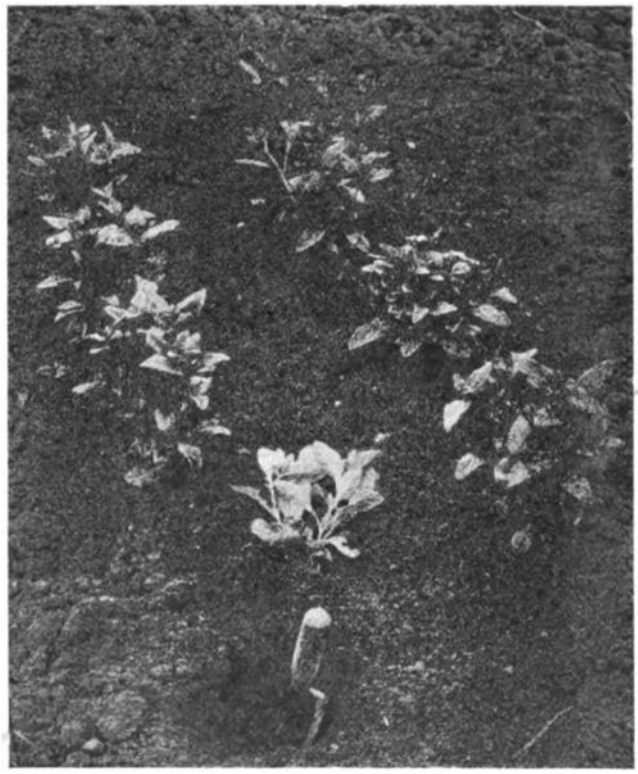
BEDDING calceolarias were at one time considered a most essential class of plants for the adornment of the garden in summer and there were few bedding schemes which did not include a goodly proportion of these, particularly of the yellow and brown shades. Nowadays they do not, however, figure quite so prominently, having either been displaced by the larger and more brilliantly flowered greenhouse varieties or by some different class of plants entirely, with the result that many of the once popular varieties are now difficult to procure.

Fortunately, for they are charming little plants, it is still possible to obtain these in sufficient variety to enable them to be used with good effect either in bedding schemes or to brighten up some portion of the garden.

Provided the weather is at all favourable, these may be planted out now, and, as short jointed stubby little specimens give much better results than long spindly ones, preference should be given to the former when selecting one's plants. Success or otherwise depends to a certain extent on the season, as a very hot, dry season considerably shortens their period of usefulness, but as coolness at the roots is appreciated by this class of plants, these should be planted in a fairly rich loam, which has been deeply cultivated. The space allowed between each plant depends on whether they are used as dots or massed, but well shaped symmetrical plants can only be obtained by permitting ample room for development and the ground between the plants should either be carpeted with a dwarf subject to keep the roots cool or else stirred regularly with the hoe for the same purpose. The well rooted plants shown in the accompanying illustration shows admirably the type of plant most likely to go ahead when planted out now.

Transplanting Half-Hardy Annuals

THESE annuals are raised under glass, in the greenhouse or frame, where a very early display of blossom is required. They are gradually hardened and then transplanted in prepared borders. When all detail work is well carried out the plants thrive splendidly, but most of them fail to give satisfaction when the work connected with the transplanting is badly done. They should be treated as follows: Take extra pains with soil of a cold, adhesive nature; thoroughly break up the lumps and reduce as many as possible to powder. Procure some finer loam—such as that from the potting bench or some heap where tree leaves and other material of a similar nature have been laid to decay. Sift all such, have some in a box by your side and, as each young plant is dealt with, place a small quantity round the roots. Apply water at once. The planting should be firm, not pressing hard on the roots, but around them and a gentle pressure to the soil immediately on the roots. Whether growing in boxes or in beds in frames the soil should be thoroughly watered a few hours before the plants are lifted, then it will be possible to transfer a neat ball of soil adhering to the roots as well and this means continued progress instead of a check. Slugs always attack newly-planted annuals more persistently than those that are raised in open border, because the soil is loosened round the young specimens and the tiny slugs lodge there, often eating away the tender stems below soil surface and thus remaining unseen. Scatter soot or lime around the plants, but not on them. A small quantity and frequently, does more good than one big dressing. Asters, ten-week stocks, zinnias, African and French marigolds, petunias, nemesias, cosmeas, schizanthus and verbenas are some of the principal kinds to plant. Cosmeas if growing now singly in small pots, may be planted in the pots, just burying the latter, then the plants will flower sooner and for a longer period.



PLANTING OUT CALCEOLARIAS.

Shrubs and Hedges.

SHRUBBERIES, hedges and trees of the evergreen species may be trimmed in July, if they have been making a strong or straggling growth. Whether to use a knife or shears will depend upon the size of the foliage. Shrubs with large leaves are best trimmed into shape with a sharp knife. In this way the foliage will not present such a mangled appearance as when shears are used.

Hedges of yew, privet and other small-leaved shrubs can be clipped with shears. Even when closely cut, the foliage will not look unsightly.

Boxwood edgings should, of course, be trimmed with the hedge shears. If cut too late in the season, the box edgings are likely to become brown for some time, if the weather is hot and dry. If clipped moderately early, a fresh growth may begin before the summer drought sets in. Old woody stumps should be removed with a knife.

Lawn Mowings.

IN hot, dry weather it is not a bad plan to allow the fine mowings to remain on the lawn after cutting, as these will act as a protective mulch and prevent scorching. The plan is really effective for it is just after cutting that scorching is most likely to take place. Lawn mowings make a fine mulch for spreading round fruit bushes, in the strawberry bed and elsewhere in the garden. Spread among young carrot or onion plants they will help in the fight against the "flies" that attack these crops; any insecticides which may have been sprayed over the lawn mowings will retain their virtue for a long while. The mowings may be dug into the soil to open it up and enrich it and they can be added to the manure heap to eke out the supply of the material.

Early Eradication of Rose Pests.

THE spraying of roses ought to begin early in the spring. Already THE GARDEN has mentioned the good effect of several sprayings with dilute formalin and we merely wish to emphasise the matter by extending the principle a little farther. Too "forcing" manures often encourage disease and, on the other hand, starvation may be equally bad; our roses must be grown in a rational and kindly way. Bushes inclined to disease constitutionally may, with advantage, be hard pruned—pruned so that sun and air may obtain free access. Weather is also a factor to be considered, for alternating mild days and chilly winds do a lot of harm in encouraging mildew: unfortunately, we cannot run the weather to our own ideas, but we can, at least, watch for the first signs of disease and act, or, indeed, act without waiting. Insect pests never assume virulent proportions on roses sprayed early; hoeing the soil around bushes is also very helpful and the dewing of plants in droughts, with a touch of some insecticide in the water, also goes a long way towards immunity. Growers who are usually troubled in summer should now invest in a small tin of lime sulphur (for diseases) and a bottle of nicotine (for insects); it is often carelessness that lets the troubles become serious and the presence of these washes makes one watchful and prompt. Other sprays may, of course, be preferred, but, by realising facts, every grower should be able to record a season in which his roses were free from all parasites. Roses which are clean produce a greater number of blooms.

WHAT TO SEE AT CHELSEA

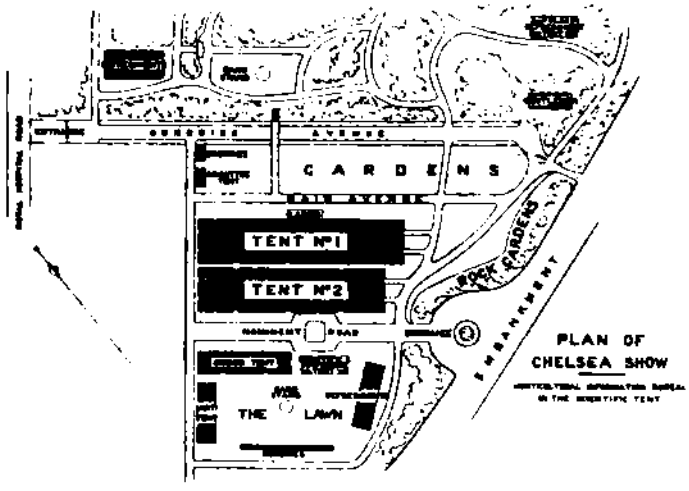
The Show opens on May 25th and remains open until Friday evening the 27th.

THE Chelsea Show, from the position that it occupies as the premier horticultural show in the world and as the culminating peak in the gardener's year, needs no introduction to the majority of our readers. On the other hand, there may be many who have never visted Chelsea, and it is for these that we call attention to a few of the items for which one should keep a look-out on a visit to the Show.

Every amateur gardener, if he can possibly spare the time, should make a point of visiting the Show. Not only is it the finest collection of flowers in bloom to be seen anywhere, but it ranks as part and parcel of one's gardening education. It provides an excellent opportunity of studying plants at first hand and appreciating their merits or discovering their demerits. It permits of comparisons between this and that type of plant or between varieties of the same plant which are not possible on other occasions, since seldom, if ever, is such a collection brought so closely together as at Chelsea for display purposes. Not the least important part of Chelsea is that it allows the visitor to make a selection of plants for his garden, and to order and purchase those which will prove successful in his particular soil and situation. Although it is not the season of the year when gardeners, especially amateurs, wish to be bothered with the plant or seed order for next year, it is important that attention should be given to this while on a visit to Chelsea. There is no need to rely on glowing catalogue descriptions when selecting and purchasing plants Visit Chelsea and see them in the flesh, and order accordingly with discrimination and with an eye to your pocket. If it is thought too early to order, then do the next best thing and take full notes of plants and other items which strike you as likely to be of service to you in your gardening duties. These personal notes and impressions will greatly assist you when making out the gardening order in the autumn. Combined with a catalogue, they will jog the memory, recalling impressions of the many fine things which were seen at the Show. It should be borne in mind that when a definite order is given, few of the plants and seeds can be delivered for several months, Only in the case of irises, alpines, dahlias and a few others can immediate delivery be expected. But early ordering means early delivery and, in turn, early planting, which will help in the autumn in getting the garden re-stocked and new plants established before the onset of winter.

On the whole, too, it is better to order from the exhibitors at Chelsea, as then the respective nurserymen can gauge the demand for a particular plant and regulate the supply accordingly from orders received at the Show. If these are low, then he may underestimate, with the result that the stock runs out and orders received later in the year cannot be met. It is in this way that the regulation of supply and demand, sometimes so acute in the gardening world, can be arranged to everyone's satisfaction if orders are given early. Remember that Chelsea is a flower show at which to buy, as well as to look at and admire.

It is a little difficult, in view of the excellence and variety of the exhibits, to advise the visitor as to what to include and what to omit in his itinerary of the Show. The best way is to decide to see everything and drift with the crowd. Have a quick walk round, thereby gaining a general impression, and then return and examine exhibits of your favourite flowers more leisurely. By that time, no doubt, you will be ready to retire, weary and footsore, but satisfied that you have seen everything worth seeing from your own standpoint.



VISITORS SHOULD MAKE A POINT OF LOOKING OVER THE OUTSIDE EXHIBITS BEFORE BEGINNING THE INDOOR DISPLAYS.

There is no other show in the world which can provide such an attractive display or exhibit more tempting wares to the purchaser as a flower show; and at Chelsea, where things are done on a huge scale, the display is magnificent. Indeed, a general complaint to be heard on every side at the Show is that these things can never be in a small private garden. Amateurs are swamped by the splendour of the trade displays and by their number and variety, and leave the Show feeling disgruntled and dissatisfied. But do not let Chelsea dishearten you; rather let a visit stimulate you to further effort, determined if possible to emulate some of the exhibits staged. Remember that much patience, time and money have been expended by the nurserymen in the production and staging of these exhibits, more so than is possible in the case of the amateur. These displays stand as ideals at which the amateur should aim. That they can be accomplished on more simple lines there is no doubt, and that thought should encourage all amateurs while going round the exhibits.

Chelsea has much to teach apart from the actual display. It brings new plants into prominence and introduces many which have long since gone out of popular favour and which may be unknown to many visitors. The eremuri are a case in point. Last year the exhibits of these tall, handsome subjects excited considerable attention and admiration. It serves to illustrate the wide range of plants which exist to suit all conditions and all gardens. Shrubs, herbaceous plants, rock plants, bulbous plants, greenhouse flowers, orchids—all are there and shown to advantage. In many instances the exhibits indicate to the critical observer and keen gardener how the plants should be grown, and in this way stand as a valuable object lesson to the amateur in showing what to aim at in cultivation. In the rock and formal garden sections this is a point worth noting, and, while a few of the exhibits may lead one astray, in that several plants are introduced solely for the effect of creating a bright display, the majority teach how the various alpine plants are best grown and situated, and how a skilful and simple design of the garden makes for its charm and beauty. When walking round, and any points arise on which advice is sought, never hesitate to ask the attendants. They will be only too willing to supply the

THE ROCK GARDENS SHOULD ON NO ACCOUNT BE MISSED WHEN VISITING THE SHOW. *Many of these are simple designs which can well be carried out within the limits of a small garden.*

THE FORMAL GARDENS ARE ALWAYS ATTRACTIVE.
They suggest lines of treatment to make a small plot effective and beautiful.

necessary information and help you with advice gained by years of practical knowledge and experience. Chelsea exists from year to year to assist not only those who are keen gardeners already but those who are only just beginning to garden. The ideas of the amateur who has just commenced his gardening education may be nebulous to begin with, but after a visit to Chelsea they will slowly but surely crystallise and gradually he will find himself becoming expert in that particular branch which has attraction for him.

If you have not visited Chelsea, do so this year. There is a spirit of attraction in the Show. It is not a fashionable parade. It is an educational display which has for its object the stimulation of the love of flowers which is inherent in every one of us.

On entering the Show, the rock and formal gardens call for first examination. This year the formal gardens constructed are varied in design.

In the main avenue, on an angle site, Messrs. Pulham have built an attractive formal garden. It consists of a raised York stone terracing from which a series of columns arise. These are uncommon in design, consisting of alternate York stone and red tile courses, and are surmounted by sawn oak timbers, forming a pergola on which climbing roses are trained. The terrace is reached by two short flights of York stone steps which are led up to by paved paths from different points. At one point the terrace breaks into an octagonal angle, the rim of which is raised, and here a small pool is introduced. Around the court beds are planted with polyantha roses, and the turf in the outer portion of the exhibit is also set with beds filled with roses. The side borders are planted with hydrangeas, delphiniums, anchusas and other herbaceous plants.

Messrs. Hodson's of Nottingham are exhibiting a miniature formal garden planted with flowering and ornamental standard and bush shrubs. In this garden is shown a new type of hard tennis court, green in colour, requiring no attention or upkeep and unaffected by frost, rain or snow.

The principal feature in Messrs. Carters' garden is a fine Italian temple surrounded by plantings of rhododendrons. The setting of this garden, being raised above the general level, is very effective. The planting is chiefly at the sides and rear, leaving a sweep of grass and an uninterrupted view

THE INDOOR EXHIBITS OF ALPINES HAVE MUCH TO SHOW IN THE WAY OF HARDY ROCK PLANTS AND NOT A FEW NOVELTIES.

IRISES FORM A PROMINENT FEATURE OF THE SHOW.
They are in full flower now, and can be planted during the summer.

through the centre. Two pools, one on each side of the garden, make a pleasant break. A most attractive walled-in garden is laid out by the Horsecombe Quarries and Stone Works. In the centre is a sunken garden with, as a focus point, a small lily pond. Balustrading surrounds the front and gives a fine finish to the exhibit.

In the formal garden section Messrs. Suttons stage a novel exhibit which is sure to attract the attention of all who are interested in the formation and upkeep of bowling greens and tennis courts. The exhibit takes the form of a miniature bowling green and tennis court, and they have also constructed a miniature lawn tennis court of a new type which requires practically no upkeep. Visitors should make a point of looking at this exhibit.

Among the rock gardens there are many attractive lay-outs which should be noted. Mr. George Whitelegg's garden takes the form of a mountain stream descending through a gorge of Cheddar limestone, finally coming to rest in a pool at the base of the garden. The rock outcrops, all well placed, are planted with choice alpine plants, saxifrages, phloxes and hosts of others all suited to their various positions.

That of Messrs. Hodson's is on a more lavish scale. It is of a weather-worn Westmorland limestone, with pools and waterfalls.

Digitized by Google

The crevices between the rocks and the stretches of a fine lawn are planted up with alpines in variety and dwarf shrubs. Among these are to be noted the late-flowering mossy Saxifrage Douglas Haig and the red Hodsonii, phloxes, drifts of Daphne Cneorum and Genista hispanica, Dianthus alpinus and many dwarf conifers.

Messrs. Pulham's rock garden is not so large as usual this year. The stone used is Westmorland limestone, and the outcrops are planted up with a wide selection of alpines. A narrow stream enters at one corner and winds down to the lower portion of the exhibit.

There are many other rock gardens laid out by experts, and each one is worthy of the attention of every visitor to the Show. While many may seem arranged and planted on a much too extensive scale for the amateur to follow, it should be borne in mind that the exhibits only indicate what may be done with rock plants.

Collections of herbaceous plants are always seen in large numbers at this great Show, lupins, irises, delphiniums and other early summer perennials being well represented.

THE EXHIBITS OF HERBACEOUS PLANTS FORM THE BACKBONE OF THE SHOW.

Every amateur should look over the display critically and make a selection for next planting season.

GREENHOUSE FLOWERS, EXHIBITED BY OUR LARGE SEED FIRMS, PROVIDE A PERFECT BLAZE OF COLOUR.

varieties, while Coralina, Mollie and Lena are three good sorts for baskets.

Messrs. Oliver and Hunter have an exhibit which will be of great interest to the lover of primulas as well as the rock garden specialist. Many new Tibetan species which have been recently introduced, such as P. Florindæ, P. microdonta and P. Waltoni, are represented. Primula Geraldiana alba and P. tsargonensis, belonging to the muscarioides section, are also among this group.

A collection of alpine plants backed by many choice and new varieties of brooms, Japanese maples and other dwarf shrubs is staged by Messrs. Bowell and Skarratt. Several uncommon lewisias, trilliums, alliums and tulip species, and Viola gracilis sulphurea are noted. Another table rock garden which is of particular interest is that of Mr. W. E. Th. Ingwersen, who has chosen for a background fine specimens of the rare Cupressus leptoclada and similar slow-growing conifers. Saxifrages, primulas, phloxes and hosts of

Some of the finest new lupins are among the group of hardy plants shown by Messrs. J. Waterer, Sons and Crisp. Sunshine, Delight and Pink Pearls are three of the most attractive varieties which can be seen. Rhododendrons, including Prince of Wales, a striking novelty; azaleas, flowering ornamental shrubs and an exhibit of alpines are also staged by this firm.

Those who do not know the famous Wrexham strain of delphiniums should make a point of examining Messrs. Hewitt and Co.'s stand, where many varieties are on show. Rose Marie, Great Strides and Ruffled Beauty are three of the newest of this type.

Large and handsome spikes of delphiniums in vivid and striking colourings can be seen on the stand of Messrs. Blackmore and Langdon, a firm which has raised many excellent new varieties. Included in this comprehensive collection are such varieties as Millicent Blackmore, Sir Douglas Haig, Mrs. Foster Cunliffe, Blue Queen and Constance. This firm has also a very fine group of begonias, some varieties of which are adapted for growing in baskets. These begonias are all in soft and yet glowing shades and they make a beautiful display. Brian Langdon, Mabel Langdon, Lady Ann and Mrs. D. B. Crane are a few of the most attractive double

THE DISPLAYS OF SWEET PEAS CANNOT FAIL TO ATTRACT.

They are always magnificent in their colourings and appearance.

Digitized by Google

choice alpines can be seen flourishing in the crevices and pockets between large blocks of richly coloured weathered sandstone.

Two exhibits which are particularly worthy of notice are those of Mr. Amos Perry and Mr. H. J. Jones. The former has included some of the finest ferns and a number of new seedling irises in his group, while among the magnificent collection of hydrangeas shown by Mr. Jones are several new seedlings raised by the exhibitor himself.

Roses, carnations and sweet peas occupy considerable space in the tents. Mr. E. J. Hicks has a large and representative group, comprising pot-grown plants of the leading varieties of hybrid teas, teas, polyanthas, etc. Messrs. B. R. Cant, Limited, have a splendid collection, including twelve seedling varieties of their own raising, among them being the new Cecil, Mrs. Beatty and Lady Wakefield. Orange Perfection is a striking new dwarf polyantha rose which is displayed on this stand.

Messrs. A. J. and C. Allen of Norwich are exhibiting cut and pot roses, consisting of specimen ramblers in variety, including Yvonne, Paul's Scarlet Climber, Excelsa and Ille de France, a novelty which is an advance on Hiawatha. Numerous dwarf polyantha roses, a section in which this firm specialises, showed the considerable advance which has been made in this attractive class during the past four or five years. Golden Salmon, a most attractive novelty in a most distinct and pleasing colour, of which its name is indication. Hybrid teas were represented in popular sorts, and many good novelties are also noted. Messrs. Allen are also exhibiting cut flowers of the striking new Gaillardia Tangerine, a noteworthy addition to the herbaceous border.

Two good new seedling roses, Mrs. S. F. Harvey Cant and Mrs. E. Caxton, are to be found in the rose group of Messrs. F. Cant and Co., who have selected for exhibition the leading new varieties as well as many old favourites.

The carnation exhibits add to the floral display. Vesta and Sunny are two outstanding novelties in Messrs. C. Engelmann's magnificent group, which contains nearly twelve thousand blooms. Messrs. Allwood Brothers' carnation exhibit cannot fail to attract attention, for it occupies a prominent position, is well staged and contains all the best varieties under cultivation, both in perpetual-flowering carnations as well as border carnations. Several of their new Allwoodii pinks should be noted.

The richly scented Sir Philip Sassoon is one of the principal varieties in Messrs. Stuart Low and Co.'s group. This is really a giant reincarnation of the old clove. The uniquely coloured violet-purple Sybil and the ruby red of Ruby Glow are conspicuous; while the perfume of Fragrant Rose is what the carnation world has been aiming at for some years—a development in scented varieties.

Another carnation group, which includes some of the best of the modern varieties, has been put up by Messrs. Keith Luxford and Co.

GREENHOUSES OF ALL KINDS AND TO SUIT ALL PURPOSES ARE SHOWN AT CHELSEA EVERY YEAR. HERE IS A TYPE SUITABLE FOR A SMALL SUBURBAN GARDEN.

Each year at Chelsea Show Messrs. Sutton and Sons have an exhibit which is outstanding and always commands much attention. This season their exhibit is a striking one and is carried out on a large scale. The group consists entirely of salpiglossis, one of the most showy and charming of all half-hardy annuals. There are almost fifty different varieties in this group and the plants range from dwarf varieties about 1ft. in height, to tall, stately plants almost 8ft. tall. Many new and beautiful shades can be seen and the colour of some of the varieties is most uncommon. This firm has also staged a comprehensive collection of vegetables, which includes practically every vegetable in and out of season.

Messrs. Edward Webb and Sons, Limited, have arranged a wonderful group of greenhouse flowers raised from seed—banks of calceolaria, cineraria, hybrid schizanthus, gloxinia and Primula obconica. The plants are of excellent form and glorious colourings, exemplifying in a marked degree the perfection of this firm's strains. Annuals in pots—including nemesia, linaria, clarkia, ageratum, alyssum, rhodanthe, dimorphotheca, salpiglossis, etc.—are other items of interest.

Messrs. Carters' exhibit in the main tent takes the form of one huge group, each subject being planted in big blocks, having as the background a feathery band of bamboos and a number of palms. The tall Rehmannia angulata is used as a central feature, while among other subjects forming the back of the exhibit are Clarkia Brilliant Princess and Scarlet Queen, cinerarias, schizanthus and salpiglossis. Imposing groups of their well known strains of calceolarias, begonias, nemesia, Cineraria Brilliant Prize are also included, and in the centre is a large bank of their Gloxinia Invincible Prize. Brompton stocks are also used in variety. No gardener should miss this exhibit, for it is well staged and contains many fine plants raised from good strains. In another tent Messrs. Carters have a separate special exhibit of sweet peas.

The grower of sweet peas should look among Messrs. Dobbie and Co's sweet pea group for Prince of Orange, a novelty of uncommon colouring. Its effect is quite dazzling. Other outstanding varieties are Pinkie, a rose pink pea of the Hebe type; Sunkist, an exact replica of Youth on a cream ground; and Hero, a charming shade of deep reddish rose. There are a number of tulip novelties among this firm's tulip group.

Messrs. Laxton Brothers, the famous strawberry specialists, are, as usual, exhibiting a collection of strawberries in pots and gathered fruit. These include Duchess of York, a new maincrop variety, The Duke, Laxton's Prolific and Majestic. No fruit grower should miss Messrs. Thomas Rivers' exhibit, for it is of educational value. The pot-grown fruit trees bear evidence of good culture, for they are fine specimens, carefully trained, clean and cropping well.

Excellent examples of topiary work are on show and are exhibited by Messrs. John Klinkert, the well known topiarists, who have done so much to bring this class of work to a state of perfection.

In the grounds outside the tents, Messrs. Hillier and Sons are exhibiting conifers, while inside one of the tents they have a large group of ornamental flowering trees and shrubs. Among these there are various brooms, wistarias and many new Japanese and Chinese cherries and crabs.

Orchids of all kinds are always one of the items of interest at Chelsea, and this year they are exhibited by several of the leading growers. Cattleyas and their hybrids are the outstanding feature of Messrs. Stuart Low and Co.'s group, and among these the variety Lord Lambourne, which received the award of merit on the 10th, stands out with its gorgeous golden throat and deep purple lip with its halo-like sepals and petals of rosy lilac. That easily cultivated plant the cool orchid, notably cymbidiums, odontoglossums and odontiodas, are well represented.

Apart from the floral displays, one of the most important features of the Show are the exhibits of horticultural sundries. These, as can be seen, are countless in number, and among them are all the recent horticultural inventions, the most up-to-date types of greenhouses and boilers, the latest samples of garden ornaments and furniture, as well as tools and spraying and mowing machines for every purpose. The progress of science in horticultural matters of all kinds is clearly seen at Chelsea, especially in connection with plant foods and sprays for combating fungoid and insect pests. New and more efficacious fertilisers and spray fluids are on show, and every gardener should make a point of getting full particulars of any of these materials which are likely to suit his especial requirements.

Among the exhibits of greenhouses there are structures which are adapted for general

Digitized by Google

purposes in the amateur's garden: large houses which could be used as cool conservatories and houses suitable for growing tomatoes and chrysanthemums on a small scale. Messrs. Messenger and Co. are exhibiting an excellent conservatory which is well constructed and made of the finest material.

Heating apparatus of various types is also on show. Messrs. Charles P. Kinnell and Co. have a great variety of boilers, and among them the "Horse Shoe" Boiler Apparatus which is suitable for a small greenhouse. This firm is also exhibiting the "Norwich" Valve, which should prove of great service in any garden. Unlike the ordinary tap, it has a full-size waterway consequently, a greater quantity of water is emitted in a shorter time, and this saves the gardener much time in watering.

Messrs. R. Melhuish have a large display of tools and sundries of every description. One of their newest implements is a draw-cut pruner, which cuts as a knife and cannot bruise. They are also specialising in straw mats for the protection of strawberries—a method of protection which is far superior to the old-fashioned custom of placing loose straw around each plant.

Very useful netting supports can be seen on the stand of the House and Garden Sundries Company. The uses of these netting supports are many, and among them are the protection of newly sown lawn grass seed, flower and vegetable seed or strawberries from birds. A new patent metallic wall-plug, seen on this stand, is an excellent device and does away with all the difficulties with regard to securing plants or shrubs on concrete or cement rough-cast walls.

Major C. Walker is demonstrating the value of his Adjustable Wall Tree Protectors, his Transferable Fruit Cage and Bush Tree Protectors. He is also showing every kind of netting, including Walker's Special Frost-proof Netting.

The Papworth Industries have a good selection of garden furniture in natural teak and white enamelled wood. They also have a well designed summer house, and a useful fruit storing cabinet.

Vita Glass and its results in comparison with ordinary glass are being exhibited by the Chase Continuous Cloche Company, who are also including in their exhibit cloches, alpine plant protectors, fruit racks and bulb-drying racks.

On the stand of Messrs. Corry and Co., among numerous sundries is a new material called Corry's Ant and Woodlice Death. This is non-poisonous, and should be of great use in gardens where these pests are troublesome. Weed-killers, fumigants for white fly, and winter washes are also shown.

Furniture of every description as well as new types of bird boxes and feeding trays are being shown by Messrs. Abbott Brothers. Some of these are new in design.

An interesting feature among the sundry exhibits are the nesting boxes for wild birds shown by Messrs. A. H. Moorton, Limited; bird baths, sundials and garden ornaments are also displayed by this firm.

Again this year Messrs. Adco, Limited, are showing samples of synthetic farmyard manure made by the "Adco" process from wheat straw, garden refuse, grass, bracken and hop bine.

GREENHOUSE CALCEOLARIAS & HOW TO GROW THEM

CANDIDLY, I do not think that herbaceous calceolarias appeal to the average amateur, and I venture to say the reason is that they are plants too little understood. As a rule, an amateur's glass accommodation consists of one house, heated in winter, and a cold frame—possibly one or more. In these, he tries to grow a variety of subjects, and in the end finds that all plants are not a success when given the same treatment. Notwithstanding exigencies of space, it is possible by going the right way to work, and studying the needs of these very handsome flowering plants, to have good results. To the one who may not have been successful with them, or, who may have been prevented from giving them a trial because of their admitted tendency to attack from green fly under certain conditions, a review of their requirements from the time seed is sown to their period of bloom, is here set down.

For the amateur, a sowing of seed in June is best, and shallow pans or boxes should be prepared three parts filled with a compost made up of old loam, leaf mould and a good proportion of coarse silver sand; the whole should be thoroughly incorporated and passed through a fine sieve, then made firm in the pan, and the seed—which is very fine—scattered thinly and carefully on the surface. After sowing, scatter over it a dusting of fine soil, quite free from lumps. Cover the pan with a sheet of glass and turn this each day to remove moisture. It is best to place the pan where it can be partly shaded, and at this time (June) bottom heat will not be needed to aid germination. In about ten days the seedlings will begin to appear, when the glass must be at once removed from the pan. As soon as the second leaves show, no time should be lost in pricking off the young plants, and it is best to do so in small pots, as if pricked off into boxes and removal takes place later into pots, there is always the danger with the inexperienced in giving the plants a check. It cannot be too definitely stated that herbaceous calceolarias while in their young state must have shade. This is imperative. It is the absence of shade that causes many promising plants to die off under the hands of amateurs. They must not be allowed to become dry on any account, but should have dewings or sprinklings of water in a tepid state administered from a fine rosed can. From the thumb pots in which the plants were first located to their next stage, about a month will be necessary; then 5in. pots may be brought into use. These pots should be well crocked and over the crocks, coarse coconut fibre, or leaves must be placed, filling up with compost as previously suggested, except that to it a little old rotted manure or bone meal and old soot may be added. In shifting a plant from one pot to another, extreme care is necessary in order that the roots shall not be disturbed at all. When the plants have got over the shift, they can be removed to a cold frame having a north aspect, where air must be admitted freely. Until that time arrives, they must be kept in the coolest part of the greenhouse away from the sun. Once more it is worth while to remind the would-be grower, that shade is necessary to their well-being. Green fly usually attack plants when in a dry and consequently debilitated condition. This should be avoided, and while one ought not to over-water, no plant will grow quicker if given the happy medium of moisture.

Housing the Plants.—By the middle of September arrangements should be made for the transfer of herbaceous calceolarias to the greenhouse. A temperate atmosphere will meet their needs. By this I mean one in which the usual run of greenhouse plants are wintered. The best place for the plants under notice is a shelf not too far removed from the roof, where they will get all the possible light; and the more air which can be given them with safety the better. If a temperature ranging from about 45 to 50 degrees can be maintained, that is all the herbaceous calceolaria wants. All decaying foliage should be removed. Plants must not be packed close together, having regard to the tenderness of the leaves, and they must be given plenty of head-room as the blooming season approaches. Trusses will be much improved if, as the buds begin to appear, the plants are given weak applications of liquid manure, or an approved fertiliser occasionally. Cool treatment, which means progressive growth, should be the aim of the grower, rather than attempt to hurry them into bloom by exciting them in an overheated atmosphere.

OUR PHOTOGRAPHIC COMPETITION

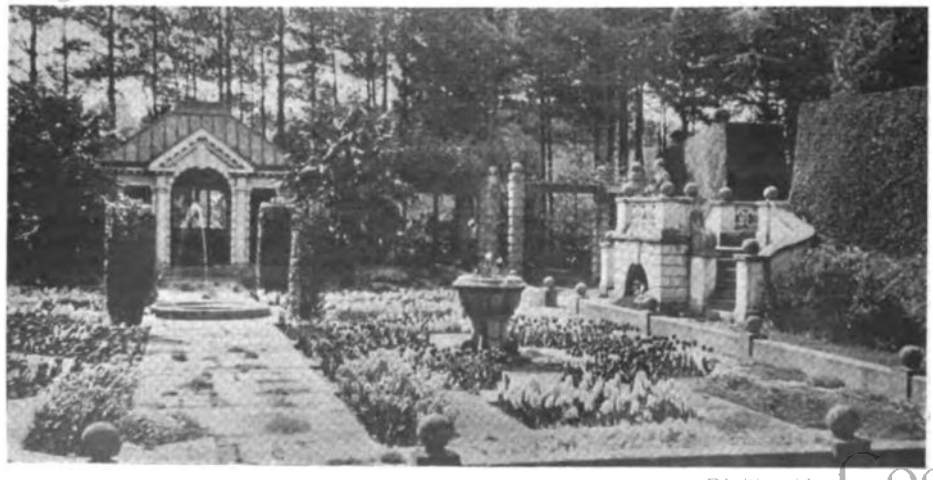
In view of the number of excellent photographs which have been received from readers, many of which are as meritorious from the gardening as from the photographic standpoint, it is impossible to publish as many as we should like. Indeed, it is with no small difficulty that we select those to which awards shall be made. Numbers deserve publication for more than one reason. We propose to retain, unless the senders signify their wishes to the contrary, a selection of the more attractive photographs and to publish them from time to time, independently of the weekly competition announcement, when awards will be made under exactly the same conditions as if the photographs were published in connection with the competition itself. In connection with the receipt and return of photographs we would direct readers' attention to Rules 6 and 7.

This paved path is always a charming sight during the spring months and from the semi-circular teak seat which is placed at the end one has a very pleasant view of the path and the garden itself. Purple and lavender aubrietias and Alyssum saxatile citrinum, the lemon yellow madwort, are planted at the path's edge, and in between the bold clumps of these, there are cottage tulips of beautiful and distinct colourings. On either side of the path there is a row of dwarf conifers which form a most attractive background for the brightly coloured perennials which trail at their feet. It makes a most attractive corner in the garden for many months of the year.

The Guinea Photograph, sent in by MRS. J. E. VICARS, *Ingarsby Old Hall, Leicestershire.*

This tulip garden was made last October out of our artichoke bed. Two of the beds are planted with Inglescombe Pink, a beautiful salmon pink cottage tulip, and two with the Darwin tulips, Pride of Haarlem, Clara Butt and William Copland. Forget-me-nots have been used to carpet the beds. — MRS. TANNER, *Nailsea, Somerset.* Award of 5s.

This photograph of the rose pergola in my garden was taken last summer. The rambler roses on the arches are of various colours, and in the beds beneath, pinks are thickly planted. Spanish irises, preceded by Darwin tulips, are interspersed among the pinks.—MR. R. M. RYDER RITCHIE, *Barford, Warwick.* Award of 5s.



The accompanying photograph shows my Italian garden in spring. A tall yew hedge 8½ ft. high and 4ft. 9ins. in width divides this portion of the garden from the rest, and curved steps lead down to it. Blue hyacinths, the early flowering apricot tulip, Thomas Moore, and the narcissi Lucifer and Beauty fill the formal beds. Sweet alyssum, aubrietias, mossy phloxes and Erinus alpinus are growing in the crevices between the paving stones, and make a charming spring display. — MR. W. WATHEN BARTLETT, *Burley, New Forest.* Award of 5s.

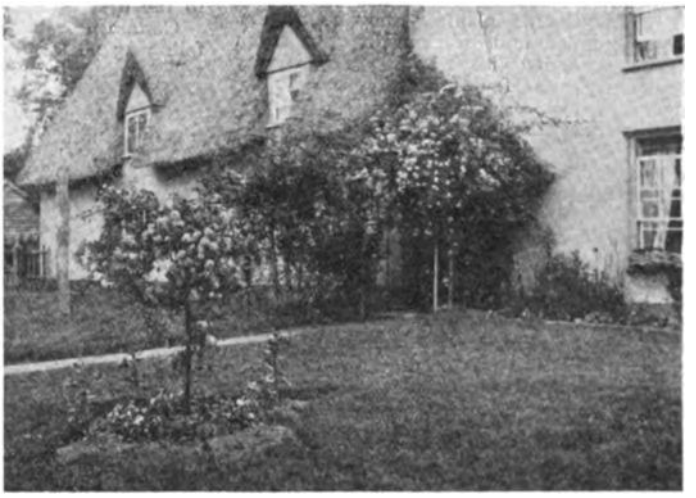
This photograph was taken in April of this year. It shows a rock garden which was a blaze of colour in the early part of the month. The purple aubrietia and pale mauve of the catmint, white candytuft, pink and red rock roses, sprinklings of gold dust, red and white saxifrages and the brilliant blue of the bell-shaped gentian all combine to make a wonderful colour scheme. In a bed behind the rockery are clumps of red, yellow and cream wallflowers, planted out with forget-me-nots. Here and there next to the blue, the bright orange of the perennial wallflower makes a delightful picture. Later on the wallflowers will be replaced by antirrhinums, while most of the rock plants will go on flowering throughout the summer, since a number of the late-flowering kinds have been planted for a succession of bloom.—MISS V. DAVIS, *Crediton, Devon.* Award of 5s.

In this garden wide steps of sandstone lead down to the rose terrace, which is bordered with lavender and standard roses. Thymes, Erigeron mucronatus and Dianthus graniticus are flourishing in the crevices of the flagstones, and the five square beds are filled with the roses Prince de Bulgarie, Mme. Butterfly and Joseph Hill. Beyond the steps, the varieties Betty Uprichard, Hugh Dickson and Mme. Alfred Carrière hang over the yew hedge. Along the trellis above a vine is growing—MRS. CRESWELL, *Ewhurst, Surrey.* Award of 5s.



This photograph shows the rose Dorothy Perkins used as a weeping standard as well as a climber. The weeping standard was budded by myself ten years ago and is still doing as well as ever and when in bloom it looks like a huge shower bouquet. The ground in which it is planted has a gravelly subsoil and it gets no special treatment beyond plenty of water in the dry season. Although this old variety is eclipsed by many of the more modern sorts it is still worth growing.—MR. R. W. THOMPSON, *near Ipswich, Suffolk.* Award of 5s.

This photograph, which was taken during last March, illustrates part of my greenhouse, in which 500 plants of cyclamen have been in bloom since last November and are still in full bloom. It indicates the long flowering period of the cyclamen, which blooms during the dullest months of the year. Good plants can be obtained from seed. The best time for sowing is during August or September.—MR. G. S. LONDON, *West Ferry, Forfarshire.* Award of 5s.

GREENHOUSE NOTES

Bush Chrysanthemums.

How to Treat Them.

CHRYSANTHEMUMS grown to form bushes will bear large as well as small and medium-sized blooms. The plants, in bush form, are splendid for placing on the greenhouse stage or the floor of the conservatory. To be successful in the culture of these plants suitable varieties should be grown. The tall-growing sorts have, as a rule, weakly stems and need the support of stakes freely. The robust, dwarf and medium-height varieties are the best for our purpose. Examples: Mrs. W. Buckbee, Katrina, Huntsman, Cranfordia, Mrs. R. Luxford, Majestic, Mrs. G. Monro, Mrs. Spencer Chichester, Rose Day, Peace, Sulphur Queen, Mrs. M. Sargent, and The Favourite. The amateur cultivator should not attempt to grow specimen plants in small pots—those 7ins. and 8ins. in diameter, or the lower leaves will be lost. The final pot should be at least 9ins. across, a 10in. one being an ideal size. The young plants should be potted on now with a view to placing them finally, late in June, in these large pots. The compost must be one of fibrous loam, a small quantity of leaf-soil, old mortar rubble and bone-meal. It may be that the plants are now about 9ins. high, stopped and bearing three to seven shoots averaging 3ins. in length. It is very important that a few stakes be placed to the plants early so that the young shoots can be made secure to them, thus keeping, at first, the centre open, as this part is sure to fill up in due course. If the young shoots are trained outwards early there is no likelihood of them being broken off later on, when it would be necessary violently to pull them outwards. Throughout, the plants must have an open position and the pots be made secure against the risk of being blown over. To ensure perfect specimens, the last stopping of the shoots must not be later than the last week in June. Also, very close attention must be given to watering and feeding.—GEORGE GARNER.

White (Snowy) Fly in Greenhouses.

How Best to Control It.

AN enquirer in a recent issue of THE GARDEN desires to be informed of a method by which he can control white fly, which infests his greenhouse, and as this pest is all too common under glass, and the small grower is frequently puzzled to know how to get rid of it, this note describes an effective, simple and inexpensive method of destroying it. To a certain extent, fumigating with nicotine, tobacco shreds or similar substances is not very successful against white fly, while spraying with insecticides also proves ineffective. These materials, however, prove efficacious in dealing with many other greenhouse pests.

For many years past large commercial growers of tomatoes, etc., have successfully checkmated this pest by fumigating with hydrocyanic acid (prussic acid) gas. The gas is generated in the houses by dropping a certain quantity of sodium cyanide or potassium cyanide into a carefully measured amount of sulphuric acid or phosphoric acid and water. As there is much danger attached to this method, it is not one to be advocated for use by amateurs.

Potassium cyanide can also be purchased sealed up in zinc containers, all that is necessary being to drop the container into a solution of acid and water, the time taken for the acid to eat through the zinc being sufficient to allow the operator to leave the house and securely fasten the door. This method is quite good, but it entails a certain amount of trouble and precaution in the measuring out of the acid, which is extremely corrosive. More recently a method of fumigating with hydrocyanic acid gas, which is equally as efficient, infinitely easier to apply and, moreover, is quite safe for the amateur to use, has been evolved. I refer to the use of calcium cyanide, which is being marketed under the proprietary name of "Cyanogas" and can be obtained through any nurseryman. Calcium cyanide is in the form of a grey powder, and all that is necessary is to sprinkle it on the floor of the house to be treated and then leave the house, securely locking the door so that no one can enter. The operation should be performed about one hour after sunset, and it will be quite safe to enter the house the following morning, when, if correctly used, all the white fly will be found dead. Repeat after an interval of ten days or a fortnight, in order to destroy insects hatched from eggs which are not destroyed by the gas. The great advantage of this method over the old-fashioned way of fumigating with hydrocyanic acid gas, is that no acids are required, and that the gas is only generated slowly; consequently, ample time is available to sprinkle the powder and leave the house without any danger to the user.

Certain precautions must be taken and the following points should be strictly observed when using calcium cyanide:

(1) Carefully and accurately calculate the volume of the house in cubic feet, by ascertaining the length and breadth and height.

(2) Accurately weigh or measure out the quantity of material required. Start with the lowest dose advised by the makers, and then, if satisfactory results are not achieved and the plants do not suffer any injury, gradually increase the dose until the correct quantity is reached.

(3) Leave as much ventilation on the house as possible until one hour after sunset, then tightly close all ventilators and block up any holes or cracks. If the fires are on, a little extra stoking is recommended, as a rising temperature while fumigating is advisable.

(4) Do not water the plants for at least twenty-four hours prior to fumigation, and no water should stand on the leaves.

(5) It is advisable to pick any ripe tomatoes or other fruit before fumigating.

(6) A certain amount of moisture is necessary in the atmosphere to effect the release of the gas. To obtain this, damp the paths down some little time before sprinkling down the calcium cyanide.

(7) A falling temperature causes water to be deposited on the foliage, and, as the gas may be dissolved in this and result in scorching, the necessity for a rising or steady temperature will be understood.

(8) Ventilate the house as early as possible the following morning, to dry off moisture before the sun becomes at all powerful.—T. H.

Primula kewensis.

THIS delightful member of the popular primula family was, as the name indicates, raised at Kew, the parents being P. floribunda and P. verticillata. It possesses the free-flowering nature of the former—indeed, it is almost perpetual-flowering—and carries the rich yellow flowers of the latter: a happy combination which justifies its fine reputation. In habit, the plant is dwarf and compact; the leaves are a deep green, with rough margins; the flowers are carried on stout stems 9ins. to 10ins. high, in whorls; and they are, as already stated, a clear distinct yellow. Seeds may be sown at this time in a pan of sandy greenhouse compost, containing rather less leaf-mould than is usually mixed in it. Transplant the seedlings into a box of loamy compost, giving them some 3ins. or 4ins. each, and finally put them in 5in. or other suitable pots. When in the pots and established there, keep the plants near the glass; water as required, and give an occasional dose of liquid manure when the flowers are out. At all times avoid a forcing heat; these primulas are coolhouse subjects and they do best when allowed to develop in a natural way. After flowering, old plants may be divided up and grown on a second year—and even a third and fourth—although it is wise to discard plants at the first sign of deterioration, keeping seedlings in readiness to take their place.—LANARKSHIRE.

The Training of Standard Fuchsias.

FUCHSIAS are graceful plants; they bear flowers throughout the summer and early autumn months; they are equally useful for the open border and the greenhouse, and, in both cases, where the plants are grown in standard form, others can be associated with them. The present is a good time to begin the training of the plants; new shoots are growing rapidly, and the best specimens should be selected staked and supported as the growth goes on. Repotting, just at the right time, is very essential, because there should not be any check to free growth during the early part of the summer.

Fuchsias, unlike some kinds of plants, may be practically denuded of their soil in late winter and again be potted into smaller pots, where they are grown under the resting system. So we should try to obtain a strong and rapid growth of main stem now. Recently rooted cuttings will grow and form stems about 18ins. in length during the summer. Plants rooted last autumn, or those one year old, will attain to a height of 3ft. during the current year, bear pinching—stopping—of main shoot at that height and, in addition, produce a number of small shoots which will form the base for the head. Very firm potting must be avoided; the best compost is one of fibrous loam 2 parts, leaf-soil 1 part, old mortar rubble and pounded bricks 1 part. Use coarse sand if old mortar rubble cannot be obtained. To a bushel of the combined parts add a 5in. potful of bone-meal. Make the drainage sound so that water can be freely applied without causing sourness of soil. A cool position, sheltered from strong winds, but not unduly shaded, will be an ideal one for the plants throughout the summer.—HANTS.

Genistas.

AFTER the genistas have done flowering, cut back the young shoots into a shapely head, then stand the plants in the greenhouse or a close frame, and keep them well syringed. Do not allow them to get dry at the root.

When they break into fresh growth, let them have plenty of air. In June place them out in the open, and feed freely with liquid manure. Cuttings taken when the shoots are about 3ins. long may be put into small pots filled with sandy soil. These cuttings root best when kept close, moist, and shaded in a frame. When rooted, they may be potted singly in small pots. Let them have plenty of air when they start into growth again.—J. W.

Watering Pot Plants.

IT is probably true to say that more pot plants are damaged by over-watering than by being given too little. It is impossible to lay down any hard and fast rule as to how much water should be given to a plant in a pot. Generally the idea is to keep the soil just moist, never allowing it to become saturated or dust dry. Give water when

Digitized by Google

the soil shows signs of beginning to get dry, but before it has actually dried right up. Naturally, plants require more water in the summer than in the winter. In the former season water may have to be given once, or even twice a day, while during the cold, sunless months a weekly application may be sufficient. It is important when giving water to let the pot be filled to the brim so that the soil is thoroughly moistened. Then give no further water until the soil shows signs of needing it. The practice of giving a little water frequently is a bad one, as this will, without doubt, result in the souring of the soil. When watering greenhouse plants, strive to have the water at a similar temperature to the air of the house. When, by any chance, a neglected plant has been allowed to get so dry that the soil has contracted round the sides of the pot, a little special treatment is needed. Immerse the pot completely in a larger vessel of water and then, after about twenty minutes, take it out and allow it to drain. Where the soil in the case of a potted plant fails to dry up within a reasonable time, it is safe to conclude that the drainage is at fault. Here, the only safe step is to repot the specimen and re-arrange the drainage system. If this is not done it is quite likely that the plant will die owing to the sour state of the soil.

In a general way, soft-wooded, quick-growing plants require a larger quantity of water than the hard-wooded, slow-growing kinds. Seedlings always need special care in watering, for there is a risk that they may die off from damping. By far the best way is to immerse the pot or pan to the brim in a bowl of water.

PLANT TUBS FOR THE GARDEN

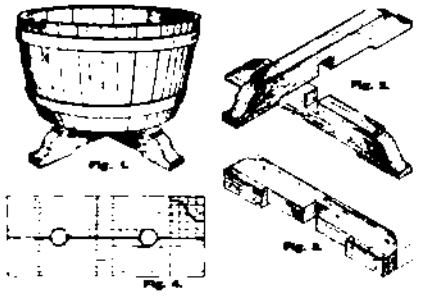
An Interesting Job for the Handyman.

PLANT tubs in oak and other kinds of wood can be purchased ready-made in a variety of shapes and sizes; but those who wish to make them may either adapt barrels or boxes of suitable sizes or make the tubs from new or otherwise prepared timber. There is generally no difficulty in obtaining suitable barrels which are quite free from deleterious matter, or small cases made of wood of substantial thickness; and, as well, suitable wood can be obtained from packing and other cases.

The best method of dealing with a round tub is shown at Fig. 1. The tub or half-barrel is supported on two cross pieces of stout material joined together in the centre as shown at Fig. 2. For a tub of 15ins. or so in diameter, the supporting pieces should be about 2½ins. by 1½ins. The shape of the ends is given as a suggestion but there is no reason why a simpler method should not be used as shown at Fig. 3. To prepare the two pieces shown at Fig. 2, the easiest way is to use a length of 1½in. thick wood about 5½ins. wide. The two holes along the centre line, as at Fig. 4, will enable the under portion to be cut away, and it will be found more convenient to mark the end shapes in the method shown.

The shaped ends should be smoothed with chisel and gouge and finished with file and glass-paper. If the finished work is to be painted, a priming coat should be applied first, or if varnished, the wood must be previously sized.

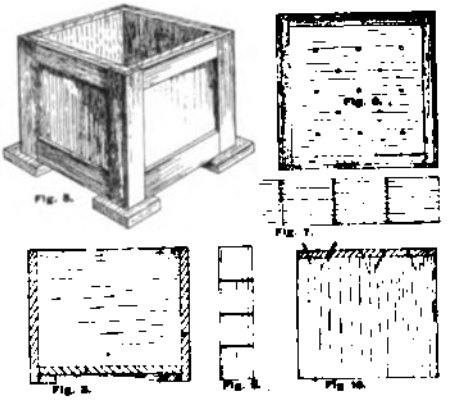
A method of utilising a small packing-case is shown at Fig. 5, the outside of the case



er box being faced with suitable strips of wood. Although it is usual to have square boxes, there is no reason why other shapes should not be used, but it is not a difficult job to cut down an oblong tinned-fruit or similar case to give a square box. The facing should be done with wood at least ¼in. thick, and the edges of the corner pieces should be nailed together in the opposite way to the sides of the box; this increases the strength of the corners. The bottom of the box should be bored with holes at intervals, as shown in the plan at Fig. 6, and then four corner feet should be prepared from thick wood, as at Fig. 7. A square tub can be made from ¾in. wood as shown at Fig. 8; but to give increased strength to the bottom, the latter should be raised ¾in. above the bottom edge, and small squares, as shown at Fig. 9, fitted in the corners before the feet are nailed on. To enable the sides of the box to hold together, the nails should be driven in on the slant, as shown at Fig. 10; this method of nailing gives a dovetail effect to the joint and is very strong.

Another form of square tub is shown at Fig. 11, the interior being a square box made as at Fig. 12. A convenient size for the box is 12ins. each way, and if ¾in. thick wood is used the four corner pieces should be about 1½ins. square in section. The box is supported on rails of similar material to the uprights and tenoned in, as at Fig. 13. The tenons should be ¾in. wide, and the inner upright strips also ¾in. in thickness and about 1½ins. wide, and let in about ¾in. deep. The section at Fig. 14 shows the position of the tenons and slots for the upright strips. When the work is fitted together, the inner box rests on the edges of the bottom rail and under the top rails.

The tub shown at Fig. 15 is suitable for large shrubs, the corner pieces should be about 2ins. square in section; the rails, as shown in the details at Fig. 16, are 1½ins. thick and from 1½ins. to 2ins. wide. The outside boards should be ¾in. thick, and



the bottom formed with strips about 1½ins. by 1in., depending on the size of the tub; they should be spaced about ¾in. apart. The tops of the uprights are easily shaped with a sharp chisel and will give a neat finish to the work.

The tub shown at Fig. 17 is suitable for small shrubs or large flowering plants to be placed in the porch; the handles are provided to make it portable. The section at Fig. 18 shows how the bottom is made, and the plan at Fig. 19 shows the sloping sides. The method of making the two handled sides is shown at Fig. 20; the grooves should be equal to the thickness of the wood used—¾in. is suitable; the total length should be about 18ins., the width across the top 16ins. and at the bottom 13ins. The grooves should be not less than ¾in. away from the edges, and the handle portion 2½ins. to 3½ins. deep. To obtain the shape of the handle, divide the space into five equal parts, form into squares, and then transfer the lines as indicated. The shape of the handle can be worked out with a bowsaw, but if this tool is not available, a few centre-bit holes bored close together will remove all the waste, and the smoothing can be done with a spokeshave. The bottom of the tub, made of strips of wood about 1½ins. by ¾in. in section, is nailed to two stout fillets, as shown in Fig. 20.

THE FRUIT AND KITCHEN GARDEN

Intercropping Lettuce.

READERS who have a very small garden must make the most of it and raise as many vegetables as they can in the restricted space; thus it comes that intercropping is generally advised and frequently practised in such places. The idea behind intercropping is easily understood; a slow growing crop which does not monopolise all the ground until late in the season, has, planted in among it, another crop which matures quickly; the latter is harvested before the former begins to make extensive demands on the space. The same idea holds where a late-maturing crop is planted amid early maturing vegetables. Of all vegetables, the one which lends itself most readily to intercropping is the lettuce. Inside the greenhouse, in early spring, lettuce can be raised between tomatoes in the greenhouse border. Raised as seedlings in spring under glass, plants of lettuce, duly hardened off, may be planted outside in April and May, between cabbages, savoys and cauliflower. Rows of seed may be sown between sprouts and thinned out in due course; lettuce may also be planted out in the shallot border in June and it is common to see them grown between rows of peas and on the ridge of the celery trench. Lastly, a leek border, prepared in April, say to take leeks in June, may be sown down with lettuce when made; leeks can be planted in it while yet the lettuce are there, the lettuce being removed long before the leeks grow large. When intercropping, see that the soil is rich and don't overcrowd; overcrowding defeats its own end and intercropping must not mean such congestion that neither crop is a success.—CLYDESDALE.

Growing Cucumbers in Frames.

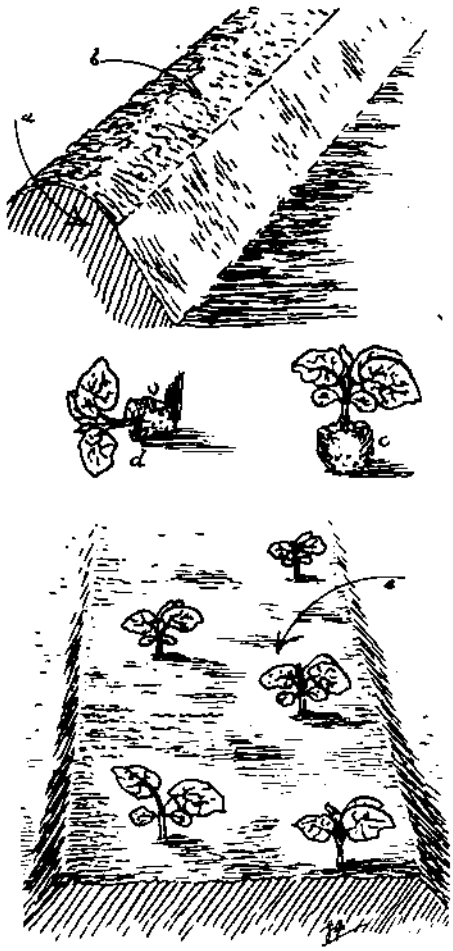
Stop and Pinch at the Right Time.

THE extent to which a cucumber plant will fruit depends to a large degree on the stopping of the shoots at the right time. As soon as the plant has formed, say, five or six leaves, it must be stopped by pinching off the top. Side shoots will then form and these must be encouraged until they show fruit, which is generally after the development of the third leaf. Stop each of the side shoots at the second leaf above the fruit. Now and again the side shoots do not show fruit at the third leaf. In such cases stop the shoot at the fourth leaf and others will form on which fruits will show. These in turn must be stopped at the second leaf above the fruit. All along the new shoots should be stopped in the same way. The plant will rapidly fill the frame with foliage and fruit. After gathering the first crop of fruit, the plant will show signs of exhaustion. At this point good results are secured by cutting away a good many of the older growths that have produced fruits. Other shoots will quickly form and these will, in turn, produce fruit. Even a third crop, somewhat inferior in quality, may be obtained by again thinning the plants after the removal of the second crop. It is an excellent plan to give cucumbers a top-dressing of new soil once a month during the growing season. To keep the soil properly moist when the frame is full of foliage and the plants are bearing fruits, water will be needed two or three times a week. It is a very good idea to let the ordinary watering alternate with applications of weak liquid manure. Soot water is excellent for cucumbers and a very weak solution of guano might be employed with good results. Never allow the fruits to hang overlong on the plants. After they are fully grown, cucumbers rapidly lose their juiciness and their presence on the plant will check the production and development of others.

No shading will be needed after the plants are established, but they should be syringed twice a day in the morning and again in the late afternoon when the frame is closed.—S. LEONARD BASTIN.

Vegetable Marrows and Ridge Cucumbers.

AT the end of May preparations are made for planting out vegetable marrows and ridge cucumbers in the open borders. In the southern counties they may be safely planted on June 7th; in the northern counties it will not be safe to do this work before the



middle of June. The plants must be properly hardened in a cold frame by practically full exposure by day and tilted lights over them throughout the night. Fewer mistakes are made in these days than formerly regarding raised, dry beds in the open air. Sound judgment should be the rule in this matter. If the situation is low and naturally damp, then a raised bed, such as the one shown at *a* and *b* would be the right one to build up, but in normal conditions a low, flat bed, such as the one shown at *e* would be the best. In high, naturally dry gravelly gardens the bed should be of a rich soil formed in a hollow. Soil is dug out forming a long, narrow hollow about 9ins. deep—making a total depth of 18ins.—and good compost is put in to a depth of 1ft. Then the question of compost must be taken into consideration seriously and, along with it the materials for the bed. Usually, strawy litter forms a heap; a few inches of poor soil placed on the surface forms the rooting medium. Now, I would make up the bed without using any strawy litter. Good, well rotted manure and equally good turfy loam, mixed and employed in bulk, rather than sparingly, form the ideal bed in which to grow these plants. Vegetable marrows may be planted 4ft. apart; ridge cucumbers, 3ft. The distances will allow room for free growth. Put in the plants in an upright position as shown at *c*, *c*, and not as shown at *d*. The stems should always be clear of the soil, then there is less danger of decay. The branches will form and can be trained evenly on the surface of the bed.—G. G.

Late May in the Vegetable Garden.

RUNNER beans that have been raised in boxes should be hardened off now and planted out in the prepared situations. The planting should be carried out alternately in double rows, allowing from 6ins. to 9ins. between the plants. Dust the soil round the plants with soot and lime to keep away slugs. It is just as well to put the sticks in straight away and these should stand quite 6ft. or more clear of the ground. Hardened plants of vegetable marrow may be put out on rich soil, although there is no need to set them on manure heaps. About 4ft. should be allowed between the plants. Water frequently and remember that, if the nights are cold, it is well for a week or so to protect the plants with inverted pots. In fairly good soil it is a mistake to add any manure to the position for the outdoor tomatoes, as this induces a rank growth of leaves. A sunny wall is an ideal situation and take care to support each plant with a good stake. The main crop varieties of potato should be hoed directly the rows can be discerned and any hard lumps of soil broken up. In doing this work avoid getting too near to the plants as the roots are easily damaged. Main crop peas should now be sown in well prepared ground. Rows sown earlier are in need of sticks and these should be given at once. For early use celery plants will now be ready for removal from the boxes to well prepared trenches. Water the boxes before taking out the plants and set these firmly not less than 9ins. apart, preferably in single rows. Water in well and keep up an abundant supply of moisture. Further sowings of dwarf beans may be made for succession. Undertake the thinning of all crops which need such treatment in good time. Vegetables which require thinning include parsnips, carrots, salsafy, onions, beet, turnips, etc. Avoid, if possible, thinning when the soil is dry as when it is in a moist state the plants left are not so likely to suffer from the disturbance. Pass the hoe through the rows when the thinning is completed.

Thinning Bunches and Training Shoots of Vines.

DIRECTLY the hot weather comes the shoots of the grape vine grow very rapidly. In a very short time they become a tangle if not properly treated, and then the amateur cultivator feels at a loss as to how he should deal with them. After the vines have flowered, the berries swell rapidly, too, and these are soon spoiled if not thinned out at the proper stage. They should be first thinned when of the size of early, round-seeded peas. Use a forked stick and clean grape scissors. Do not touch the berries with the fingers. Begin at the bottom of the bunch, working upwards, finishing at the shoulders, which may be neatly tied up if they are large. All over the bunch at the points there are three berries and the central one should always be retained. A novice usually cuts it out. More severe thinning may be done near the bottom and less near the top, because there is more room at the

Digitized by Google

top for the berries to swell. First remove the small, non-seeded berries and be sure that they will not be left too thickly near the centre of the bunch. The final thinning out should be done later and before there is any overcrowding of the berries. The shoots, when the vines are in flower, should not be forcibly tied down to the wires as they are, at this stage, quite tough and likely to part from the main rod. When engaged in stopping and tying down the branches, have in mind the fact that the whole of the roof space should be covered with healthy leaves, but in an uncrowded state. Usually it is correct to stop the shoot at two joints beyond the bunch. But if more space must be filled, then stop beyond three joints and just beyond the first leaf on the sub-lateral shoots. Thus, a well managed grape vine should consist, at this stage and onwards, of the main rod, side shoots, sub-laterals and bunches.—HANTS.

Thinning of Fruit.

THINNING of fruit is a necessary operation where the finest fruits are to be obtained. If all the fruits that set were allowed to mature, the crop would consist of small-sized fruits, poor in colour and flavour.

Apples and Pears.—When the fruit is set, thinning should commence. First remove those fruits which are the smallest and ill formed. The second thinning should take place after the June drop, and the fruit should be thinned to one or two fruits per spur. The effect of such thinning will be to give a better colour to the fruit, as well as an increased size, and to reduce the tendency towards biennial bearing.

Plums.—Plums should be thinned at two operations, one when the fruits are the size of a nut, removing the smallest and ill formed fruits, and again when they are the size of a small walnut. This time remove badly shaped and badly placed fruit, and any pairs. The fruit left to mature should be 2–3ins. apart or more, depending on the variety.

Peaches and Nectarines.—Thin at two operations, the size of a small marble and again at the size of a walnut. Leave fruit on the top side of the shoot only, spacing at 9–10ins. apart.

Apricots.—Treat as peaches, but the final distance for thinning should be 4–6ins., according to the variety.

Gooseberries.—Gooseberries can be thinned at several times, starting from the time when the thinnings will be large enough for use as pie fruit. The final distance apart should be 1–2ins. for the finest fruit.

Feeding Pot-Grown Strawberries.

FROM early in May to mid-June amateur cultivators should be busy attending to the bulk of their strawberries growing in pots. It seems to be a very easy matter to feed a strawberry plant growing in a pot. But much care and watchfulness are needed. If a plant becomes very dry at the roots the berries, when ripe, will lose much flavour and also lack colour. The flavour will be impaired if manure water is applied while the soil is very dry. The correct way to feed is to apply clear water first and clear liquid manure about one hour afterwards, before the soil gets dry again and while it is in a perfect state to retain the manurial properties for the benefit of the plants and their fruits. If these conditions are observed, food may be applied daily and on to the full maturity of the berries.—CHRISTCHURCH.

Checking Celery Fly.

AS soon as the celery plants have been set out, steps should be taken to stop the celery fly from laying its eggs on the leaves. Anything that makes the foliage unpleasant to the insect will help to check the pest. Even in districts where celery fly abounds, the crop may be kept free from the pest by syringing with quassia water twice a week and dusting with soot once a week. The treatment must be kept up until the plants are fully grown and are ready for earthing. Where it is evident from the blistered appearance of the leaves that the grub of the fly is at work, a simple means of destroying that particular mischief-maker is to crush between the thumb and finger. Leaves that are very badly affected should be burned.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

AN all too brief spell of delightful summer weather raised the hopes of Scottish gardeners whose work has been hindered by the vagaries of our northern climate; but, alas, they again experienced disappointment, for the high temperature of the week-end was followed by frost on successive mornings and vegetation has received a further check which betokens a late season in various districts of the country.

The young foliage on the rose bushes was developing rapidly after pruning operations were completed, but it has been blasted beyond recovery. The best thing to do under the trying circumstances is to rub off the brown coloured or burned leafage and cut back the stems beyond the point of discoloration. This treatment will encourage the lower buds to break and provide bloom a little later than would otherwise have been the case. Last year when my roses were also frosted about the middle of May I subsequently discovered that the second growth which succeeded the foliage destroyed by the frost went blind and was flowerless during the first period of bloom in June–July. On enquiry I discovered that other rosarians in the west of Scotland had a similar experience, but it would be interesting to know from readers how their bushes were affected.

Sweet pea germination results have been very irregular this season, especially among amateurs who make a practice of sowing the seed under glass in early February. A well known competitor who resides in a county near the Border states that the novelties, eight in number, yielded a full percentage, while in other parts of the country fairly experienced gardeners only got four plants out of packets containing ten and twelve seeds. Another correspondent likens his germination results to a curate's egg which was good in parts. This year I am growing thirty-seven varieties, twenty-five of which are novelties, and the percentage of germination works out approximately at 93 per cent. An analysis of the figures shows that the new varieties of sweet peas have germinated better than the old, and it was the ratio of loss in the latter group that was responsible for the comparatively low average. The seeds were subjected to the same treatment; they were germinated in gentle heat without chipping, but those seeds which were found to be sound were chipped and put back in the soil where they came away later. All the others had rotted. As the result of previous experiments it was found that seeds germinated better in mild heat than those sown in boxes and germinated in a cold frame.

The schedule of the Scottish Pansy and Viola Association, which has just been issued, contains the names of fourteen experts who are to judge the new varieties at the three meetings to be held in Glasgow on July 2nd and 23rd and August 13th. A maximum of twelve points is allowed by each judge, and any variety receiving three-fourths or more of the total number of points is awarded a first-class certificate, while those receiving one-half and up to three-fourths are entitled to a certificate. An important condition which might be followed with advantage by other societies provides that any judge exhibiting blooms is to retire from the room after handing his blooms to the secretary. The following varieties were awarded certificates of merit in 1926: Fancy pansies—McFadyen's Yellow, Doreen Dow and Mrs. Robert Brooks (McFadyen), Mrs. Thomas Brown, John Martin and Dan Cochrane (Cochrane), Jim Harvey (Stevenson), Bailee McEwan (Dobbie). Violas—Abbey Craig, Norwood, Easdale and Fereneze (Howie), Mrs. Jacob Bell, May Gray, and Milton Beauty (McFadyen), Peggy Tennant (Tennant), D. Stevenson (Stevenson), Mary Raeburn (first-class certificate) and Rita Cochrane (Cochrane). The raiser's name is given in parentheses.

A first sowing of French or dwarf beans may now be made in fairly rich light soil. Owing to their bushy habit the plants require plenty of room for development, and the production of satisfactory crops. A foot between each row is not too much, and in sowing in drills 2ins. to 3ins. deep it is a sensible plan to allow for losses by placing the seed 6ins. apart and afterwards thin out the plants to 12ins. This system does not lead to waste, as the surplus can be transplanted to other quarters, but some gardeners favour the alternative method of dibbling the seeds in to the required depth and width. When they are sown too closely, as they often are, the plants cannot grow properly and under crowded conditions there is a tendency to rot off in a wet season. Moisture is essential after the first pods begin to swell, but artificial watering is not necessary when the hoe is frequently used. As the pods become tough if they are allowed to remain too long on the plants, they should be gathered while they are young and crisp. It is only in that condition that they are fit for table use, and the facts should not be overlooked that frequent pulling maintains the productive power of the plant, and a sprinkling of nitrate of soda during growth increases the crop.

In order that a succession of bloom may be available for cutting throughout the summer the annual form of gypsophila should be sown in small quantities at intervals of two or three weeks. When one sowing is made the flowers are past long before the perennial type comes into flower in August, and there is always the danger of wind or rain damaging the slender stems and causing premature decay.

As the planting out season is now at its height in Scotland, here are a few suggestions for the formation of colour schemes in beds or borders of the showy antirrhinum. For beds of self colours Bonfire (orange and flame), Enchantress or Nelrose (pink), Spitfire (orange scarlet) and Golden Monarch (yellow) offer a choice selection; while Mauve Beauty associates with Canary Yellow or White, and Orange Scarlet goes well with Charm (rose pink). A border composed of Tom Thumb varieties in front, intermediate sorts in the middle and a background formed of tall specimens has a delightful appearance, while a distinctive decorative effect may be obtained by using Tom Thumb varieties as a carpeting and planting the tall sorts in rows or irregular intervals in a circular or central bed. ST. MUNGO.

WHAT OUR READERS SAY

A SAXIFRAGA FOR EDGING.

SIR,—It is surprising to me that the very useful Saxifraga Andrewsii is not more generally used. It is what one might term "a good all-rounder," and that qualification merits the keeping of a stock of it in the nursery part of the garden. One purpose for which it may be used is the furnishing of parts of a newly made rock garden where it will be no eyesore or disgrace to the owner until such time as he sees fit to raise or purchase plants of a more aristocratic grade.

Furthermore, if an edging is wanted for a border, S. Andrewsii, in addition to being tidy, is of sufficient vigour to suit itself to the occasion. The leaves, which are markedly serrated, are arranged in such a manner that the whole form a funnel-shaped rosette, the outer leaves being from 2ins. to 3ins. in length.

The flowers are carried in a like manner and are similar to those of the better known London Pride (S. umbrosa). As for the soil requirements, try the soil at your disposal; if S. Andrewsii refuses to grow in it, then I feel sorry for the prospects of any other cultivated plant in that soil.—W. HOWELL, *Dawlish*.

A RAVINE FOR ROCK PLANTS.

SIR,—This experiment, which I carried out in my own garden, may be of interest to a few of your readers.

Feeling sorry for the tiny rock plants, so overshadowed by their tall neighbours in our small town garden, I decided to give them a corner to themselves. A rockery was out of the question; but I thought of the possibility of a "ravine." I dug a trench 12ft. long, varying the depth from 15ins. to 24ins. By adding some good soil at the sides (that from the bottom of the trench was removed altogether), I deepened it in places another 8ins., sloping it away here and there and making it from 15ins. to 30ins. across.

The sides were made secure, irregularly, with grey stones, and some well weathered bricks of delightful shade; these, placed two, sometimes three, deep, were ideal for trailing plants, which I tucked behind and around them as I went on, making pockets for the larger plants higher up and adding a few small ferns on the shady side of the trench. At the end of it, which came up against our neighbour's fence (this was covered with an American blackberry) I planted catmint.

Lilies of the valley, white foxgloves, southernwood and chrysanthemums were already growing round about and will make a good background later on. The bottom of the trench is paved with fairly large stones that I picked up on the beach in the winter; they are fragments of slate, polished by the action of the waves to all shades of grey and blue.

Though only a few weeks have passed since this miniature ravine was made, it is a cheerful little place, occupied by what promises to be a really happy and flourishing rock plant family.—SARAH ROBSON, *West Hartlepools*.

SOUTH AFRICAN CHINCHERINCHEES.

SIR,—During the month of December, 1924, my employer had seeds sent to her from South Africa of Ornithogalum thyrsoides, also known by the name of "Chincherinchee."

These seeds were sown as soon as received, the resulting plants being grown on with warm greenhouse treatment mainly, till about the middle of last month (April), when they came into flower; practically every plant in a batch of about four dozen throwing up its spike, to a height of 2ft. to 3ft., on which the flowers are numerously produced.

The flowers are pure white, with a dark centre and are very effective as cut flowers, in which state they are very durable, lasting a long time in water.

Some time in 1925 we received a further consignment of seed labelled "Ornithogalum spp.," presumably several species of the genus. These were sown and grown in a like manner to the first lot, but the plants have not grown so freely.

Three plants have just recently bloomed, the spikes being much shorter than in the case of O. thyrsoides, and the flowers less numerous, and of a golden yellow colour, very much admired.

The species O. thyrsoides was first introduced to this country from the Cape in 1757, so that it is not a new plant.

It has, according to "The Dictionary of Gardening," two or three varieties, the type being yellow, with white and varying yellow shades in its varieties.—R. DEAN, *Basingstoke*.

THE SLUG PEST.

SIR,—Your correspondent, Cecil M. Bailey, Belfast, rightly calls attention, in your issue of May 14th, to the difficulty of raising eschscholtzias out of doors in autumn owing to the slug pest. This trouble is not common to the north of Ireland or to any particular plant as your correspondent points out. The most disappointing feature of the whole business is that one has been able to do so little to check the pest or its ravages. Lime or soot, particularly the former, help, but only if applied two or three times in succession on a damp night. One dressing is of little use as the slugs are able to throw it off their bodies by means of the mucus or slime which they exude. They are, however, unable to repeat this process more than twice or thrice at short intervals, so that three fair dressings given at dark on a damp night will kill them. I was over in Ireland during April and having the pleasure of meeting some of my gardening friends there told them of my experience with the copper sulphate and kainit treatment recommended as the result of experiments by the Agricultural Department of Leeds University. For a long time I have suffered dreadful damage from huge numbers of slugs. The liming as indicated above reduced them but I could never get free from them. The University advise a combination of sulphate of copper and kainit in the proportion of 1 to 20 or say 5lb. to 6lb. of copper sulphate to 1cwt. kainit, as being deadly to slugs, and the proportion of copper sulphate is not sufficient to damage crops.

I mixed 6lb. of copper sulphate and 1cwt. kainit and used most of it on a little under half an acre of garden land. The immediate effect was marvellous and I advise any reader who really desires to get rid of the pest to do the same. There is no doubt of its efficacy. The best time to apply it is at night when the slugs are on top of ground, preferably on a damp night. There is no difficulty in doing this when the moon is on duty. The preparation appears to have a paralysing effect upon the brutes, which quickly die. It seems that copper sulphate causes the slug to writhe and cover itself with the dressing, when once it touches the upper part of its body.—L. M. MARSHALL, *Worcester*.

DAMAGE BY FROSTS.

SIR,—From reports the effects of the recent frosts have been disastrous in many parts of the country and the extent of the damage is just beginning to be fully realised. It may be of interest to numerous readers to compare notes with this list of shrubs more or less damaged in R.H.S. Gardens, Wisley, with the destruction caused in their own gardens.

In comparing notes I may state we registered the following degrees of frost, *viz.*, on the morning of April 27th, 15 degrees, 28th, 14.8; 29th, nil; 30th, 12.0. These figures are the grass register. The weather station is situated on part of the highest and driest ground in the gardens and I have no doubt from the damage done in the lower part of the gardens that the register would have been much greater.

Collections of pears and apples surrounding the weather station have not suffered extremely as, fortunately, they were thoroughly dry. Gooseberries are left with about half a crop. Black currants on this ground have not suffered so severely as those on the new trial grounds. The early flowers of iris on the trial ground which is lower down were all destroyed, likewise all early shoots of roses in the recently planted rose garden. But it is when we come to examine the shrubs in the wild garden and recently planted shrub garden, that we begin to realise what this means to the display of flower and crop of berries during summer and autumn. Of the large collection of berberis few are left untouched, unless the evergreen section; such varieties as B. Sargentiana, B. Soulei, B. replicata, B. Jamesiana, have the appearance of being scorched with fire, even the accommodating B. Wilsoni and the large collection of hybrids have suffered in many instances beyond recovery for the season.

The majority of the varieties of deutzias have nothing left but brown, withered shoots, the same may be said of philadelphus, viburnums, stranvæsias. Of buddleias the one that seems to have stood the ordeal best is the beautiful B. alternifolia. In the wild garden the early growths of rhododendrons are all more or less destroyed completely, settling the question of flowering next season. We will have to wait for two years before we can see flowers on such kinds as Rhs. decorum, Loderi, sutchuenense, Fargesii and many other species.

Probably the greatest loss at the present time is felt in the azalea garden. These always create a beautiful display during May, and are looked forward to by visitors as one of the chief features of the Gardens for this month. Many will be disappointed this year, as few buds have been left undamaged and much young growth has been killed. Cercidiphyllum japonicum and Hamamelis arborea have suffered the same. As have young growths on heaths, many herbaceous plants, such as astilbe, polygonum, cimicifuga and a host of others, which make a long wearisome list.

Pyrus in many varieties, although in the same exposed positions, have not suffered to any extent, nor have Berberis stenophylla and its varieties, although in full flower during that period. Our only consolation is that all was dry, otherwise our tale of woe would have been longer.—R. F., *Wisley*.

SHRUB NOTES

A Valuable Evergreen Shrub.

ESCALLONIA LANGLEYENSIS is a valuable hybrid derived, according to "Hortus Veitchii," from the intercrossing of E. Philippiana and E. macrantha, sometimes known in gardens as E. sanguinea. It is an elegant evergreen, but occasionally during a cold winter it will lose most, if not all, of its leaves, although I have never known it injured by frosts, even when growing in an exposed position. It will attain a height of 8ft. or more, the general character of the plant being semi-scandent, and for this reason it is seen to advantage if planted on a slightly elevated piece of ground. The slender elongated branches are furnished with small oval leaves of a glossy green, and the bright rose carmine flowers are produced on short, leafy twigs, the whole shrub when in bloom being a glorious sight. The flowering period is extended over June and July, and even later, but in the Chepstow district it is usually at its best in June.

This escallonia is well adapted for walls and fences, but owing to its manner of growth the best effect will not be obtained if it is kept close to its support. If employed as a wall plant the main branches are tied to the fence or wall, and the secondary growths are allowed to develop without any hindrance. This will permit the plant to grow more or less naturally, and its free-flowering qualities and gracefulness will not be curtailed.

When any pruning is needed, it should be done immediately after the flowers are over, and it consists in thinning the shoots and cutting back others that may be encroaching on their less vigorous neighbours.

E. langleyensis is readily increased by cuttings in August if a cold frame is available, while they will also form roots in the open if inserted a month or two later. Like most escallonias, it can also be propagated by layers, which may be done at almost any period.—T. W. B.

Ceanothus Gloire de Versailles.

MANY of the ceanothuses are somewhat tender, but several of the hybrids raised on the Continent from C. americanus, C. azureus and C. ovatus, are quite hardy, especially the one quoted above. Although often recommended as a wall plant, it makes a much finer specimen when set in the open, where there is ample space for development and, moreover, where it can be seen on all sides. Such a specimen is a fine sight during the summer months and although the best display will be in July and August, a few sprays will continue to appear throughout the autumn. This ceanothus will form a well shaped, rounded bush 3ft. to 5ft. high, it is deciduous and will succeed in any good garden soil if afforded a light, open situation. The rich blue flowers are produced in clusters and this delightful hybrid is undoubtedly one of the best. Annual pruning is advisable and this should be carried out in March or early April. It consists of cutting back last year's growth to two or three eyes and by this means the plant is kept within bounds, while strong flowering shoots are encouraged. No doubt it would exceed the height already stated if left unpruned, but this is not advisable, especially in small gardens.

Propagation is effected by cuttings and these will form roots in a cold frame during July or August. A mild hot bed is very useful for increasing this type of plant. So far this ceanothus has not been seriously injured by frosts, and even if it is killed back slightly it is only the wood that is removed at the time of pruning, therefore no harm accrues. A very free bloomer, C. Gloire de Versailles is certainly among the first half dozen of our hardy summer-flowering shrubs and, moreover, it is in bloom when blue flowers are not over plentiful. A most beautiful and desirable shrub.—B.

Some Shrubs to Prune After Flowering.

THE art of pruning flowering shrubs is apparently little understood by the great majority of amateur gardeners. They either prune all in the same manner, during the winter or early spring, as they would roses and fruit trees, or else they do no pruning at all. In either case the best results cannot be obtained. Many shrubs flower during the spring and early summer months, and the cutting back of these early in the year results in the loss of flowering wood.

Shrubs must always be pruned judiciously—in comparatively few cases is it necessary to "spur" them back as is done with many fruit trees—in a large number of cases a careful thinning out of weak and overcrowded wood is all that is required—while certain shrubs, such as magnolias, are better left unpruned, and with others, for example, rhododendrons, it is only necessary to remove any odd, straggly shoot which may spoil the shape of the plant.

It is the purpose of this note to indicate certain shrubs which require attention in the matter of pruning, so soon as the flowers have faded.

Ceanothuses of the spring-flowering section, such as C. rigidus, C. Veitchianus and C. divaricatus, are usually accommodated on walls, these may be spurred hard back.

Clematis montana, another useful wall shrub, should have the old flowering wood removed to the place from which the new growth is pushing.

Cydonia japonica, prune back specimens on walls and trim bushes in the open to keep them shapely.

Deutzias require little pruning beyond the removal of an old branch or so, right down to the base.

Deirvillas (weigelas), remove a proportion of the oldest growths right down to the base and cut away the tips of the remainder to a point from which strong, new growths are appearing.

Jasminum nudiflorum, the flowering growths—other than those required to nail in, to extend the area covered by the plant—should be pruned to within a short distance of their base.

Kerria japonica requires treating in the same manner as the diervillas.

Philadelphus, of the Lemoinei type, may be well thinned out, cutting away the shoots which have flowered.

Prunus japonicus fl. pl. and *P. triloba fl. pl.* both require similar treatment. They should have the growths which have flowered cut back to within 2ins. of the old wood.

Ribes sanguinea (flowering currant) only needs a little thinning out of overcrowded or weakly shoots.

Syringas or lilacs should have the young growths thinned and the faded flowers removed.

Spiræas of the spring-flowering class should be thinned a little as may be required. S. Van Houttei being a good example of this section.

Wistarias may have any shoots not required for extension purposes spurred back several times during the summer season.

Cytisus and *Genistas* (brooms) should have the shoots cut back almost to the wood of the previous year's growth; by this means they are not allowed to become "leggy."—T. H. EVERETT.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints (which should not exceed 150 words in length) is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

The Value of Stones in Assisting Root Formation.

When striking outdoor cuttings of many plants, roses included, I have found the use of flattish stones, pressed firmly about their base excellent in result. Not only do the stones keep the soil in an evenly moist condition, but they prevent disturbance from birds. Shrub cuttings put in a sunny corner strike with great success. In such a situation the warmth keeps life in the cells above ground and the firm, moist earth assists energies below. Recently, when dividing primulas in a bed, the stones came into play. When top-dressing plants in rock borders stones were laid here and there upon the fresh soil. It is, of course, not necessary to retain them permanently. An interesting mesembryanthemum (M. equilateratum), sent me last summer from Cornwall, where it grew wild on cliffs, responded in an extraordinary way to this method. Planted on a sunny slope, it sent out long shoots and flowered in what would have been considered an impossibly short period. Again, a cutting of one of the shrubby veronicas and two shoots of this mesembryanthemum were potted in some fairly light compost in a 3in. pot and three small flat stones were packed on top. Both plants have successfully rooted.—M. C.

Early Tomatoes Out of Doors.

Last year, when I had planted my tomato plants out of doors, I put some old big frames over as many as I could, only putting the lights on at night and on stormy days. I continued doing this until the plants had reached the glass; then I removed the lights altogether, and from the plants thus treated I was able to pick the fruit four or five weeks earlier than from those plants which had to start their outdoor life without the protection of frames.—E. B.

To Make a Good Liquid Infuser.

Procure an old tin with a tight-fitting lid, perforate with small holes, pass a piece of wire from top to bottom the same length as the tub is deep. Fill with the manure required, and stir by lifting the tin up and down by the piece of wire. This prevents coarse pieces stopping up water cans, and the tin does not rot like an old sack.—H. B.

How to Keep Tools Clean.

All practical gardeners know the value of clean tools; but I am afraid that often, at the end of a busy day cleaning is only rather badly finished. Many will call to mind the sand boxes in camp in war-time, where we "cleaned" our knives by pushing them through the sand. Keep a sand box in the garden with some sort of cover to keep it rather dry, and when the rough dirt is scraped off trowel or fork or spade, give the tool a good digging in the sand and you will be able to put it away clean and smooth, ready to work smoothly when required. I have found no cleaning method so quick and handy. The sand can be used for any of the usual garden needs, refilling the box being an easy matter.—N. D.

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

How to Prepare a Frame for Striking Cuttings.

I have a cold frame which I desire to bring into use. What soil and other materials should I require for cuttings and seeds?—H. M., Blackpool.

The frame should be made up as follows: A layer of 3ins. or 4ins. of broken brick and crocks as a drainage layer, covered with a layer of moss and a few leaves, 2ins. to 3ins. deep. This layer will prevent the sand and soil on top from trickling down into the drainage. The final layer should consist of sandy loam, which is rougher towards the bottom, becoming much finer towards the surface, and should be finished off with a dressing of 2ins. or 3ins. of sharp sand. The soil should be on an average from 6–8ins. in depth. This should prove quite suitable for raising cuttings and seeds.

Transplanting Streptosolen and Plumbago.

I have large plants of Streptosolen Jamesoni and plumbago, at present in a greenhouse. I am going to another house, so must move them. Would they grow on a sheltered south wall, or would they want a veranda or other protection of glass?—E. K., Salisbury.

Provided the south wall is sufficiently sheltered there should be no harm in planting out Streptosolen Jamesoni and plumbago. They would do all right in the summer; but for the winter they would need to be transferred under glass, as we do not think they would stand the winter, even in Salisbury, if left out of doors. They will certainly do better if they can have the protection of a veranda.

How to Strike Geranium Cuttings.

Will you kindly tell me when and how to take geranium cuttings (Paul Crampel), and should they strike in a cold greenhouse?—A. R., Birmingham.

The geranium cuttings should be about 5ins. long, severed just below a joint, the leaves from that joint being removed. Insert the stems 2ins. deep in pots or boxes filled with a light, sandy compost. Water once thoroughly, then repeat this operation only just before the soil is getting dry. The cuttings will soon form roots in a greenhouse.

Naturalising Hardy Cyclamen.

I wish to naturalise Cyclamen hederæfolium, or other September-flowering cyclamens, under trees which give a semi-shade: I think they will do there, as they flourish already near-by, but the ground is rather barren and shallow, and I would like to help the roots to grow as fast as possible, as they are naturally slow-growing. I have three or four loads of earth carted from a garden, which can be used, and about a load of leaf-mould. Is there any particular manure which it would be well to mix in? Old mortar rubbish is difficult to get. Possibly ground limestone, lime or bone-meal would be beneficial? And would ½in. of the soil spread over the old soil be enough? I have some hundreds of one-year roots and a less number of two-year.—C. Y,. Newton Ferrers.

If the trees are not pines, the cyclamen should succeed under them. Rich loam 2 parts, leaf-soil 1 part, and well rotted farmyard manure would form a suitable compost, but it should be at least 2ins. deep. Neither lime nor bone-meal need be added to the compost, but should be applied in a year or two's time.

Propagating Border Carnations.

I have one each of a dozen good varieties of border carnations. These I should like to propagate as far as possible, with a view to having a considerable number for exhibition next year. What methods of propagation can you recommend, and when should it be done? I have no hothouse, only a cold frame at my disposal.—R. K., Glasgow.

The best method of propagating border carnations is by layering in July. The dead grass and any weeds found should be removed from the base of the old plants. Some gritty compost should be packed underneath and, after making a slanting cut 1in. long in the stem and about half-way through it, peg the layer into the new soil and keep the latter nicely moist. Roots should form by the end of September.

THE HANDIEST SPRAYER EVER OFFERED!

AND the first to be built on really simple lines. Any and every spraying job can now be done with less material, in less time, and with less fatigue than any other method. It is ideal for all garden and greenhouse work, and by far the best means of lime-washing, creosoting and disinfecting ever invented. So simple a child can use it, yet powerful enough to throw a 40 ft. jet. **Order one now**—it will be sent by return, complete as illustrated, on full-satisfaction-or-money-back terms for

28/6 only.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2896 Saturday, June 4th, 1927 Price TWOPENCE

SALPIGLOSSIS in all colours formed a prominent feature in many exhibits of greenhouse flowers at last week's Chelsea Show, and attracted considerable attention from the many visitors. They are ornamental half-hardy annuals and provide a bright display in beds and borders during the summer, while they are excellent as pot plants for greenhouse decoration. Many of the large-flowered varieties are distinct and attractive in colour and most desirable for the small garden, where they look exceedingly well in clumps in a border. Plants obtained and planted out this month will flower during the summer, or seed may be sown in a cool greenhouse or cold frame from the middle of July until August to produce flowering plants next year.

NOTES AND COMMENTS

Wall and Wayside Gardening.

IN many pictures of English landscape, one notices time and again how the artist brings into prominence wayside and cottage gardens, and makes much of the flowers and plants growing around the homes. These are, in many cases, surrounded by a stone wall, covered with trailing plants in full bloom. Possibly it is aglow with flaming patches of aubrietias, in blue and purple and rosy pink, or white with sprays of Cerastium tomentosum, or iberis (candy-tuft), or that other old-fashioned wall plant, the arabis. One may wonder how it came about that such plants, apparently with little root room, should do so well, and how they came to be there perched up from the road. It may be that in the first instance a few seeds were scattered in the crevices of the stones, or cuttings were stuck about the wall. In the springtime they are a blaze of colour with Cheiranthus in flaming orange, and as they appear from out the crevices one comes to the conclusion that birds must have deposited the seeds. Inside such cottage gardens is probably a flagged path, put down with not much idea of "looking pretty," but for the sake of utility, yet it strikes one as being very delightful, with roots of thyme sprawling across and patches of sweet alyssum at different points. The owner's fondness for pinks and violas and pansies is usually apparent. Clumps of aquilegias and drooping pink racemes of dicentra are also favourites, and flag irises have their place up and down the border. What probably strikes one most is the lack of order, yet the whole aspect of the place is one of beauty. Around the cottage door a familiar, sweet fragrance is noticeable almost before one has ascended the steps, and the bushes of lavender appear as if they must have been planted many years, judging by their thick stems and the abundance of spikes. It is such gardening which has done much to popularise the growing of all kinds of plants and create a love for even the most lowly flowers. Visitors to the country should make a note of the arrangement in these old-world gardens.

Our Photographic Competition.

On page 376 of this week's issue will be found the photographs published in connection with our Photographic Competition. We urge all readers who are interested to send along photographs of their gardens during the summer months.

RULES.

1. All photographs sent in must be taken by the reader or submitted with the consent of the actual photographer.
2. Prints should be on smooth surface paper and preferably in black tones, and can be of any size. Figures may be included where these are helpful to the composition.
3. Prints need not be mounted and negatives must not be sent.
4. The name and address of the sender must be clearly written on the back of each photograph, together with a few explanatory words, such as the names of the flowers, where grown, when planted or sown, or anything which gives point or lends interest to the picture.
5. Each photograph must be accompanied by a coupon, to be found on page xxiii, and a piece of cardboard should be used to prevent damage in the post. Envelopes should be marked "Photographic Competition" on the outside and addressed to The Editor, THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2.
6. A stamped addressed envelope must accompany all photographs. The Editor will endeavour to return those which are considered unsuitable. If this rule is not complied with, prints will not be returned.
7. The Editor wil not hold himself responsible for photographs lost or damaged in the post or otherwise.
8. No correspondence can be entered into.
9. All photographs published will become the copyright of THE GARDEN.

To the reader who sends in the photograph which the Editor considers the best of the week a prize of 21s. will be awarded. For all other competition photographs published 5s. will be paid. Payment will be made about the 7th of the month following date of publication.

The Royal Gardeners' Orphan Fund.

THE annual festival dinner of this national gardening charity, which was held at the Hotel Victoria, London, on Friday, May 20th last, was the most successful of recent years. The Fund was fortunate in having, as chairman of the dinner, Sir Henry Whitehead, who made a splendid appeal for support on behalf of the orphans of gardeners and those engaged in allied callings. Although the appeal realised over one thousand guineas, funds are still needed and we heartily commend this well managed and wholly admirable charity to our readers, who are invited to send donations, which will be gratefully acknowledged by the Secretary, 19, Bedford Chambers, Covent Garden, London, W.C.2.

This Week's Work

For Gardens in the South and Midlands.

Finish planting out all bedding plants and dahlias.
Fill any gaps in the herbaceous border with annuals, dahlias or border chrysanthemums.
Plant out celery, cauliflowers, Brussels sprouts, winter greens, etc.
Earth up potatoes.
Plant out marrows and ridge cucumbers.
Trim evergreen hedges.
Give fruit trees and wall shrubs a light mulch of strawy manure.
Hoe regularly all beds and borders.
Thin carrots, parsnips, onions and turnips.
Sow runner beans, turnips, carrots, beetroot.
Stake perennials in the herbaceous border.

This Week's Work

For Gardens in Scotland and the North.

Sow seeds of auriculas, cowslips, polyanthus and primroses.
Remove side shoots of tomato plants.
Dust gooseberry bushes with hellebore powder after rain.
Plant celery in a double row in prepared trenches.
Sow an early variety of peas for late cropping.
Move late chrysanthemums into their flowering pots.
Earth up second early potato crops.
Plant kale and cabbage for winter use.
Remove pot roses that have flowered indoors to a sunny part of the garden.
Complete bedding out half-hardy annuals.
Clear away soil from shallots to ensure ripening of bulbs.

Digitized by Google

SCENTED EVENING FLOWERS

FOR most of us, the evening aspect of the garden is the one that interests us most; it is only in the cool of the day that we have full leisure to enjoy the fruits of our labour, and what shall we see if we plan out garden from the viewpoint of colour values only? Vivid colours may show up well at mid-day, but in the evening garden fragrance must reign supreme above all other qualities. It is a curious provision of nature that brilliantly coloured flowers possess no scent, for these rely upon their bright hues to attract insect visitors. Fragrant flowers are mostly of soft and subdued tones and, in the case of night-scented species, the colour is usually white or pale yellow, for these shades show up best in the dusk of day.

Let us take a few examples, all plants that may be put in at the present time for providing a profusion of sweetly scented blossom during the summer months.

Nicotiana affinis (the tobacco plant) is one of the most powerfully fragrant of all half-hardy annuals, and is probably familiar to all readers. A big mistake in dealing with this species is to dot the plants about singly. Far finer effects are produced by growing in large masses of six or a dozen, though, of course, this is not possible in a small border. When selecting plants growing in boxes at the nursery, choose only those that look sturdy. Seedlings that have commenced to spindle up to flower in the seed-boxes will never make good plants, though they may blossom very early in the season. N. affinis, of course, bears long tubed white blossoms; besides this, there are the Sanderæ hybrids, with flowers in varying shades of red, pink, mauve, etc., but these scarcely seem so fragrant as the white form. All nicotianas will flourish in partial shade, and in such positions grow very luxuriantly.

A PLANT OF THE TREE LUPIN WILL GREATLY ADD TO THE ATTRACTIONS OF THE EVENING GARDEN.

ONE OF THE BEST OF FRAGRANT FLOWERS.
The sweet-scented stock grown below a window so that its fragrance in the evening can be fully appreciated.

Another fragrant annual is Matthiola bicornis (night scented stock). Seed should be scattered freely in positions where the scented air may be wafted into the living-room. During daytime, the flowers are rolled up in tight balls, but with the approach of evening, or during cool, showery weather, they open wide, and emit their powerful and refreshing fragrance into the surrounding garden for yards around. The double ten-week stocks are also members of the matthiola family, and added to their fragrance, they have the advantage of showiness and ease of culture.

With a fragrance all its own, Schizopetalon Walkerii is an annual that should be far more widely grown than is the case at present. This is a plant that simply must be sown in its flowering quarters, for it is quite impossible to move the delicate rooted seedlings. This also does not open its blossoms till evening, but when it does unfurl its buds, the grower must be prepared for a surprise. The delicate lacy flowers are perfectly *square*, and possess a sweetness quite unlike that of any other flower in the garden.

Of perennial plants, the evening primrose is still a prime favourite, for its beautiful yellow "primroses" show up with startling boldness in the dusk of a summer's night. Though this species is, strictly speaking, of biennial duration only, yet, once it is introduced into the flower garden it will hold its place by means of self-sown seedlings. There are several other delightfully fragrant members of the œnothera family—among the best of these being cæspitosa, with very large white blossoms, 1ft.; speciosa, very graceful in habit, with light sprays of satiny grey flowers; and odorata, an annual species, with bright yellow flowers and growing anything up to 3ft. in height. The double rocket (Hesperis matronalis fl. pl.) is an old-fashioned flower, but owing to its uncertain habits has, unfortunately, waned in popularity. The only way to keep a constant stock of plants is to propagate annually by cuttings, these being inserted on a shady border during summer, for providing flowering specimens for the following year. A moist, rather rich soil will suit this plant best, and in such a position the fragrance will be very pronounced. Border pinks, of course, need little eulogy. Though they are sweet throughout the day, it is only in the evening that one seems to enjoy their fragrance to the fullest extent. Mrs. Sinkins is still one of the finest and sweetest of border sorts, but there are also the dainty single pheasant's eyes, whose charms must not be overlooked. The yellow tree lupin will add greatly to the attraction

Digitized by Google

of the evening garden, though this is a plant that can only be used in large borders, for it will reach a height if quite 6ft., and is often of the same dimensions measured through the bush. There is also a good white variety of this, named Snow Queen, and recently there has been introduced a mauve form in L. Payneii, though the writer cannot claim to have given this species a trial. For edging shady borders, the sweet woodruff has many recommendations, not least of all being its scent, resident both in the flowers and the foliage, and exactly resembling the fragrant breezes blowing from a field of new mown hay. The flowers are produced in small heads, and though not showy, have a delicate grace all their own. Lastly may be mentioned heliotrope, the cherry pie of many districts. This is not a hardy species, and should not be planted outdoors until the end of May, but for the sake of its refreshing scent, it is worthy of a place in every garden. Small plants purchased in pots will flower well during the coming summer, and if desired a few may be potted on to larger pots; these will grow quite well outdoors if they are given a little attention in the way of watering, etc., and will make fine specimens for the hall or dining-room table, where the sweetness will be very apparent. B. D. S.

HOLLYHOCKS FOR NEXT YEAR'S BLOOMING

Seed should be sown this month and the seedlings transplanted to their flowering positions in autumn.

VERY few gardeners trouble to grow hollyhocks nowadays for more than two seasons at the most, because they find that the older the plant becomes the more susceptible it is to the rust disease. The old method of raising plants by means of cuttings is only practised by those who, to carry out a colour scheme, must be absolutely certain that the colours will be those desired. In the mixed border, where certainty of colour is not essential, plants raised from seed satisfy all requirements, and prove very little affected by the rust disease unless grown on, year after year, when they lose the vigour which they possessed as seedlings, and fall a prey to the fungus which produces the bright yellow spores on the stem, and causes all the lower leaves to dry up and eventually fall off.

Gardeners who have heated structures obtain very good results from seed by treating the hollyhock as an annual, sowing the seed in heat in January, and hardening off the plants ready for planting out in May. The hollyhock is, however, a perfectly hardy plant, and it is, in my opinion, a waste of valuable greenhouse space to treat it as a tender plant when much better results can be obtained from outdoor sowings. So hardy is it that seeds which have been self-sown or been scattered when the flowering stems have been cut down and thrown on the rubbish heap, will remain unharmed through the rotting rains and severe frosts of winter, and commence germination in January under conditions to which it would never be subjected by the most careless of gardeners. Such self-sown seedlings, if lifted and pricked off into pans, will make splendid plants for planting out in May, the only protection necessary being that of the cold frame.

It is not, however, advisable to rely upon so haphazard a method of obtaining plants. Seed may be sown all through June, either in shaded cold frames or in the open ground. As the seedlings will be pricked off in the early stages of growth, no special pains need be taken to make a good seed bed, or to space out the seeds in the row, although, as the seed is large and easily handled, this is the recommended method with a choice stock of seed. One can, therefore, either sow the seed broadcast in a small patch, raking over to cover the seed, or make shallow drills in which the seed is scattered. It does not really matter, for, as soon as the seedlings have made the first pair of true leaves, they are lifted and pricked off into nursery rows, allowing at least 6ins. between the plants, which space they will fill before they are ready to lift for the autumn planting into flowering stations in the border. The seedlings can be lifted with an old table fork, and rapidly dibbled into any vacant piece of ground which receives full sunshine, such as the ground left vacant when the early potatoes have been lifted. If the ground is very dry, it should be watered an hour before putting out the seedlings, when the rough clods will fine down if lightly raked. Having dibbled them in, pressing the soil firmly round the roots, they may receive a light watering to consolidate the surrounding soil, and require no more attention beyond hoeing and weeding until autumn.

They should then be plants which delight the gardener's heart. Lovely stuff, with leaves akin to that of small rhubarb, and with a tap root which will require a goodly hole for its accommodation. The plants always seem to do better when planted out in the autumn, any damage to the roots by the lifting being made good by the callus, and emission of new rootlets due to the warmth of the soil, anchors them firmly before winter sets in. If put out too late, or when the ground is cold, frost will sometimes lift them; but I have never found this to occur when plants have been put out in late September and October.

Such plants will produce splendid stems of bloom next year, and still finer in the second year, after which they should be discarded to make way for another batch of seedling plants. As they are gross feeders, the ground should have had a good dressing of rotted stable dung, hop manure or coarse bone-meal dug in when planting new plants over the stations occupied by the old ones.

When the soil is not unduly lacking in humus, I find that the best manure for young seedling plants is a handful of bone-meal dug in before inserting the plant. This rots down during the winter and becomes available for the plant at a time when it needs food to produce those tall stems which make the hollyhock so valuable for the back of the herbaceous border.

During recent years the single varieties have rapidly increased in favour, and, in my opinion, make a better show than do the doubles, which often have their blooms partially hidden by the leaves. The singles also bloom earlier than the doubles, which is an advantage where successional blooming is desired—clumps of both sorts being planted for this purpose. While isolated plants are very pretty in the border, I prefer to plant at least six at a station at 1ft. intervals, especially if seedling plants are to remain only one year in the border. A healthy seedling usually sends up one main spike, unless the top has been damaged, when it may throw two or three shorter stems. In the second year the plants break up into a series of stems, not quite so tall as those produced in the first season, but which make a more effective display in a large border.

Stakes should be provided for each plant, not thin bamboos, which cannot hold the spikes in a gale, but sturdy hazel stakes, 5ft. in height, driven into the ground for at least a foot, and the soil well rammed to keep them firmly in position. Almost any soil seems to suit the plant: I have seen splendid specimens growing between the rails of the permanent way of a railway siding. A heavy clay, the despair of the gardener, will produce spikes of bloom of which any gardener may be proud, while very good stems may be obtained from even a sandy peat, in fact, the hollyhock is one of the most accommodating of all perennials. C. P.

A FINE GROUP OF HOLLYHOCKS RAISED FROM SEED.

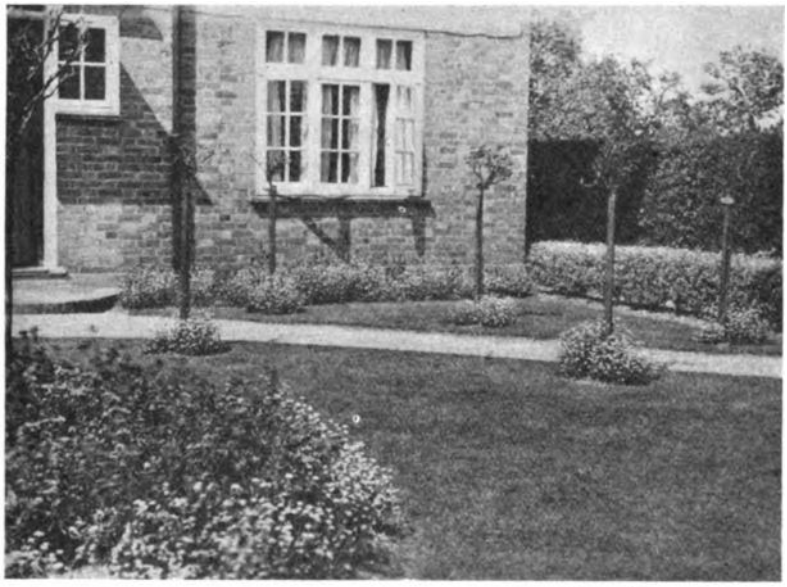
GARDEN FAVOURITES TO SOW NOW

Forget-me-nots and columbines are among the favourite spring garden flowers of all amateurs. They are both graceful in habit and beautiful in flower, easy of culture and suitable for any garden scheme. Seed of both kinds should be sown now in a bed outdoors and transplanted to their flowering positions—in the autumn in the case of the former and in spring with the latter—to provide flowering plants for next year. Every amateur should sow a packet of selected seeds now.

THE idea, which at one time prevailed in the minds of quite a number of amateurs, that forget-me-nots made a fine display in a garden in spring, provided they could be given a moist place, and that, without such conditions, results would be meagre, has long since gone by the board. True it is that some varieties, like the old Myosotis palustris which skirts our streams and rivers in many parts of the country, are in their element when in a moist situation; but there are other sorts which, to a great extent, are independent of an excess of moisture at the roots, that give splendid results when grown in a garden under quite ordinary conditions. To-day, we recognise forget-me-nots as among our most useful subjects for a spring display—so much so, that it has become quite a common practice when planting bulbs in the autumn to finish the work by setting on the top of them these blue-eyed favourites; or, if the planting is not undertaken in the autumn, then opportunity is taken to do so in spring before their growth has far advanced.



FORGET-ME-NOTS CAN BE USED WITH GREAT EFFECT DURING THE SPRING MONTHS AS EDGINGS TO BEDS AND BORDERS.
In this illustration they provide a perfect display in a small front villa garden.

Raising Plants.

The most satisfactory method in getting a stock of plants together is by way of seed, and this can be sown in May or June out of doors in any fairly light soil, and it will often be found that once sowing is generally sufficient, inasmuch as from "self sowings" there are usually enough plants the following year. In pricking out the plants, which ought to be done as soon as they are large enough to handle, it is well to choose a shady place in the garden where they can remain until the autumn. Some postpone the sowing of seed until July, but the objection to this, so it seems to me, is that, not infrequently, hot weather, following close on the time for pricking plants out, losses ensue. That, at any rate, has been my experience, and I prefer the earlier sowing, and to get plants out into a shady spot.

Varieties.

Among the many varieties at present in cultivation there are some with pink and white flowers, but the greater interest centres round those in shades of blue. There is, for instance, a wide range from palest blue to the deep tint of indigo. To-day, most firms of repute cater for the "spring bedder," and in this particular the amateur is not by any means slow to appreciate what a glorious display of "misty blue" a packet of seed will bring, sown the previous spring.

Here are a few of the sorts at the disposal of the grower, and it only remains to be said that forget-me-nots may be grown with as much satisfaction in the suburban garden and around villa residences, as in the pure air of the country.

Myosotis Royal Blue, height 12ins.

M. palustris semperflorens, 9ins., bright blue (Water forget-me-not).

M. dissitiflora, 9ins., much used for massing with bulbs.

M. sylvatica, 6ins., blue.

M. Sutton's Perfection, 9ins., noted for its great output of very bright blue blossoms.

M. alpestris Victoria, 6ins., azure blue.

Columbines.

THERE are few plants to excel in grace and elegance the long-spurred aquilegias, while the wide range of colours displayed in the blossoms leaves nothing to be desired. Even the short-spurred sorts—the columbines of our childhood days—are worthy of garden space, while for the semi-shady part of the wild garden there can be nothing more charming during May and June. All aquilegias are of great value for cutting for they last long in water, and their graceful habit of growth lends them an added beauty in the vase. Groups of five or seven make a bold show in the border during early summer, the individual plants being placed quite 18ins. apart. Specimens growing in partial shade will give the finest blossoms being larger, of a better colour, and lasting longer than those grown in the full blaze of the sun. Spring is the best time for planting out seedlings, and they will benefit if the ground has previously been liberally dressed with leaf-mould and rotted manure: heavy soils should also have a dressing of grit, for sticky, pasty ground is anathema to all but the commonest sorts.

A GRACEFUL LONG-SPURRED AQUILEGIA.
These flowers are useful both for garden and indoor decoration. Seed can be sown outdoors now to obtain flowering plants next year.

Aquilegias are easily raised from seed sown outdoors at the present time, and, indeed, self-sown seedlings usually spring up by the hundred in favourable soils, though these will not give such fine flowers as those raised from a selected strain of seed. It is sometimes an advantage to grow aquilegias in separate colours and, besides the mixed packets, many seedsmen now put up packets containing separate pink, blue, white or yellow shades. A shady border is the best place for the seed bed, and the seed should be sown very thinly, thus obviating the necessity of moving the seedlings to nursery beds. Throughout the summer constant hoeing should be practised, and occasional soakings of clear water given during very droughty periods. Beyond this no special attention is needed, for in all essentials the aquilegia is an easy plant to grow. The main object is to get strong young plants for next summer's display, and no attempt should be made to induce them to flower during the current season. As stated earlier, spring is the best time for planting out, so the seedlings may remain undisturbed until that season. When lifting, reasonable care must be taken to avoid breaking the roots, for this often causes a serious set-back to the plants, and in any case will adversely affect flower production.

Besides the long-spurred hybrids, there are the many extremely beautiful parent species, and these are also raised from seed as described above. Caerulea is exquisite in cool blue and white, and is a favourite plant for the rock garden, though in some soils it is not perfectly hardy. Alpina is another blue-flowered species and, with me at any rate, more robust than the preceding. Rather dwarfer is A. glandulosa, growing about 1ft. high, and also blue and white. Chrysantha is regal in golden yellow, and Skinneri unique with greenish yellow and scarlet blossoms borne over a long period. There are also double aquilegias admired by some, but they do not possess one tithe the elegance of the long-spurred singles, though it is true that they give a quaint old-world touch in the flower border, which may be some reason for their popularity.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Staking and Thinning Border Plants.

The Art of Staking.

MOST of the crops are now planted, and beyond checking insect pests and keeping down weeds there is not a lot to be done in the garden. June is a month of growth and fruition; flowers, early vegetables and fruits are ready. It is the season of the early harvest. As the summer advances our whole efforts must be directed to keeping the garden at a high level of excellence. One of the most important things is to give support to plants wherever it is needed. This is pleasant work. Walk round the flower garden and note all plants that require stakes. Obtain stakes according to the approximate height of the plant when in flower. Tall rudbeckias, some Michaelmas daisies, everlasting peas, and tall lilies need 5ft. to 6ft. stakes; galega, helenium, anchusa need 4ft. stakes; lychnis, pyrethrum, clarkias only 2ft. stakes, and so on. Allowance should be made for the 6ins. or so of the stake which will be pushed into the soil. As a general rule, the stake needs to be about two-thirds of the height of a fully grown plant.

How to Tie.

Having obtained all the necessary stakes, lay them out beside the plants for which they are intended. This saves trouble if a large number have to be done. A plentiful supply of tying material will be required. Use string for or tall, heavy plants, and raffia or green twist for small, soft-stemmed flowers. Hold a committee meeting with yourself over each plant. If it is at the moment only a foot high, but is likely to grow to six feet, put a stake to it and run a string round. This helps it to grow up straight, instead of being bent by the wind. The secret of a well kept border is to stake in time.

The writer's first experience in tying plants is still remembered by the instruction that a clump of Michaelmas daisies is not a bundle of hay. One stake is useless for a big clump of flowers. Three placed trianglewise are better. Run a string round the clump, tying it to the stakes, but leave one stem outside to tie to each stake. This covers it, and the art of staking is to conceal the stakes. When the plants are in flower not a support should be seen. Remember to twist the string round the stake first, and then tie round the plant, loosely enough to allow for growth.

Thinning Perennials.

Herbaceous perennials, such as asters, heleniums and sunflowers make a remarkable number of new stems each year. Some are strong and others weak, and the weakly ones should be pulled out before the plants are tied up. This gives added strength to the stronger stems, and better flowers will result. After staking all the flowers in the border, run the hoe over the soil between the clumps and pull out any weeds in the centre of the plants.

Early flowers, such as wallflowers, are over, and their place should be filled with some quick-growing annuals. Clarkia, Californian poppy and Virginian stock will germinate quickly. A few seedling asters or nasturtiums, petunias or verbenas could be bought and used to fill vacant places.

When roses are grown in a mixed border, take care not to allow other plants to crowd them. Many a charming rose bush is spoilt in this way. At least a clear foot should be allowed all round the bush.

Training Fruit Trees.

FRUIT trees, such as Morello cherry, plums, currants, grown against a wall or fence require training. Young growths appear at an alarming rate, and the fruits may quickly be hidden in a thicket of new growth. If the tender shoots are tied into position while they are pliable, there is less likelihood of breakage. The bunches of fruit are also exposed to the sun, ripening early and gaining a better colour, Cut away "breast wood"—that is, the shoots that stick out at right angles to the wall. Lay in the young growths full length. Special iron nails are obtainable for fastening wall trees. String can be used for tying shoots to railings or fences.

Fruit trees grown against walls are liable to get dry at the roots. A few pails of water poured on during hot weather are a great boon to the swelling fruits. It is a good practice to soak thoroughly all the shoots of wall trees and climbers with clean water after a hot day. This both assists growth and checks insect pests. Stir the surface soil round all the trees, but not deeper than two inches. If manure is available, give a top dressing. A handful of superphosphate of lime sprinkled on the soil round the tree will wash in with the rain and prove useful to stone fruits.

TALL-GROWING DELPHINIUMS NEED TO BE STAKED NOW BEFORE THEY BECOME TOP HEAVY.

Work Among the Roses.

ROSARIANS find plenty to do among their favourites just now. A sharp watch must be kept for the rose maggot, which, embedding itself in the tips of the young shoots, quickly eats the swelling rosebuds. The simplest remedy is to squeeze the affected shoots between the thumb and finger. It can safely be assumed that where two leaves adhere together a grub is doing mischief. Green fly should be destroyed by a timely spraying with paraffin emulsion or an insecticide. Keep down all weeds round the plants. Rose mildew is sometimes troublesome, particularly during a spell of wet weather. This can easily be cured by spraying with potassium sulphide solution, using 1oz. of sulphide to three gallons of water. It is best dissolved in a little hot water before the cold is added.

For the best results, other plants should not be allowed to grow too close. Roses need plenty of air. A carpet of sweet Alyssum or similar dwarf plants beneath rose trees will do little harm, providing the soil is enriched with fertilisers. An excellent stimulant for roses is a mixture of equal parts of sulphate of ammonia and superphosphate of lime sprinkled on the soil during showery weather, at the rate of 1oz. to a square yard.

Hybrid teas and teas give continuous crops of bloom until late autumn. When a hybrid tea rose is cut, the natural result is for the top bud on the stem to develop. If the stem is shortened back at the time of cutting, a stronger shoot will grow. This will result in a better second crop of flowers.

Hybrid perpetuals only give one good crop of bloom, and when this is over shoots spring from the base. If the old wood is cut back, as well as the thin weakly stems, it is obvious that better specimens will result next year. Climbing roses of the "Dorothy Perkins" type benefit from an application of liquid manure while the flower trusses are forming. Care should be taken to tie in all new shoots in order to prevent breakage by the wind.

Summer Bedding.

Colour Associations.

THE glory of spring flowers is over and our gardens must now change their dress for the summer. Tulips, daffodils and other bulbs can be lifted and the soil forked over in readiness for summer flowers. All tender plants can now be safely planted out of doors. In planting a garden, some consideration should be given to the colour of the house and the surroundings. An old red brick house which has mellowed with age may have the association of orange, salmon or coppery-crimson flowers. Nemesias, begonias and warm coloured snapdragons, would blend well, with occasional groups of white—asters, gypsophila, tobacco flowers and chrysanthemums. With white houses, use flowers of bright hues, such as blue delphiniums, Salvia patens, scarlet dahlias and cannas with bronze foliage. Grey stone buildings provide a setting for almost any colour scheme.

In arranging a bed of flowers in a grass lawn, a pitfall to avoid is confusion of varieties. One of the most beautiful effects I ever saw was obtained by a mixture of blue delphiniums with white antirrhinums. Scarlet lobelia (cardinalis) rising through a carpet of grey-leaved Cineraria maritima is equally effective. Another couple which associate well are tall orange red snapdragons in a carpet of white alyssum. Snapdragons are undoubtedly the most popular of bedding plants, because of their lasting qualities. If the seed pods are removed as the central flowers die, fresh shoots spring from the sides. Moreover, this flower enjoys brilliant sunshine.

THE BUSY MAN'S PAGE

June Reminders.

SCARLET runner beans may be sown in well prepared positions, and these will be little behind the sowings made last month.

Set out celery plants.

On a cool border sow lettuces.

Thin out early turnips and make further sowings.

Thin carrots, parsnips and onions.

Leeks may now be planted out.

Plant cauliflowers, Brussels sprouts and all kinds of winter greens, doing the operation during a damp spell, if possible.

Keep the surface soil moving freely between rows of potatoes and earth up.

Train outdoor tomatoes and pinch out the numerous shoots which arise from the base of the leaf stalks.

Keep a sharp look-out for green fly and mildew on roses. For the former use an aphis brush, or spray with soft soap and water. For mildew sprinkle the affected foliage with flowers of sulphur.

Do not hesitate to remove a proportion of the smaller buds on the rose shoots; if this is done, those that are allowed to remain will develop much better.

Cut down the stalks of perennial plants when the flowers decay, and, in most cases, you will get a second crop of bloom.

Evergreen shrubs and hedges will now be making rampant growth, and these should be trimmed back. Shears do well for privet and small-leaved plants, but for laurels and aucubas secateurs should be employed, to avoid cutting the foliage.

Where the branches of fruit trees are within easy reach, thin out poor specimens of fruit, especially where there is any sign of overcrowding. In the case of fruit trees that have been newly planted, the thinning should be done somewhat drastically.

Keep a sharp look-out for weeds and have the hoe going constantly, both in the kitchen and flower garden. Watch gravel paths for the first signs of weed growth and, after a shower, uproot the plants while the gravel is moist.

A good deal of watering may have to be done, but to be effective this must be regular when once started. Instead of a mere sprinkling now and then, it is better to rely solely on the powers of the hoe to prevent evaporation. At this early part of the season it is only shallow-rooted plants, or those that have been recently removed, that will require water at all. Deep-rooted subjects are not likely to suffer from drought at the present time.

Flowers for Cutting.

A READER who asks for a few suitable flowers for cutting, to be raised from seed, will find the following selection useful:

PLANTING OUT SUMMER BEDDING PLANTS.

Calceolarias, schizanthus, nemesias, etc., can all be planted out now. Remove the crocks and slightly loosen the roots without disturbing the soil before planting.

columbine, especially the long-spurred varieties; giant thrift; Geum Mrs. Bradshaw; sweet rocket, fragrant; sweet william; and Orange King snapdragons. These can all be raised from seeds sown out of doors now.

Hints on Summer Bedding.

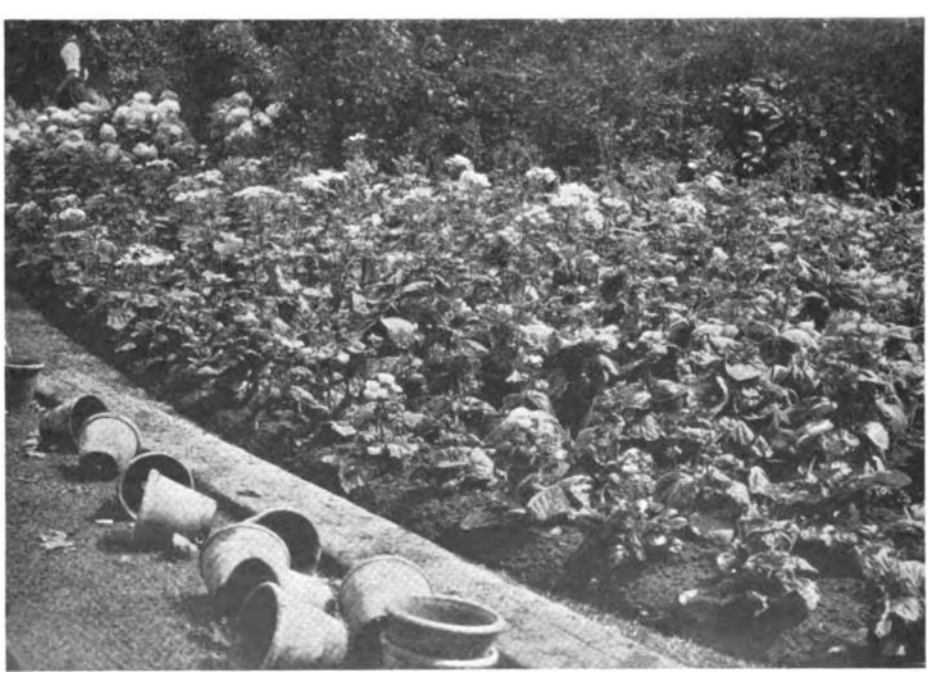
THE great variety of plants obtainable at this time of year suitable for planting out now affords the amateur an excellent opportunity to brighten up his or her garden for the summer and autumn. Preliminary to planting these, beds and borders should be cleaned and turned over with a digging fork, care being taken not to bring to the surface any manure which may have been dug in previously, and, if the soil is at all poor, a light dressing of one of the many fertilisers now obtainable or of bone meal may be lightly pricked in. Should the ground be at all dry, it is advisable to tread this over and level off with a rake, keeping the centre of the bed or the back of the border, as the case may be, higher than the front, and as it is desirable that the soil should be moist when planting takes place, the ground should be well soaked with water some time previously. Whether the plants you propose to plant are in boxes or in pots, these should also be watered some time beforehand so that they are neither bone dry nor sodden, and on no account should any of the plants be left lying about with their roots exposed for any length of time before being planted. Do not place plants out of pots in the ground without first removing the crocks and gently opening up the bottom of the plants, particularly if they are at all pot bound.

Before starting to plant, set the plants out in their positions, making sure that the outer ring or edging is completed before working inwards to the centre, and if due consideration is given to the size to which each plant will ultimately attain and sufficient space is allowed for this development and no more, the appearance of the plants when in flower will be much more pleasing than if these are badly spaced.

Much is written about colour schemes, but if you bear in mind that you are the person to be pleased, make as much use as possible of your particular favourite flowers, and stick to the quiet soft shades in preference to harsh, glaring colours, you will not go far wrong. Space does not permit enumeration of other than a few suitable plants for bedding, and the undermentioned are some taken at random from among the most easily grown.

Dwarf and Suitable for Carpeting and Edging.—Begonia semperflorens (pink, white and red flowered), Verbena venosa, Alyssum Little Dorrit, Phlox Drummondii, Dianthus chinensis, Tom Thumb antirrhinums, Verbena Miss Willmott and Cineraria maritima.

For Massing and General Use.—Pelargoniums, calceolarias, godetias, clarkias, salpglossis, antirrhinums, pentstemons, stocks (ten-week), coreopsis, China asters, Mignon dahlias, heliotropes, nicotiana, stock-flowered larkspurs, Aster Amellus types, zinnias, petunias, and violas and pansies.



WHEN PLANTING A BED IT IS ALWAYS ADVISABLE TO LAY OUT THE PLANTS FIRST.

The edging should be planted first and the remainder of the bed filled in later. As the edge of the lawn is apt to become worn by treading on it it is advisable to place a narrow plank of wood along the edge to keep it clean and tidy.

THE GREAT CHELSEA SHOW

WITH another Chelsea Show behind us, another notable milestone has passed in the annals of British gardening and in the history of the Royal Horticultural Society. This year the Show eclipsed the displays of the last few years and according to many was the most magnificent collection of gardens and flowers that has even been brought together at Chelsea. Certainly on this occasion it was more of a real flower show and less of a garden display, as on the whole the outside gardens were fewer in number, while the indoor exhibits had increased. The season seems to have suited the majority of exhibitors, as seldom, if ever, have the exhibits of individual flowers been finer. The Show continues to increase in size and this year a greater area has been devoted not so much to the exhibits themselves, but to providing better facilities for viewing the display. The number of exhibits has increased, while those of garden sundries have overflowed from sundries avenue on to the main lawn. In addition, considerable space is devoted to exhibits by artists, while the educational exhibits from various research stations were a particular feature which we hope the visitors to the Show noted and appreciated. Their Majesties made their usual detailed survey of the Show on the day prior to the opening and displayed considerable interest in many of the exhibits. There is little doubt that Chelsea maintains its position as the premier flower show of the world and this year's exhibition should do much to stimulate the love of gardening and flowers.

MODEL GARDEN LAY-OUTS.

What in previous years had been classed—often wrongly—as "formal gardens" were this year divided into two classes—formal gardens and others.

The exhibit of Messrs. Vernon Brothers might be taken to show a complete town or suburban garden designed for those to whom simplicity makes appeal. A simple semi-circular terraced pergola, walling of stone, pillars of plaster, formed a background to a circular pool with a splendid original bronze two-figure group. Box hedges framed the picture and narrow flower borders before them provided colour.

Messrs. Pulhams presented a square rose garden, on a large scale for Chelsea. One corner was devoted to a terrace-pergola carried out in coursed stone and roofing tile. A rather large and open dripping well below the terrace would, perhaps, have supplied sufficient water without two other small square pools set diamond fashion. Polyantha roses and anchusa did duty at this season for the hybrid teas and delphiniums of our July gardens.

The famous Crawley house of Cheal had a garden on straightforward lines, with the usual raised finishing terrace, backed, in this case, with a variety of evergreens and a kaleidoscopic mass of azaleas. In lieu of the usual dripping well there was a circular tank with a simple fountain, and the waterside planting was in character. For the rest, polyantha roses were freely employed.

Messrs. R. Neale and Sons had a complete suburban garden lay-out with a sunk garden as its main feature. This last would have been better if sunk less deeply, but the whole lay-out, and particularly the use of box edging with walling, was helpful to the seeker after ideas.

Messrs. Macdonald, the grass specialists, showed their splendid turf in an, for them, unusual setting, for a central cross-shaped pool and a bank of flowering shrubs were, this year, introduced. Apart from the quality of the turf, the feature of the garden was its perfect finish, which some exhibitors would do well to take to heart.

Of gardens not altogether formal is character, Messrs. Carters' was the most spectacular with its central skeleton temple on a stone platform and its twin "Niagaras" of water, such as one only sees at shows.

THE SEMI-FORMAL GARDEN LAID OUT BY MESSRS. CARTER'S.

THE SMALL TERRACED FORMAL GARDEN DESIGNED BY MESSRS. CHEALS'.

Fine and well arranged plantings of rhododendrons were a feature.

Messrs. Wallace of Tunbridge Wells used informal water and contoured turf for their country cottage garden, the only touch of formality being a neat stone-built summer-house and its surrounding semi-formal terrace.

Messrs. W. H. Gaze and Son broke fresh ground at Chelsea with a large, but, alas! almost rectangular, pool, a Japanese tea-house on piles and the usual plank approach across the water. The great drawback to these gardens in Britain is the gnats; a minor drawback to this one, that not all the plants were in character.

A trout-stream weir and an "antique" summer-house called attention to Messrs. Bakers' exhibit, which, among other features, had a hog-backed bridge in stone over the stream. Rather too much seemed to have been attempted in the space at disposal, and we noted that the bridge was turfed.

Mr. Ernest Dixon had quite a pleasing rock garden laid out on rather conventional moorland lines, but the tiny sunk garden he included with it tended to "cheapen" it and render it less effective.

Digitized by Google

The Horsecombe Quarries' exhibit showed a variety of stone walling and balustrading with vases, sundials, seats, tables and a dovecote, all in Horsecombe stone. Incidentally they accomplished a very nice little sunk garden.

A little sunk garden of some merit was shown by Messrs. A. Charlton and Sons. Small pieces of turf with a verge left to show above the surrounding paving looked "spotty" and restless, and we did not like the backs of the otherwise charming built-in stone seats. Messrs. Hodsons also had a tiny sunk garden, so tiny as almost to be a model.

Messrs. Cuthbert had a large informal exhibit with many good flowering shrubs, particularly azaleas, and a line of bush wistarias—very effective, but planted *in the turf!* Plants rather than lay-out seemed to be the object here.

A model bowling green and models of hard and grass tennis courts, all to the scale of 1 to 6, were shown by Messrs. Sutton and Sons in a very pleasing setting of greensward, paths and yews. The neutral-coloured hard court—a speciality of the firm—attracted favourable attention, and the quality of the turf was excellent.

Messrs. William Wood and Co. of Taplow set up a little paved garden, chiefly remarkable for its stepped rill in the Italian manner. More space is, however, necessary to carry out this idea effectively.

A SECTION OF MESSRS WHITELEGG'S ROCK GARDEN.
Awarded the Sherwood Cup for the best exhibit in the show.

OUTSIDE ROCK GARDENS.

The rock gardens at Chelsea challenge the impossible; for no art can quite anticipate the beauty that comes to a rock garden when, in three or four years, the plants have grown into congruity with the lines of the stone and reproduced for us something of the satisfying loveliness of "the standing hills, long to remain." Yet, every year, some, at least, of the gardens almost achieve the illusion, and we must give full credit to the patient artistry that aims at, and so nearly reaches, the impossible. Without grudging a little licence to the means employed, we need not object too strongly that the artificially dwarfed Japanese trees are not very suitable subjects for an English rock garden, for they give us, here at Chelsea, the effect that we can get—in time—with the naturally dwarf conifers when they have reached maturity.

The alpine illusion was created most perfectly by Messrs. Whitelegg, whose design was one of the best seen at Chelsea for many years. It reproduced, on the grand scale, a mountain path crossing a torrent and winding up over the hillside. The large rocks of beautifully weathered limestone, some of them mellowed by a golden patina of lichen, were so well placed that they were of sufficient beauty in themselves and in one place they were allowed to assert themselves with rare artistry, through a carpet of rough grass and lady's-mantle. Colour was given chiefly by a great drift of soft pink phlox streaming down among the grey boulders and a scarlet fleck of Verbena chamædryoides was so telling on the top of a grey pinnacle that the presence of this impertinent stranger from the river banks of South America could be easily condoned as a pleasant surprise in a typically alpine landscape. A little moraine in the foreground made a home for some choice small plants, Silene Hookeri, Ourisia coccinea and some lewisias.

Messrs. Hodsons of Nottingham made a garden next door of heavily stratified limestone in terraces, with a stream whose windings were skilfully emphasised by dwarf conifers, in a way that recalled their use by the Japanese gardeners. In spite of the vivid pinks and yellows, the effect was a little monotonous; but the design in itself was good and geologically faithful, and in a few years it would produce, with careful planting, a very quiet and restful garden not altogether out of keeping with the English landscape.

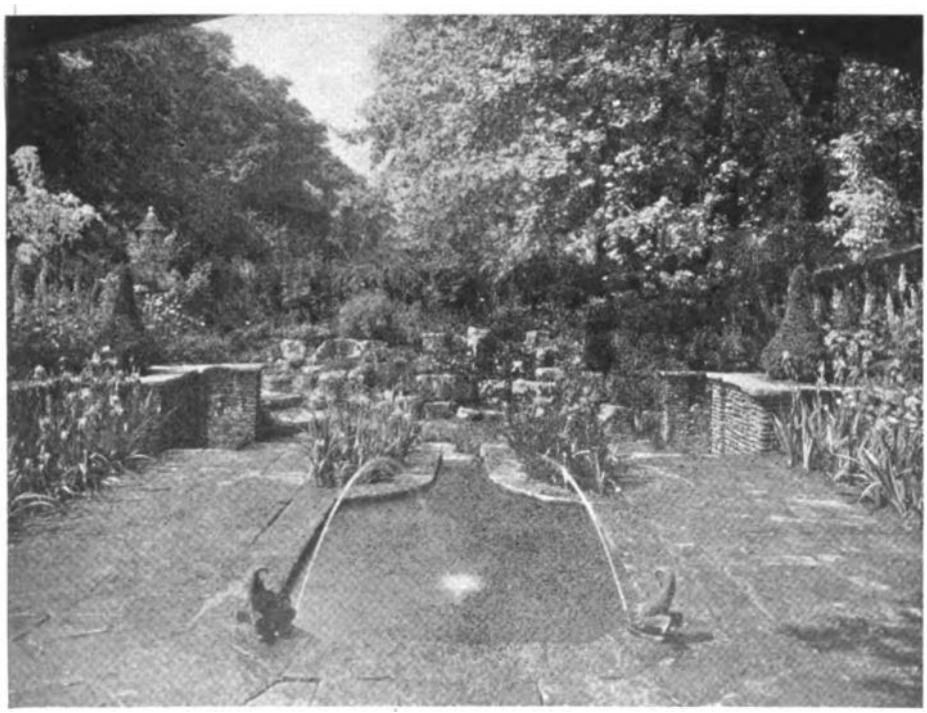
Messrs. W. H. Rogers made an unambitious mound dotted with the small conifers for which the firm is famous, and drifts of pinks and pansies and showing off a good group of Aquilegia glandulosa.

Messrs. Gavin Jones reproduced in a small compass a piece of typical and very beautiful alpine scenery in a carefully balanced design centring round a tall, sheer-walled bluff, with a stream tumbling out of a rocky gorge at one side of it into a deep, quiet pool. The planting was admirably restrained, mostly in cool creamy white and soft pink and grey, lit up by one flaming clump of the soldier scarlet Tulipa Sprengeri.

Messrs. Clarence Elliott had a small conical hill jewelled with dwarf plants, a gay and mildly fantastic paradisal mountain, the lower slopes iridescent with wahlenbergias, alpine pinks and potentillas; the superb, luminous blue Meconopsis betonicifolia and that rare annual, M. heterophylla, a curiously coloured (terra-cotta scarlet) American. It was essentially a rock garden laid out on business lines.

Under an oak tree, at the opposite end of the rock gardens, Mr. Clarence Elliott showed what could be done in sink gardening, of which he is the inventor.

Messrs. Herbert Brook made a quiet garden whose restful design was enhanced by the ancient mossing of the weathered boulders. A small stream trickled down a green cliff in the background and wandered along a



THE ATTRACTIVE PAVED GARDEN DESIGNED BY MESSRS. WOOD.

Digitized by Google

grey beach in the foreground, studded with the pale blue Myosotis rupicola, shading back to a deep blue clump of gentianella and the wonderful sky blue of Meconopsis Prattii. Altogether a very satisfying and charming little garden.

Messrs. Pulham led their stream along the face of a grey cliff, fronted by an open stretch of turf, a good, practical design that deserved more thoughtful planting than the rather conventional azaleas and Lithospermum Heavenly Blue.

Messrs. Cutbush made no attempt to evoke the Alps and the suggestion of browsing goats round the corner, but made a slightly futuristic garden of angular bathstone with a conflagration of azaleas bursting over a fern covered stream and the curious metallic greens of Allium karataviense and funkias against reddish yellow rocks. A quite legitimate type of rock garden of a special kind.

TULIPS.

Tulip lovers will be sorry that the late date of Chelsea prevented the majority of bulb growers from exhibiting. At the same time, credit is reflected upon the few firms who showed these flowers, in that the exhibits were of generally high standard of quality, notwithstanding the late date and trying season.

Messrs. R. H. Bath, Limited, of Wisbech, put up a good show of about six dozen varieties in which we noticed Caledonia (orange scarlet), Triton (rose pink), W. T. Ware (deep yellow) and Princess Juliana (scarlet) in particularly good form.

Messrs. Dobbies of Edinburgh have the advantage of growing their Chelsea exhibit in Scotland, where the season is later; but this year snow and frost have played havoc with Scotch flowers. Notwithstanding these difficulties, there was little to indicate even to the practised eye that the season has provided difficulties of any sort. The following varieties of merit were noted: Vesta (white), scarcely fully opened; City of Haarlem, an excellent form; King George, a flower very near to Chant de Cygne; Harry Veitch, wine red; and Louis de la Valliere.

Messrs. Barr and Sons made a very bold and comprehensive display of flowers of first-rate quality. Noticeable among many others were bold groups of Farncombe Sanders, Zomerschoon Superba (a rich chocolate), Panorama and Prince of Orange—a variety which is deservedly becoming more popular every year.

Mr. H. G. Longford of Abingdon put up a 20ft. stand decorated with tulips and iris. Varieties we noticed in very good form were Prince of Orange, Zany, Vesta, and the ever popular Bouton d'Or.

Messrs. Miller of Wisbech put up a group which included Amber, Inglescombe Yellow and Triton in good form.

Tulips were also shown by Messrs. Bronwylfa Fruit Farm of St. Asaph and Messrs. Daniels of Norwich.

ROSES.

There were eight exhibits of pot-grown roses, and it was evident, from the predominance of the polyantha and rambler types, that the season was rather far advanced for the hybrid teas. Nevertheless, the latter class was fairly well represented, and, considering the warm atmosphere, the flowers stood the ordeal better than might have been expected. There was considerable diversity in the treatment of the exhibits, and while the larger groupings afforded greater opportunities in the direction of artistic effort, all of them reached a high level of decorative excellence. Irish and Scotch growers were conspicuous by their absence, but they seldom put in an appearance at the London shows

A PORTION OF MESSRS. BUNYARDS' EXCELLENT EXHIBIT OF IRISES.

THE BOLD DISPLAY OF TULIPS ARRANGED BY MESSRS. BARRS.

MESSRS. B. R. CANTS' ATTRACTIVE EXHIBIT OF ROSES.

Digitized by Google

before the exhibition of the National Rose Society.

New roses formed the chief attraction of the group staged by Messrs. Ben. R. Cant, Colchester. Hilda is a pretty variety of the Betty Uprichard colour type, but the shades of pink on the outer and inner sides of the petals are quite distinct from the Irish production. The flowers are large and well shaped, being full and pointed in the bud stage, and the foliage provides a fine setting. Joan Cant is, perhaps, the outstanding rose novelty in the Show. It is an exact duplicate of the popular single H.T. Isobel, but in a semi-double form. Like its prototype, it comes into bloom very early in the season, continues flowering until late in the autumn, and is beautiful at every stage of its career. The habit is the same and the decorative foliage of the Irish rose is maintained in the new form, Cecil, a single rose of rich yellow colour, has also a free-flowering character from early summer on to November in normal seasons.

Messrs. Chaplin Brothers of Waltham Cross were successful in staging a representative group of polyantha, Wichuraiana and hybrid tea roses of uniformly good quality. The finest blooms in the latter class were Admiration, Shot Silk, Betty Hulton, John Harvey, Souvenir de Claudius Pernet, Bessie Chaplin and Pearl White.

One of the corners at the rock gardens end of No. 2 Tent was occupied by an extensive display of Polyantha roses from the nursery of Messrs. William Cutbush and Son, Barnet. It made a pretty-coloured picture. The favourite dwarf forms occupied the ground space and were surmounted by graceful standards and weepers. Prominence was given to a perpetual-flowering seedling of the dwarf polyantha type obtained by crossing George Sedger and William Allen Richardson, and the influence of the latter is reflected in the new shade of colour. Other outstanding varieties were Kersbergen, a lovely shade of crimson, Mary Casant and Frank Leddy.

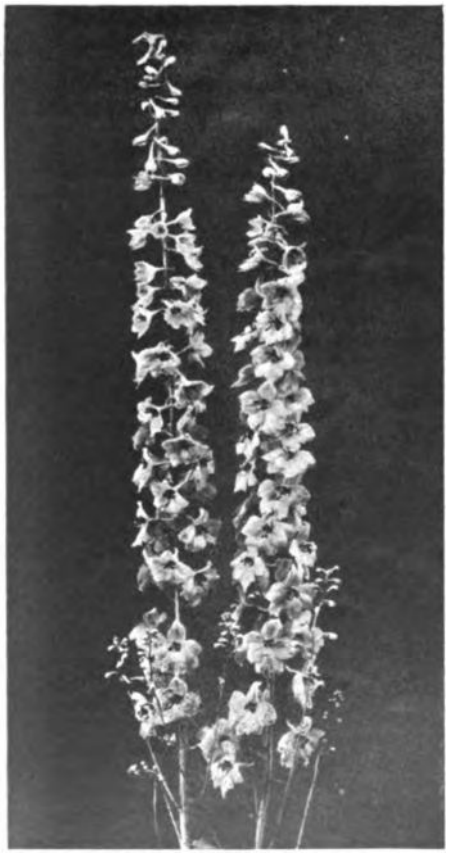
Hybrid tea blooms, exquisite in form and charming in colour, were to be found in the group provided by Messrs. E. Paul and Co., Cheshunt. The older favourites were represented by Ophelia, Mrs. Aaron Ward, Mme. Abel Chatenay and Mrs. Sharman Crawford; the more modern examples by Los Angeles, America and Mrs. Henry Morse; while Lady Sylvia, a highly coloured sport from Mme. Butterfly, was typical of the novelties.

Lady Sylvia was also prominent in the exhibit of Mr. George Prince, Oxford, who staged Locarno and Golden Salmon (polyantha) in a collection that was neither lacking in variety nor quality of bloom.

Dainty Bess never looked more fascinating than it did in the goodly company of new and popular roses grown by Mr. Elisha J. Hicks, Twyford. Angele Pernet was also shown in grand condition, and a trio of novelties, consisting of F. M. Vokes (deep cream, which has a tendency to whiten with age), Mary Hicks (a new crimson climber) and Pride of Hurst (salmon pink) all contributed to the gaiety of the colour scheme.

Mr. C. H. Pemberton, Romford, was responsible for a small and interesting collection which embraced many other polyantha types, including examples of Banksia Chatilion, Echo and Lord Reading.

Although the roses at the Braiswick Gardens, Colchester, were at their best ten days ago, Messrs. Frank Cant and Co. managed to put up a first-class exhibit that embodied rambler, polyantha and hybrid tea types in variety. The firm's outstanding blooms were Captain Harvey Cant, Mrs. Harvey Cant, Lord Lambourne, Mabel Morse, Salmon Queen, Locarno and Golden Salmon.



DELPHINIUM COQUETTE OF THE WREXHAM STRAIN, SHOWN BY MESSRS. HEWITTS.

IRISES.

Among several most interesting collections, the finest staged was that by Messrs. Bunyard and Co., whose group was in all probability the best and most pleasing ever staged at this spring show. The connoisseur of irises was attracted by several fine new seedlings, but the very cream of both newer and standard varieties were also in evidence. Among the seedlings the most noteworthy was Castor, a plant of moderate growth and bearing a flower of no more than medium size, but of splendid form and beautifully poised, the standard an unusual tone of bronze, the falls browner, reticulated pale violet and stippled with ivory; the neat beard golden. Another very striking seedling had the recurving falls and general shape of Iris Susiana. In colouring this remarkable flower seems to imitate Spanish mahogany, but the standard is buff, lined bronze. The "pink" shades were well represented by such sorts as Susan Bliss, Mrs. Marian Cran (perhaps the best so far of its colour), Aphrodite and the still useful Queen of May. The still rare René Denis, "pink" with bronze toning is, perhaps, overrated. Other good ones noted here—some of them more or less standard sorts—were Mme. Schwartz (palest lavender), Ambassadeur, Lent A. Williamson, and Perseus (a new one this and a great improvement upon Yeoman).

The firm of Amos Perry always has something good and new in irises, and the comparatively small quantity grouped among his hardy ferns were of the best. The giant Mestor, an almost self variety of purplish violet colouring; Duke of York, a rather rosy pallida; Mary Gibson, a study in bronze and old rose; Mrs. H. F. Bowles, gaily clad in old gold and red tones; Ruby Perry, soft rosy violet; Lady Charles Allom, real violet; Lord Lambourne, whose standard is rosy fawn, bronze shaded and falls madder crimson much reticulated with white at the

MRS. FOSTER CUNLIFFE, A NOVELTY RAISED BY MESSRS. BLACKMORE AND LANGDON.

Note the difference in habit between the two types.

haft; and Crimson Glow, rosy crimson, include some of the best of the bearded novelties seen only on this stand, which also included Mrs. Marion Cran and Lent A. Williamson. Besides the bearded sorts, this group contained a charming collection of the Californian species and their hybrids.

The Orpington Nurseries had a large group comprising fine clumps of the newest and newer varieties. The following were particularly noted here: Cygnet, ivory and amber, with reticulations of pinkish bronze; Evadne, in shades of rosy terra-cotta; Anna Farr, a very pretty plicata; Argynnis, bronzy crimson and orange dun—a fine flower; Ophelia, of coppery tone with rosy lavender on the centre of the falls and golden beard (most attractive); and Istria, after neutral colouring of Florentina, but of better form and, like Florentina, fragrant.

Mrs. W. R. Dykes showed some of the beautiful varieties raised by the late Mr. W. R. Dykes. The following really good ones were noted: Venetia, violet with a good orange beard; Amber, surely one of the very best yellows; Moonlight, sulphur overlaid with bronzy lavender; Sapphire, well named, dwarf and free; Lustre, a fine red violet; albicans virginale, a beautiful white of admirable form and almost unmarked; and that really good deep "pink," Aphrodite.

Messrs. John Waterer, Sons and Crisp, Limited, featured in a mixed plant group such good bearded sorts as Ambassadeur, Shekinah, Souv. de Mme. Gaudichau, Fürstin Longay (a good "deep rose"), Lord of June, Dalila (bronzy red and amber) and two giants in Prospero and Magnifica.

Messrs. Barr and Sons had the rather dwarf but very pleasing Toolen's Yellow (buffish citron), the terra-cotta Mount Penn, the brown-toned Prosper Laugier and

Digitized by Google

Wyndham (almost clear rose with darker reticulations).

Messrs. Lowe and Gibson used choice bearded irises as foils to their beautiful border carnations. Thus menially employed we noted the showy Queen of the Dale, Corida (one of the best and freest lavenders for the garden), Troost (standard purplish rose, falls similar, but veined violet), Afterglow, Shekinah (a tall and stately yellow), Shalimar, Mount Penn, Tom-Tit (a miniature violet sort) and Montezuma (old gold).

Messrs. Maurice Prichard and Co. had Lent A. Williamson, odontissima Ewbank, Souv. de Mme, Gaudichau, the mid-violet Gold Crest and the bronze-toned crimson Mrs. Cowley.

A corner of Messrs. R. Wallace and Co.'s rhododendron and lily garden was devoted to irises, with Alcazar again in evidence, as well as Franklin Beynon, an extra good rose, and other well known sorts.

Spanish, and particularly the newer Dutch irises, were shown by many firms, including Messrs. Carters, Mr. A. Dawkins and Messrs. Toogood and Son.

A PORTION OF MESSRS. WATERERS' FINE EXHIBIT OF HERBACEOUS PLANTS.

SHRUBS.

After the cold weather of late April, it was hardly fair to expect the same wealth of flower on flowering trees and shrubs as in past years: in fact, it is surprising that the shrub exhibits were as good as they proved to be. First in point of excellence came the rhododendrons. Messrs. Wallace staged a really fine group of the more modern hardy hybrids, very well grown and full of flower. Probably pride of place would go to Britannia, a new Dutch hybrid of great substance and a rich scarlet with no hint of blue in the colour.

Messrs. Waterers' exhibit consisted of magnificent plants of their well known hybrids, such as Sappho, Pink Pearl and Mother o' Pearl. Among the novelties were a new hybrid (Rh. discolor × C. S. Sargent), a good rose and late in flowering from its discolor parentage, which is a late-flowering Chinese species. We were also glad to see several plants of Rh. chionoides, an old hybrid almost lost to cultivation and a very late flowering white. It suggests Rh. maximum × Rh. caucasicum album as its parents. Messrs. M. Koster also staged their well known hardy hybrids, such as Norah, a good truss of pale pink; and Miss Noreen Beamish, a fine rose shade. The Executors of Mr. Slocock also specialised in good hybrids, among them being the fine old yellow Broughtoni aureum and their own excellent yellow hybrid Goldsworth Yellow, still difficult to beat. They also showed Lord Roberts, one of the darkest of all reds with a black blotch.

Azaleas were staged by Messrs. Cuthbert and Messrs. L. J. Endtz. Among older favourites on the stand of the former were fine plants of two mollis × sinensis hybrids—Southgate, a good orange scarlet; and Boy, a pale yellow tipped with carmine. Probably the most notable plant on Messrs. Endtz' stand was Dante Gabrielle Rossetti, a curious shade of white with a cool greenish tinge. Among the dwarfed Japanese trees the Yokohama Nurseries showed some excellent pale shades of the free-flowering Kurume azaleas, among them a charming shell pink, named Azuma-Kagami, a very superior plant.

Messrs. Watson's of Kilkenny, Ireland, were again to the fore with their wide range of attractive flowering brooms. Among the best was the new novelty Lord Lambourne, a sport from C. Andreanus, and of somewhat paler colouring. It should prove popular.

Among the general collections of trees and shrubs Messrs. Hillier's exhibit was notable for variety. Everyone admired the Japanese forms of Prunus serrulata, among them a form of rosea called Shidara-Sakura, a good pendulous double. We were also pleased to see the old-fashioned double bird cherry, P. Avium fl. pl. The wistarias were also excellent. Most interesting were the pans of young plants, such as Olearia insignis and Osmanthus armatus, both pictures of good health.

Messrs. Cheal staged rhododendrons, azaleas and general flowering shrubs, among the last being Viburnum macrocephalum, that magnificent sterile white, and the little double white Philadelphus, Gloire de Neige. Mr. Notcutt staged a representative collection of his famous cytisus along with flowering shrubs. We noted among them C. sessifolius, a good yellow with tiny foliage; and C. scoparius Dragon Fly, yellow and deep crimson, a fine combination of rich colour. Messrs. Gill showed fine vases of shrubs, many of them on the tender side. In the centre was a wonderful vase of Embothrium coccineum, flanked by another equally large of Tricuspidaria lanceolata. On this stand was a very dark form of weigela called Eva Rathke. Mr. Reuthe had a fine exhibit of rare shrubs and rhododendrons.

Messrs. Whitelegg had a well staged exhibit of azaleas and rhododendrons overhung by white wistaria, a very fine form that should be more often seen in gardens.

MESSRS. WEBBS' COMPREHENSIVE DISPLAY OF GREENHOUSE FLOWERS.

LILIES.

This was not an extensive class, but what was lacking in numbers was made up by the quality and variety of Messrs. R. Wallace and Co.'s collection. It was a group apart from any other in the section, and was noteworthy for the beauty and distinctive forms of the flowers. Examples of Thunbergianum and umbellatum contributed to the excellence of the display, of which the following were prominent: Regale, Brownii, Orange Queen, Davidii, Backhouse hybrids, Golden Fleece, Martagon album, longiflorum giganteu and japonicum.

A few exhibitors included liliums in their general exhibit, and in this connection Messrs. Bunyard were represented by candidum and Regale, and Messrs. Lowe and Gibson by small groups of Hansoni and Regale.

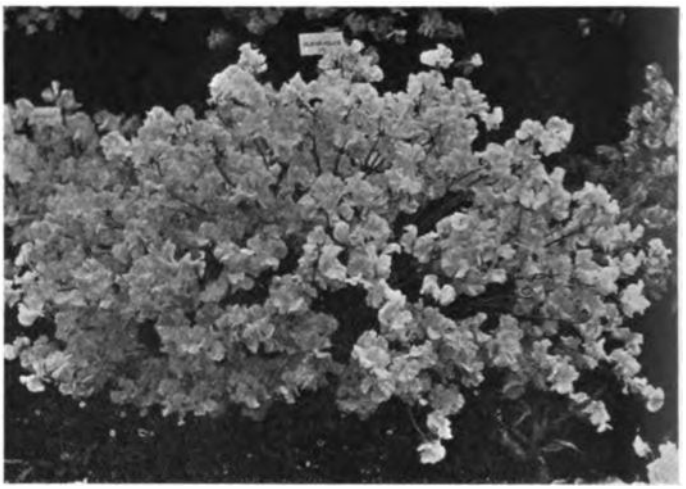
A MOUND OF SALPIGLOSSIS IN MESSRS. SUTTONS' SPLENDID DISPLAY.



A BOWL OF SWEET PEA GLENEAGLES IN MESSRS. DOBBIE'S VERY FINE EXHIBIT.

GREENHOUSE PLANTS.

In the first of the two very large tents Messrs. Sutton and Sons filled four spaces with the most varied and, undoubtedly, best collection of salpiglossis that has ever been seen. Their superb plants were a revelation to many amateurs who have achieved only moderate success with these lovely plants. The salpiglossis is not a plant for the happy-go-lucky gardener who is content to scatter seeds in his borders and hope for good results. The salpiglossis demands good attention and is well worthy of it. Many gardeners are well aware that really good results with salpiglossis can only be obtained by sowing the seeds in the autumn and attending to the plants during the winter. But Messrs. Sutton and Sons have gone rather farther than this, for we understand that the seeds were sown last August and the plants wintered in as cool conditions as possible, always provided there was no possibility of injury by frosts.

The results amply repaid the care and attention bestowed on the plants, and few who attended the Chelsea Show will forget the feast of floral beauty these handsome plants provided. There were thirty-five distinct varieties grouped in generous quantities, and the colours of all were most entrancing. Probably many, at first, most admired the rich beauty of the variety named Velvet Red, and its intense velvety red colouring is, indeed, worthy of admiration. But each of the many distinct varieties possessed great charm of colour combination and of delicate markings on its flowers.

An equally large space placed at the disposal of Messrs. Carter and Co. contained much floral beauty of another character. They had three large groups of greenhouse plants linked together by arches of beautiful sweet peas. In these groups there were masses of clarkias, schizanthus, nemesias, tall rehmannias with large foxglove-like flowers of lovely pink colouring, rose-coloured petunias, large-flowered calceolarias, profusely flowered plants of Cineraria stellata varieties, gloxinias of a splendid strain bearing many large flowers of rich velvety colours, tuberous-rooted begonias of enviable quality, bulbous-rooted irises and other plants all of value for the spring and early summer decoration of the greenhouse. These most fascinating and artistically arranged groups were enclosed by turf edgings of rich green grass, among which not a single weed could be seen, and a row of a very desirable ageratum which bears graceful sprays of a beautiful shade of mauve gave an attractive finish to the exhibit

Greenhouse plants which also illustrated first-rate strains and expert culture were well grouped by Messrs. Edward Webb and Sons in another part of the first tent. They had pillar-like plants of a salmon clarkia bearing hundreds of beautiful flowers. Salpiglossis and schizanthus and Cineraria stellata varieties were also present in large floriferous specimens. Towards the front there were plants of Primula obconica gigantea which impressed one by their vigour and the unusual size of the blooms. Nemesias of delightful colouring and the quaint beauty of the many sturdy plants of their dwarf cactus cineraria also compelled admiration. This firm's new giant hybrid schizanthus in all shades were particularly fine.

Mrs. Denny of Horwood House, Bucks, and Mrs. Sheppee of Holly Springs, Bracknell, both sent exceedingly good collections of the graceful Calceolaria integrifolia. The latter also had an admirable selection of hybrids bearing countless little flowers of great beauty, while Mrs. Denny associated statice profusely with her calceolarias in a pleasing way.

A pretty little group was arranged by the students from Studley College. In the centre there was a batch of an admirable pink-coloured Brompton stock and also an unusually brightly coloured strain of Rehmannia angulata.

The beauty and charm of fuchsias when well grown and in small pots was well illustrated by the Castle Nurseries, who had admirable plants of The Doctor, Achievement, Emile Zola, Mauve Beauty, Fascination and other good sorts; while Mr. R. J. Case and Mr. W. A. R. Clifton showed fine trusses of zonal pelargoniums.

Several well grown plants of the bottle brush tree in the group of Messrs. Stuart Low and Co. attracted a deal of attention. They showed to good effect, next to the brilliant red whorls of these flowers, good bushes of leptospermums, hippeastrums and Humea elegans.

A very handsome collection of hippeastrums from Lady

MESSRS. OLIVER AND HUNTER'S EXHIBIT OF MANY OF THE NEW CHINESE PRIMULAS SUITABLE FOR THE ROCK GARDEN.

Digitized by Google

Aberconway's garden at Bodnant, North Wales, wasmuch admired. All the plants were raised at Bodnant, and they represented many delightful colours.

The double-flowered tuberous-rooted begonia seems to be the despair of many amateur gardeners, but these showy plants cannot possess many difficulties for Messrs. Blackmore and Langdon, who set up many really magnificent plants. Their flowers are always of immense size, but of perfect shape and of every possible shade of colour. Of the many distinct varieties we selected the following as being representative: Peace (cream coloured), Hilda Langdon (shell pink), Brian Langdon (deep rose pink), Mrs. J. Davidson (yellow), Mrs. Peter Blair (white), Lord Lambourne (rich orange), Grand Monarch (crimson) and Betty Hampton (rosy salmon). They suspended over these superb plants baskets of such graceful pendulous varieties as Mrs. Bilkey (orange), Coralline (pale coral), Lena (red), and Mollie (pale blush).

On entering the first tent from the Hospital end the visitor might well have thought tha hydrangeas were the principal feature of the Show, for there were two immense collections of these handsome flowering plants. Farther down the tent there was another large group, and a number of exhibitors associated hydrangeas with various other plants. It was rather fortunate that the three large exhibitors of hydrangeas had adopted quite different styles of arrangement, so that there could be no temptation to form comparisons. Baron Bruno Schröder sent a large collection from The Dell, Egham, and his fine plants were arranged in a low bank relieved by stone vases containing selected plants. At the same end of the tent Mr. H. J. Jones had an extensive group, which was set up very attractively. In the centre he had a mass of the rich pink variety Parzival, and at each of the four corners he placed groups of his admirable seedlings. Many of these are excellent both in habit and in colour of the flowers. The trusses are large and well formed. Some of the heads are twelve inches across. Although he has staged many fine collections of these flowers at previous Chelsea's he excelled himself on this occasion.

In another part of the tent Mr. Philip Ladds exhibited a large number of hydrangeas of the best type grown for the market. These were arranged in an imposing group by Mr. H. Jolis, who was also responsible for the handsome collective displays the British Florists' Federation made recently at the Royal Horticultural Society's Hall in Vincent Square. The general idea was a series of ornamental baskets filled with distinct varieties and placed at different levels. In the centre there was a magnificent basket of Parzival. Smaller, but still large baskets, contained fine plants of Mme. Mouliere (a large truss of white flowers which have a violet eye), Mme. A. Riverain (rich blue) and Peer Gynt (a beautiful shade of pink such as is also seen in some bedding geraniums. Other desirable varieties in these handsome displays of hydrangeas were Heiderosee (a very large pink truss), Blue Prince (of hazy blueness on a solid pink ground), Thos. Stevenson (an immense truss of rich pink) and Le Cygne (one of the best whites).

SWEET PEAS.

Probably no other floral subject contributed more to the marvellous colour picture than the exhibits of sweet peas. All the leading raisers were represented and the artistic groupings marked a decided advance on those of previous years. Several novelties of distinctive merit were staged for the first time, and were greatly admired for their beauty of colouring, size and form.

Messrs. Dobbie and Co., Edinburgh, exhibited a collection which for size and variety excelled all previous efforts at Chelsea. It consisted of 60 modern examples, and 11,500 spikes, most of them carrying four blooms, were brought into the picture. Prominence was given to six new introductions, five of which are being distributed in the coming autumn. Hero, a deep rosy cerise flower, is a lovely colour with size and substance to its credit. Sunkist is a cream ground Youth that is much more pleasing in shade than the American pea and a great improvement on Jean Ireland; Prince of Orange, a richer and deeper Royal Sovereign, possesses all the good qualities of an exhibition and garden pea, and is arresting in the richness and depth of colour as well as size of bloom; Flamingo, orange-scarlet, received an award at last year's Scottish trials, where it distinguished itself out of doors; and Gleneagles, the new lavender, provided a lovely basket. But the gem of the collection was Pinkie, which we expect will take pride of place in its colour class. It might be described as a pink self, richer and deeper than Hebe. The flowers are immense in size and beautifully waved, the stems are long and the individual blooms well placed, and the general effect suggests a valuable acquisition to the class of sweet peas that are suitable alike for indoor and garden decoration. Another beautiful thing appeared as a sport from Mary Rose. It is a refined flower of a charming salmon pink colour. The King and Queen spent a considerable time inspecting this exhibit, and Her Majesty expressed her appreciation of the new varieties to Mr. Cuthbertson.

Mr. Robert Bolton's stand was also attractive, as the varieties were of uniform excellence and included several first-class novelties. Of these Mrs. A. Searles was outstanding. This salmon cerise, which received awards from the English and Scottish Sweet Pea Societies last year, was raised by Mr. Damerun, and was bought by Mr. Bolton at the largest price ever paid for a seedling. Jessie is a grand pink sort, and Susan belongs to the Picture type and has a resemblance to Mrs. Hitchcock. There was also a seedling of suffused pink on a cream ground which did not appeal to me, as it seemed to lack distinction of colour, and one of the best peas on the stand was the old lavender R. F. Felton, which, unlike many of the older varieties, does not degenerate with age when a good strain is grown.

Messrs. Carters' exhibit contained twenty choice varieties well grown and effectively staged. The firm's novelties were Mrs. A. Standford (light pink), Enid and Raynor Park (lavender).

The most was made of a 36ft. stand by Messrs. Alexander Dickson and Sons, Belfast. Their new introductions were tastefully arranged in baskets, and consisted of Corona (carmine rose), Boy Blue and a seedling of an orange crimson colour that was conspicuous among a representative group of up-to-date varieties.

A quartet of A 1 novelties were exhibited by Mr. J. Stevenson. Nina, a clear rose bloom, rather deeper than Magnet; Glorious is an improved Charming and deeper in colour than Coralline; Marjory, carmine; and Freda, blush pink on white ground.

CARNATION MRS. A. J. COBB, STAGED BY MR. A. F. DUTTON.

CARNATIONS.

The ever-increasing popularity of the carnation was clearly evidenced by the excellent exhibits staged by the leading raisers of this flower.

Messrs. Engelmann had a particularly imposing group in the centre of one of the tents. It contained many hundreds of bloom among which were the best of these modern perpetual carnations. Circe (heliotrope with cerise stripes), Lady Hindlip (white, pencilled red) and Dorcas (rich crimson) were all in good form. Sunny, with its shaded orange blooms, was one of this firm's novelties. Large vases of the dark-hued Nigger and the vivid Red Laddie made bright patches of colour.

The exhibit of Messrs. Allwood Brothers was not only imposing but interesting as well, for it contained perpetual carnations, border carnations, perpetual border carnations, this firm's famous Allwoodii pinks and also a new race of pinks which were being shown for the first time. The well known border carnations, such as Viceroy, Salmon Clove and Orangeman were included. Bryan, Peggy and Harold, three of the best of the Allwoodii pinks, were also on show and Pat, a cerise pink, novelty of the latter type, was most attractive

Digitized by Google

in colouring. The new race of pinks (Allwoodii alpinus), which has been raised by crossing Allwoodii with Dianthus alpinus, Dianthus deltoides, etc., is adapted for growing in rockeries, dry walls, etc., and owing to its perpetual-flowering habit this race of pink should prove a valuable addition to our gardens. Among the perpetual carnations Velvet was one of their most recent novelties.

A large group of perpetual carnations containing all the leading varieties was wall staged by Messrs. Stuart Low and Co. In a prominent position in the centre was a large basket of excellent blooms of Sir Philip Sassoon. This variety with deep velvety crimson blooms is one of the most fragrant of all carnations. Ruby Glow, another variety of rich colouring, also possessed a sweet scent. Sybil, one of their 1927 novelties, was on show. Red Laddie, Eileen Low, Mrs. Hamilton Fellows, Lord Lambourne and Lady Iverforth were all in good form.

Messrs. Keith Luxford's perpetual carnation exhibit included a number of old favourites, the majority of which were well known market varieties.

Mrs. A. J. Cobb, the bright crimson carnation which recently won the *Daily Mail* Cup for the most fragrant carnation was exhibited by its raiser, Mr. A. F. Dutton.

Messrs. Lowe and Gibson, whose fame as border carnation specialists is becoming widely known, staged a group which consisted mainly of pot-grown specimens of these hardy carnations. Some of the very finest varieties were included, and all the plants were strong, vigorous and healthy. Myrtle Pettigrew (old rose with scarlet bands), Mrs. E. Charrington (a white ground fancy) and Skirmisher (a yellow ground fancy) were particularly good in shape.

A collection containing many different varieties of the Douglas border clove carnations was exhibited by Mr. James Douglas, whose name has been connected for many years with border carnations. Some of the best of the Bookham varieties were on show, such as Bookham Flame and Bookham Belle. Flamingo, a striking orange-scarlet variety; Lieut. Shackleton, a cream ground suffused rosy pink; Princess Mary, a large apricot self; and Royal Clove, carmine-salmon, were well grown specimens.

Mr. Herbert had several attractive new varieties of his fine strain of pinks as well as some of the best of his older kinds. Novelty, a dark rose, and Princess Elizabeth, a soft rosy carmine, were two of the most outstanding. An attractive border pink called White Ladies, which is not only very fragrant but floriferous as well, was shown by Mr. Isaac House. Carnations were also exhibited by Mr. J. C. Beck.

ALPINES, INDOORS.

There were more exhibitors of alpine plants than ever before and none of the stands was dull or negligible.

Mr. F. G. Wood of Ashtead made a miniature rock pool bordered with brilliant mimulus hybrids and overhung with dwarf conifers. Alongside were the tiny Iris locustris; Dianthus callizonus earning its name for its fair girdle of speckled crimson; the softly purple Linaria origanifolia, the uncommon dwarf pink evening primrose Œnothera mexicana rosea and a fine pan of Rosa Rouletti.

Mr. W. E. Th. Ingwersen showed a collection of choice varieties, including Helichrysum bracteatum, a new everlasting from New Zealand, with large egg-shaped flowers of golden bronze, which is, fortunately, quite hardy; Potentilla Warrensii, a tiny plant with large yellow flowers; Trollius europæus albidus in creamy white; Halipterum althemioides, another new plant from the Antipodes carrying pure white everlasting flowers on slender stems; a good form of our rare native Viola lutea, which is much too seldom seen in rock gardens, and a remarkably beautiful series of Ramondia seedlings.

Messrs. Waterer showed the brownish crimson broom, Dorothy Walpole; Ononis rotundifolia, which looks like a tiny rose bush and produces bunches of pink pea flowers, a charming little plant for a dry wall; good forms of Primula japonica and Globularia incanescens.

Messrs. Wood and Son of Taplow, new exhibitors in this section, brought a very noteworthy collection, containing many new and rare plants, including Dianthus Fosteri, a tiny hybrid pink of intensely vivid magenta with a dull black eye and bronze foliage and a fine pure pink form of Primula farinosa.

Messrs. Clarence Elliott, Limited, showed, on a mossy rock slope, Oxalis enneaphylla and the form rosea, with its surprisingly large cups, deeply flushed with clear pink; the very rare native Potentilla alba, a minute shrublet with relatively large white flowers, and a fine clump of the lately reintroduced Gentiana pyrenaica.

Messrs. Hodsons of Nottingham showed that rare old pink Emile Paré, a perfectly formed jewel in creamy pink; Donizetti, another old border pink, standing alone in its peculiar colouring of dull crimson, with a darker eye and many good, purely alpine plants.

Messrs. Oliver and Hunter, specialists in rare primulas, showed P. flexilipes with long slender stems and bunches of pale sulphur yellow flowers swinging on delicate foot stalks; P. microdonta, another pale yellow, but tall, sturdy and statuesque; P. prionotes, a very strangely coloured flower, dusky purple without and painted inside with yellow farina; Farrer's form of Saxifraga primuloides, a fairy London Pride and that admirable shrub, Andromeda rosmarinifolia.

Messrs. Tucker showed large, healthy plants of Androsace pyrenaica, Smilacina racemosa, a rare plant with ample glossy green leaves and plumes of creamy flowers; the little vivid blue Mertensia echioides and many other good things well set off in a slope of grey shingle.

The Colesbourne Nurseries brought some remarkably rare and desirable plants, including a superbly beautiful deep blue meconopsis of uncertain parentage; Conandra ramondioides, with strangely crinkled fleshy leaves and loose heads of lilac potato flowers; Rheum Alexandræ, the Tibetan rhubarb, which makes lofty pagodas with pale primrose coloured tiles, and Polygonatum Hookeri, a pink Solomon's Seal.

Messrs. Gavin Jones showed Phyteuma comosum, just beginning to put out its purple horns of brown glass; Raoulia minutifolia, an attractive version in greenish silver of the better known R. australis, and Helichrysum frigidum, a silvery little bush with white everlasting flowers.

Dr. Macwatt brought some choice plants from his famous collection of primulas, including a very nearly blue auricula ("Blue Border") of great beauty; a very mealy P. capitata; the minute P. scotica; a good hybrid between P. marginata and P. auricula with many others.

Messrs. Cheal covered a flat stretch of shingle with delicately coloured flowers that made a picture of great charm and originality, the collection included Veronica filifolia; Geranium cinereum, forms of the alpine aster and alpine poppies.

Messrs. Bowell and Skarratt showed an extremely interesting and beautiful collection of terrestrial orchids, including Orchis militaris, in pink and crimson, and O. papilionacea with a broad and delicately veined labellum.

Messrs. Maxwell and Beale showed a very fine form of Tradescantia virginica alba with especially large, clear white flowers and a good group of Primula secundiflora.

Messrs. Scaplehorn showed the rare filmy fern Hymenophyllum Wilsoni; Haberlea virginalis, very much at home with Ramondia on a mossy rock face; Galax aphylla and Erodium guttatum.

Messrs. Wells showed Antirrhinum Asarina and good clumps of Primula sikkimensis.

Messrs. Prichard showed Androsace lanuginosa in pink and silver; Silene Hookeri, a wonderful little plant, almost overshadowed by its enormous, deeply cleft flowers of pure, soft pink; the very vivid form of Erinus alpinus "Dr. Henele," and other good things.

There were other exhibitors, but there is no more space left in which to describe their good plants.

HARDY PLANTS.

Of the plants which at the time of the Show were making our borders gay, the lupin and the pyrethrum were much in evidence, the Oriental poppy and the aquilegia poorly represented. On the other hand, the delphinium, flower of high summer, was displayed in some fine groups.

Messrs. Blackmore and Langdon's delphiniums were admirable in quality and beautifully set up. The outstanding novelty was Mrs. Foster Cunliffe, with huge flowers of helio-rose, pencilled blue, arranged on an immense and graceful spike. Other good ones in this group were Glory, almost flesh colour; Howard H. Crane, rosy violet, a veritable giant; Norah Ferguson; Millicent Blackmore; and the quaintly beautiful King Bladud.

Messrs. Bakers also had some really good plants of this beautiful flower, including Anne Baker, an immense single, pale violet and azure, with a large black "bee"—a tall spike and the flowers well placed; Jean, pale lavender mauve, tinged rose; Rev. E. Lascelles, still one of the most popular sorts and a very pleasing soft bluish mauve sport from it. Apart from the delphiniums, Messrs. Baker had some good astilbes, including the brilliant Granat, as well as Lupins Downer's Delight and Pink Pearl, and some fine pink seedlings.

Messrs. Hewitt and Co. made a table group entirely of cut delphiniums, using some admirable sorts, though the culture was hardly up to the standard of previous years. Some of the giants of the Wrexham strain were there—Monarch of Wales, Coquette, Violet Queen and Happy Thought; as well as the almost gentian blue Blue Bird; Great Strides, rosy violet and pale blue; and Mrs. Jessie Oldham, almost single, pale lavender, tinged heliotrope.

Messrs. G. Gibson and Co. of Leeming Bar had a particularly attractive globe-flower in Trollius Goldquelle. Other noteworthy plants were Gibson's Giant Orange Iceland poppy—remarkable both for size and substance; the Regal hybrid lupins: and Thalictrum aquilegifolium rubrum.

Messrs. Geo. Jackman, Limited, had the good double Pyrethrum Madeline, with a selection of lupins—Rosy Morn, Downer's Delight, Molly Fisher, etc.

Pyrethrums were well shown by Messrs. Kelway and Son. We particularly admired Flaming Star, a double red; Langport Scarlet; Lady Charnwood—both these singles, the latter bright rose; Lady Randolph Churchill, double blush; Princess Mary double rose; King Oscar, double crimson; and Lady Kildare, a beautiful double apricot. Peony Paola of lovely clear rose colouring was also noteworthy.

The quaintly beautiful Rheum Alexandræ was conspicuous in Mr. J. C. Allgrove's exhibit, which also displayed eremuri, pyrethrums and peonies. Of these last, the single bright crimson Sunbeam was noteworthy.

Messrs. Daniels Bros. included in a mixed exhibit a good strain of hybrid aquilegias;

Digitized by Google

while Messrs. R. H. Bath, Limited, showed among their tulips a useful lot of lupins and pyrethrums. Pyrethrum F. M. Peacock is a beautiful single scarlet.

The good things on the stand of Messrs. Wilson and Agar included Lupin Happiness, deep maroon purple; H. Marshall, lavender and primrose; the inevitable Downer's Delight; and an unnamed one of smoky slate colouring with gold or orange; colouring hardly possible except in a lupin or a carnation. Verbascum vernale is a pleasing little plant.

On Mr. Alfred Dawkins' length of tabling Scilla campanulata was shown in variety, as well as the brilliant double ranunculus.

The Chalk Hill Nurseries had some of their well known specialities—giant mimulus and pansies, for instance—as well as a number of lupins. Glow-worm and Queen of the West are two attractive sorts, the former of slate and buff and the latter of pinkish lavender colouring.

Mr. G. H. Dalrymple of freesia and primula fame has evidently gone in strongly for lupins. We noted King of the Blues, deep violet maroon; C. M. Prichard, orange buff; Eureka, smoky lavender; and His Majesty, a capital clear pink. A few clumps of the well known pink forms of Primula pulverulenta were included in the exhibit.

Messrs. Amos Perry included with their ferns and irises a few really good tree peonies. Here are three good ones: Nago-shin-abokin, a very vivid rose with an underlying hint of blue; Kokuriju Nishiki, crimson maroon; and The Tycoon, silvery rose with a tinge of salmon. This firm also exhibited Oriental poppies in variety.

Maytham Gardens had on show the beautiful Pæonia anemoneflora var. rosea, the silvery Anthemis arborea and Lupins Ruby King and Sulphur Gem, the former with claret and white, and the latter with long sulphur spikes and, obviously, tree lupin "blood."

Messrs. Maurice Prichard and Son had two exhibits, one in the tents, one outside. Among a good lot of lupins we singled out Brenda Prichard in bronze and orange shades as "something different." Anthericum liliastrum giganteum is an old plant, but a good one; the pink and typical forms of Primula pulverulenta are so good we can hardly have too many of them: and pyrethrums—shown here in quantity—are eminently useful for cutting. Of these last, Beauty of Lakin, double rosy crimson; Snow White, the best white singles we have seen; Hamlet, a bright rose single: Pink Pearl, an incurving shell pink single with a white zone; Aileen May Robinson, salmon rose; and Comet, large crimson scarlet, were noted.

Messrs. B. Ladhams had an interesting exhibit, in which we noted Peony Dawn, Verbascum denaiflorum, Hemerocallis Apricot and the golden H. Shirley.

Messrs. A. J. and C. Allen showed their aptly named Gaillardia Tangerine a splendid new comer to the world of herbaceous flowers.

Messrs. Amos Perry had a specimen stand of Oriental poppies, of which the scarlet fimbriated King George showed to best advantage. Other good ones included the salmony orange Mrs. Perry and Goliath, rich glowing crimson.

The only exhibit of violas and that a very good one, came from Mr. Wm. Yandell of Maidenhead. A few good sorts noted included Springwell Bronze, John Adamson, soft golden yellow, quite rayless; David Beattie, nearly black; Moseley Ideal, soft yellow, edged smoky lavender; Peggy Ramsey, chintz; and the golden Moseley Perfection.

An exhibit from Colesbourne Gardens, Cheltenham, included Pæonia lobata Sunbeam; P. elatior, red tinged with magenta; Rodgersia sambucifolia; Cypripedium Calceolus; Dodecatheon Meadia; the harebell poppy, Meconopsis quintuplinervia; M. Prattii; and Podophyllum Emodi Colesbourne var., the leaves heavily blotched with chocolate.

On Messrs. Waterer, Sons and Crisp's various exhibits were noted Roscoea cautlioides, its sulphur flowers quaintly beautiful; Primula japonica and variety salmonea; Delphiniums nudicaule and variety aurantiaca; Blue Bird, Norah Ferguson, Rev. Lascelles, etc.; Oriental Poppy Mrs. Perry in good form; Lupins Opal, Happiness (violet), Wargrave Beauty (rosy lavender below soft yellow above), and Dresden China; as well as Geum Fire Opal and a collection of pyrethrums.

Mr. Fred. G. Wood had the hybrid Aquilegia Helenæ; A. formosa, with orange and green flowers; Primula Helodoxa and P. japonica in variety.

Mr. G. R. Downer's considerable bank of lupins was full of character and some excellent unnamed seedlings of a most brilliant salmon orange will be in keen request. Among the standard sorts there was, of course, Delight. Other noteworthy sorts included Nublo, a really good violet blue; Pilgrim, silver lavender and cream; Lighthouse, a good pale pink; Hermit, violet maroon, a telling colour; and Artist, pastel shades of blue and pink—clear pale lavender at a little distance.

Down by the rock gardens, Messrs. Reamsbottoms arranged a little model garden of their brilliant St. Brigid anemones.

CLEMATIS.

A splendid group of large-flowered clematis was staged by Messrs. Geo. Jackman and Son, Limited. These included the showy banded Nellie Moser; Comtesse de Bouchard, a better plant by far than it looks at a flower show; the double white The Bride; Duchess of Edinburgh; the red Ville de Lyon; President (Jackmanni purple); the immense soft pink Fairy Queen; Jackmanni rubra; Princess of Wales; St. Julien; Lasurstern; Queen Alexandra, palest mauve of exquisite form and broadly banded with white; Sensation, lilac; the double lavender Belle of Woking; Lord Nevill, crimped purple; King Edward VII, lilac, banded rose; Beauty of Worcester, the well known double purple; and others.

HARDY FERNS.

As usual at Chelsea, Messrs. Amos Perry put up a large and beautiful exhibit of hardy ferns. Some of the kinds were, of course, exotics, albeit hardy ones, notably the Struthiopteris and some of the "flowering ferns" of the genus osmunda, but for the most part these quaintly crimped or densely plumed specimens are merely natural forms or careful selections of our native species. Polystichium angulare, for instance, is a species very prone to sport, as seen in such forms as P. a. divisilobum plumosum densum dissectum, a splendid, if long-named, form seen at Chelsea.

PALMS AND SUCCULENTS.

Although there was no specific collection of palms, as on many former occasions, various fine specimens were to be seen associated with other pot plants, and the attractions of the Orchid Tent were undoubtedly increased by the row of kentias alternating with tree ferns which were placed along the centre of the tent. A most decorative palm, Phœnix Rœbelini, in splendid condition was seen with Messrs. and Peed and Son's wonderful caladiums.

Mr. Sydney Smith had a collection of succulent plants which displayed the fascinations of their uncommon forms. He had nearly all the possible genera with a large number of distinct species. His chief plants were Mamillaria Scheideana, M. coronaria, M. micromeris, Echinocactus Grusonii, E. pilosus, E. chrysanthus and Cephalocereus senilis, with many species of euphorbia, echinopsis, cotyledons and echeverias.

AN INTERESTING COLLECTION OF CACTI, STAGED BY MR. SYDNEY SMITH.

FRUIT AND VEGETABLES.

An amateur with a fine exhibit was the Hon. John Ward, Chilton, Hungerford, who staged a collection of choice melons, peaches, nectarines and grapes.

Fruit trees in pots from the nurseries of Messrs. T. Rivers and Sons, Limited, provided a distinctive and attractive show, in which nectarines, oranges and lemons were the particular feature.

Exhibits of fruit were confined to a collection of strawberries which reflected the greatest credit on the raisers, Messrs. Laxton Brothers, Bedford. The fruits were of a uniformly large size and beautifully coloured in shades ranging from bright scarlet to dark red, and while their character did not contribute to an artistic display, the arrangement of the table left nothing to be desired. The variety which attracted most attention was the firm's 1927 novelty Duchess of York, a maincrop strawberry with British Queen flavour. The fruits were ideal in

Digitized by Google

size and colour. Robust, a maincrop sort, is another meritorious new strawberry, and those growers who are familiar with the popular Royal Sovereign will recognise in King George an advance on the older sort. Among other varieties included in this interesting exhibit were The Duke and Marechal Foch.

Considering the early season of the year, the exhibits of vegetables were entitled to rank among the successes of the Show; indeed, it is difficult to say whether the excellent quality of the products or the number and variety of the dishes commanded most admiration.

Of Messrs. Suttons' exhibit it may be truly said that the Reading firm succeeded in making a vegetable display beautiful. Even the common garden pea and the dwarf bean looked more attractive and less familiar when arranged in artistic form, and the once commonplace stand was transformed into an original and educative object-lesson.

New varieties and forms of vegetables were the chief characteristic of Messrs. James Carter and Co.'s exhibit. Here novel colourings were the fashion, for there were mottled radishes, yellow and white cucumbers and golden beans that were hardly recognisable in their latest and more radiant garb. Yellow and red currant tomatoes of tiny size added to the attractions of the group, and the cauliflowers were particularly fine for this time of the year.

A comprehensive collection of vegetables of excellent quality was exhibited by the Hon. Vicary Gibbs, Aldenham House. Peas, French beans and tomatoes were particularly good.

OUR PHOTOGRAPHIC COMPETITION

In view of the number of excellent photographs which have been received from readers, many of which are as meritorious from the gardening as from the photographic standpoint, it is impossible to publish as many as we should like. Indeed, it is with no small difficulty that we select those to which awards shall be made. Numbers deserve publication for more than one reason. We propose to retain, unless the senders signify their wishes to the contrary, a selection of the more attractive photographs and to publish them from time to time, independently of the weekly competition announcement, when awards will be made under exactly the same conditions as if the photographs were published in connection with the competition itself. In connection with the receipt and return of photographs we would direct readers' attention to Rules 6 and 7.

This is a photograph of my rock garden, taken two years after planting. It is made on a slope facing east, about a mile and a half from the foot of Lake Windermere. There is quite a variety of plants growing in the garden, including veronica, white broom, foxgloves, royal fern, Geranium lancastriense, G. sanguineum, Cistus florentinus, Veronica rupestris, Menziesia alba and Viola cornuta. There is a large and decorative patch of woolly thyme in the left corner, with Veronica Guthrieana and rock roses on the right.

The Guinea Photograph, sent by MRS. CHEYNE, *Newby Bridge, Ulverston.*

This is a novel idea of using a bird bath or any other suitable garden ornament. Although not strictly a garden picture, I think it is most charming and an added beauty to the garden. Ornaments placed at vantage points throughout the garden undoubtedly enhance the design and assist the appearance.—MRS. HAMILTON, *Henley Park, Henley-on-Thames.*

Award of 5s.

[*This is, we agree, a particularly happy illustration and fully worthy of an award.*—ED.

Digitized by Google

Canterbury bells, especially the old-fashioned cup-and-saucer varieties, are among the favourite flowers of the garden. They can be used in many parts of the garden, but here the effect is a particularly charming one, since—as is shown—they have been planted in the mass round the base of a tree and allowed to grow at will. With the background of foxgloves there is an atmosphere of an old-world garden. The Canterbury bells thrive very well under the half shade of this tree. —MISS E. WINGFIELD, *Heavitree, Exeter.* Award of 5s.

There is little doubt that a double white cherry tree, well placed, adds considerable beauty to the surroundings of a garden. Placed at the side of the lawn, as it is here, and the bed underneath planted with spring flowers, pink daisies, wallflowers and pink tulips, it looks most effective.—LADY THORNEYCROFT, *Bembridge, Isle of Wight.* Award of 5s.

This illustrates rather an attractive way of using an ordinary stone pillar as a garden ornament as well as a sundial. It can be made quite an effective focus point in the garden lawn by placing it in a central paved position and planting around it with trailing plants such as cerastium, arabis or aubrietia. —MR. C. W. PYLE, *Harlow, Essex.* Award of 5s.

Three years ago I purchased fifty Inglescombe Yellow Darwin tulips and planted them out in beds running up to the front of the house. As a groundwork to the beds I planted white saxifrages. The bulbs have always been planted with a little sand and Wakeley's hop manure below each, and lifted annually after the foliage has turned yellow. They are stored for the summer and replanted in late October. This treatment seems to suit them, as this year the display is a particularly fine one, and only three rows were planted thickly. —MISS L. M. ORR, *St. George's Hill, Weybridge, Surrey.* Award of 5s.

WORK IN THE FLOWER GARDEN

Summer Treatment of Cyclamen.

THERE is little doubt that the best results are secured by making an annual sowing of cyclamen, but this is not always convenient. With proper treatment during the resting period the old corms will flower very freely for many years. When the flowers are quite over, lessen the supply of water so that the growth may be induced to lessen gradually. It is not, however, advisable to withhold water entirely, even when the corms are quite dormant. The best plan is to put the pots in a well shaded frame and give water about once every ten days. In July, before there are any signs of new growth, shake out the corms and re-pot them in a compost of good loam and leaf soil, taking care to keep them sufficiently high to prevent the water settling in them. Keep the cyclamen in the frame until late September, when they may be removed to a light position in the greenhouse. If given careful treatment at the present time the plants will flower successfully during the winter months.

A Fine Hardy Shrub.

ONE of the most attractive brooms, is Cytisus albus, forming a delightful object in May, when the white blossoms appear in remarkable profusion on the long graceful branches. Though often grown among other shrubs, it is worthy of a prominent position by itself, for then its natural grace and beauty are fully displayed. If allowed to grow as it pleases it becomes somewhat straggling in a few years, but if the branches are cut back after flowering, the portions left will produce shoots for the following season's display, and the plants are kept in better condition thereby. A sandy soil and sunny position are regarded as ideal, but this broom will grow in heavy soils and in exposed positions, to which the plant in the illustration bears witness.—J. C. C.

The Musk Rose.

OF all rambling roses, the musk rose, Rosa moschata, is, perhaps, the most satisfactory. It is deliciously fragrant, and its white flowers, faintly tinged with pink, have a multitude of golden stamens, and are borne with extraordinary profusion in immense corymbs. Once established, it needs no pruning and, given a suitable support, will climb to a height of 30ft. or more. The beauty of the rose is, perhaps, seen to best advantage when rambling over a dark-foliaged evergreen, such as a yew. That the soil in the vicinity of a large tree will need improving before putting in the rambler goes almost without saying. A hole should be taken out to a considerable width and depth, and filled in with good loam enriched with well decayed manure—preferably cow dung. Should the natural soil be stiff and heavy, care should be taken that there is no danger of the roots becoming waterlogged, for it is possible for this to occur even near the roots of large trees. Drains near tree roots do not function long, so to be on the safe side in such a case plant the rose on a slight mound. Near large towns or in very bleak localities it is wiser to employ the hybrid musk rose The Garland, which, except that it is double, has all the good points of the species with greater powers of resistance against unfavourable conditions. The musk rose is usually in full flower in the south and midlands by the end of June. The Garland has a rather later flowering season.—MIDLANDER.

Growing Heliotrope in Tubs.

NOW there are so many brightly coloured flowers at our disposal, the sweet heliotrope is apt to be overlooked. It is an old-fashioned flower which is not met with as frequently as it should be, because few people know what can be made of it with careful culture.

Heliotrope is usually seen in small pots, with a few clusters of pretty, fragrant flowers; but it can be grown on until it fills a large tub. By this time the plant will be about 5ft. high and covered with trusses of bloom.

The culture must begin with a small plant, preferably a strong grower like H. corymbosum; although other varieties respond well to the same treatment. But no dwarfs or weak growers will answer the purpose, and H. corymbosum is a good grower and easy to obtain.

ONE OF THE MOST ATTRACTIVE BROOMS, CYTISUS ALBUS.
It can be grown in almost any position.

The plant selected must be young and in vigorous growth. As soon as the roots touch the sides of the pot, transplant into one a size larger, being careful to disturb the roots as little as possible. Continue this treatment until the plant can be put into a tub 2ft. in diameter. Any bloom must be carefully pinched out as it appears, and the strongest shoots trained upright to form the main stem. The side shoots are tied to a fan-shaped trellis, all not required are cut out.

It is best to begin this culture in the summer when the pot can stand out of doors. Give plenty of water and be careful not to let the sun heat the pot. For this reason wooden tubs are better than pots, and as soon as the heliotrope attains any size it is better planted into one.

The plant should be kept growing all summer, never allowed to flower, and occasionally given weak liquid manure. It should be a good size by autumn and must then be removed indoors to a warm, sunny position before the first frost, and grown on as before. During the first winter allow the wide side shoots to give a few clusters of flowers, but it is essential to success to keep the leaders to wood.

If the same culture is continued for five years, the heliotrope should be from 3ft. to 5ft. high, with a stem as thick as a man's finger and carrying as much bloom as anyone could wish. It will then only require watering and sufficient pruning to keep it in shape.—H. ALLAN.

Remember to Sow Wallflower Seed.

AMONG spring bedding plants the wallflowers occupy a high position, and deservedly so, when we remember their delightful fragrance, their free-flowering qualities, the ease with which they can be successfully cultivated, and their usefulness for beds, borders and the flower garden generally. It has been stated that July is a good month for sowing wallflower seeds; but if left till this date it is impossible to obtain fine plants by October. May or early in June is a much better time for sowing the seeds, and these should be in lines 1ft. apart. When large enough the seedlings are transplanted in firm soil from 9ins. to a foot apart, and directly they are established pinch out the centre of each plant, no more stopping being required. If the ground is hoed occasionally the plants will grow freely. Wallflowers with their wealth of blossom can be associated with other plants, but for beds I prefer them alone with, perhaps an edging of forget-me-nots or arabis. Like many other popular flowers, the number of named varieties is increasing, a fact which must be a problem to the amateur or beginner when making his selection. A few varieties that always give a good account of themselves include Fire King, a brilliant vivid orange, especially when viewed from a distance on a bright day. Height, 15ins.

A dwarf and compact plant is Orange Bedder; it is a difficult colour to describe, the flowers opening a rich orange and toning off to apricot yellow. Height, 12ins.

This spring I have grown these two varieties intermixed, and the effect is charming, while the slight difference in the height takes off the flat appearance of the beds.

Blood Red is always a favourite if a good reliable strain is obtained; but for two years my plants produced flowers striped with yellow, and now I rely on Giant Vulcan, a dwarf rich crimson variety. Cloth of Gold is a rich yellow and a very effective bedder; while another good yellow is Belvoir Castle.

There are other forms, but the above selection will suffice for most gardeners.

A warm sunny border planted with a few early-flowering wallflowers will be an asset about Christmas-time if the weather proves mild, when the following varieties often begin to bloom. Among the best will be found Phœnix, a rich chestnut brown; and Yellow Phœnix is an excellent companion to the type.

Cherianthus Allionii, or Siberian wallflower, is quite distinct from those already quoted, but it requires the same treatment and is useful for beds and borders. Moreover it has a more extended flowering period, therefore it should be planted where there will be no need to discard it for summer bedding. A patch on the rock garden is very effective, especially if planted where the glorious orange flowers are brought nearer to the eye. When in bloom this plant is from 9ins. to 12ins. in height.

Cherianthus or Erysimum linifolium, the mauve alpine wallflower, produces its heads of clear mauve flowers in May and June, and is an excellent subject for small beds and the rock garden, but wherever possible it should also be planted on a low retaining wall. Here it grows freely, and produces plenty of seeds, the seedlings eventually appearing in all directions.—T. W. B.

A BOWL OF GARDEN PINKS.

FEW flowers are more popular in our gardens than the hardy border pinks. They show a wide range of the most attractive colourings whose purity is almost unequalled. Other advantages that they possess are easy culture, hardiness and long season of flowering. Moreover, they will grow in almost any soil and require little attention after planting, except the removal of withered blooms to promote longer flowering. In the garden they are best used for edgings to a path, being ornamental both in flower and foliage. They also look most attractive planted in small beds.

THE GARDEN

VOL. XCI.—No. 2897. JUNE 11, 1927. PRICE TWOPENCE.

ALLOTMENTS MADE BEAUTIFUL

HOW often one hears the complaint that one would rather see a patch of grass or a field, than a group of allotments. This should not be. Yet the complaint is justified in many instances, for there are allotment sites that have come under our notice that have been anything but pleasing to the eye, even when well cropped. At their best, allotments look what they are; simply a mass of cultivated vegetables, and the majority of vegetables have not even attractive foliage. But why not a few flowers to brighten up these dull, monotonous patches. Apart from the valuable asset to the country of food production, there is no reason why groups of allotments should not be some of the most beautiful and coveted places wherever they are situated.

Now look at the accompanying photograph. This shows a corner of a group of allotments, which, in itself, is a beautiful garden of flowers. Why should not a similar array of colour be a regular feature on all such sites? One hears of cases of objection by ratepayers and others to certain groups of allotments. Here is an opportunity for allotment associations to take up the floral side of their interests and so put "another string in their bow," for the retention of their land.

We know that a movement for the inclusion of flowers on allotments is already on foot, but there is need for greater co-operation, not only among societies, but among the members. Why not have a rule to the effect that members should allocate a portion of the plot to flowers?

We see no reason why allotment grounds could not be so decked with flowers—without any appreciable reduction in the area reserved for the cultivation of vegetables—that the public could be admitted on certain days, as is done at certain private gardens, to see the wonderful display of flowers grown by allotment holders. Besides the prestige created in the public mind, this could be made a means of adding revenue to an association's exchequer.

This Week's Work

For Gardens in the South and Midlands.

Stake all tall-growing herbaceous perennials and keep the borders hoed regularly.

Earth up potatoes and sow peas, runner beans, lettuce and spinach.

Plant out celery, ridge cucumbers, Brussels sprouts, vegetable marrows and leeks.

Thin out turnips, carrots and lettuces.

Feed with weak liquid manure roses, tomatoes, chrysanthemums in pots and bush fruit.

Thin the fruit of apple trees.

Apply weed killer to paths.

Give perpetual carnations their final potting.

Temple Gardens Exhibition.

THE London Gardens Guild will hold its second large exhibition of flowers grown in London gardens in September next (3rd, 4th and 5th) in the Temple Gardens, which it uses by permission of the Benchers of the Inner Temple.

The exhibition is mainly for the amateur. A few trade exhibits will be there, but the bulk of the exhibition will be staged by amateurs belonging to Gardens Guild branches and affiliated societies. The schedule offers awards in the form of medals (no prizes are offered, either in money or kind) for individual exhibits of flowers, and also for corporate displays from various horticultural societies in and around London. The Exhibition is being organised with the help of the *Daily Express*, which assists the Guild movement also in connection with the Garden Championships. In addition to providing the medals, the *Daily Express* is also offering a silver challenge shield to the Society whose members secure the highest aggregate number of points.

Schedules of the Exhibition, which is open to all amateur gardeners within the Metropolitan Police area, will be sent on application to the Hon. Organising Secretary, 124, Walworth Road, S.E.17.

The Silver Cup for Peonies.

THE competition for the second of three cups presented by Mrs. Edward Harding for award for the best exhibit of three flowers of each of six varieties shown by an amateur, will take place in 1927 on June 21st, at the R.H.S. Fortnightly Show at Vincent Square.

The pinks illustrated on this week's front cover are a few of the varieties of Mr. C. Herbert's well known strain.

This Week's Work

For Gardens in Scotland and the North.

Plant vegetable marrows.

Give apple trees a light mulching of half decayed manure.

Thin out annuals with a liberal hand.

Dust hellebore powder on gooseberry bushes when the foliage is wet.

Begin transplanting leeks.

Sow swedes for winter use.

Renew window boxes.

Complete planting chrysanthemums, dahlias, antirrhinums, etc.

Spray aphis-infested rose and fruit trees.

Plant out seedling carnations.

Trim box edgings in showery weather.

Plant savoys and kale as ground becomes vacant.

A TINY POOL FOR THE SMALL GARDEN

II.—HOW TO MAKE AND STOCK IT.

HAVING made up our minds as to the placing of the pool (see THE GARDEN for May 21st, page 322), we have now to consider the materials needed and the actual work of construction.

Let us take as an example the recessed dripping well illustrated at Fig. 2 in the previous article, and which is shown in vertical and horizontal sections (the latter at ground level) in Fig. 5. Having decided upon the line of the wall, the exact position of the tank in the wall and the finished ground-level on the lower side—say the level of the pavement—we may proceed to set upon the ground the area included by the "dot-dashed" line PQRST.

Let ST (Fig. 6) represent the line of the wall face at ground level, and U the point where it is decided to have the "drip." We next measure off 6ft. 7ins. from U towards S, and put in a peg (point V). Similarly we fix and peg the point W 6ft. 7ins. from U. At V and W we set up cross lines at right angles.

Measure off at each end behind the wall line 1ft. 7ins.; this will determine the points P and Q (Fig. 5). Points R and T will now easily be fixed from the dimensions given in Fig. 6. The arc S is found by describing a segment of a circle with a line attached to a peg driven in at a point 4ins. in front of the point U on the wall face. The radius of the segment should be 6ft. 5ins.

ONE OF THE TINY GROWING WATER LILIES, SUCH AS N. PYGMÆA LOOKS WELL IN A SMALL POOL.

Excavate the whole of the area PQRST to a depth of 3ft. 10ins. below the finished ground level. "Nick" the inner lines of the walls with a spade. A square about 12ins. each way taken out in the centre is a convenient position for the drainage sump; soil excavation to a further depth of 6ins. or 8ins. being necessary. The amateur pool-maker, however, will find it of considerable assistance if he moulds his concrete for this around some deepish box already in his possession, which will probably be oblong, not square.

Take the outside dimensions of this box and excavate for the concrete 1ft. wider and longer. Next slope the concrete bottom inside the wall lines very slightly towards the sump hole; a maximum fall of ½in. will be ample. The bottom, if quite firm and solid, is now ready for the concrete. If, however, the site has recently been made up or should be bottom prove to be unstable sand, all possible consolidation should be effected, and it will be well to lay down 6ins. of concrete instead of the 4ins. which normally suffices.

The sump is, of course, provided to enable the tank to be emptied periodically for cleaning purposes. This, after the first few weeks, will seldom be necessary, but as such a tank will hold somewhere about 800 gallons of water, the task, even though a portable pump be available, will not be a light one. It follows that, if the bottom of the tank is above the level of a near-by and accessible drain or ditch, it will be well worth while to provide an emptying drain. The bottom of the tank should then slope gently to a convenient point for bringing the pipes under the wall foundation and, instead of the sump, a proper stone valve—procurable from any builders' merchant—should be fitted.

We come now to consideration of the concrete for which the materials should all be to hand before the excavation is undertaken, otherwise rain storms are likely to bring in the sides of the excavation and to make work unpleasant, even if baling out does not become necessary. For the purpose in mind a good concrete is made of three parts by measure good clean brick rubble—*i.e.*, broken bricks free from mortar rubble—broken small enough to pass a 1½in. sieve, one part of clean, really sharp sand and one part of good Portland cement. If brick rubble be scarce, half the quantity only may be used, and the remaining one and a half parts be made up of granite chippings, hard stones broken to the gauge given, or even clean clinker ash.

The materials should first be thoroughly mixed while still in a dry condition, then water be added sparingly to the heap, and the heap turned and turned again, with sparing additions of water until the whole is of the consistency of rather wet mortar. If the brick rubble seems dry in the first place, it is well to water it thoroughly and let it drain before the initial dry mixing. It is better and easier to mix the materials in fairly small quantities—say three barrows of brick rubble and one barrow each of sand and cement—at a time.

First place a layer of cement 4ins. thick in the bottom of the sump hole, and ram until it is quite solid While this is drying a little concreting of the tank base may be commenced, keeping away from the sump hole. Lay down 4ins. of concrete all over, keeping the wall footings quite level and sloping what will be the tank base to follow as near as may be the contour of the shaped earth beneath. As soon as the cement to the sump bottom has set sufficiently—it should not be hard—the box already provided for a mould may be placed centrally and concrete be packed around it to form the sump walls, which will, of course, project some 4ins. above the earth floor of the tank. The concreting of the base may now be finished. And the work to date will have absorbed about 3½yds. of concrete. The base should be allowed to dry sufficiently to be walked upon without taking foot-marks before the walling is commenced.

The walls below water may be of concrete, but they will not look so well, and it will in that case be necessary to build up "boxes" with timber in which to mould the concrete. The amateur will do best to make the sides of the stone or brick of which the above-water walling is made. The plan allows us to "batter," that is, slope back, the walls which have to retain the surrounding earth at the rate of 8ins. in 7ft. If we tack to one side of the plumb rule a strip of wood so planed that it tapers evenly off to nothing at the base of the rule and is 2ins. away from it 1ft. 9ins. from the base, we can easily arrange this batter. Bed the first

course of stones on the wall lines, selecting, if possible, stones a little deeper at the front than the back, bedding them in cement mortar made to a strength of "two and one"—that is two parts of clean, sharp sand and one of cement—and setting them so that their faces fall back to the line of the batter. As each course is laid, pack in solid behind with cement concrete as already described. When we reach the level of the side-wall "footings," it will be well to put a block of concrete about 2ft. long of the width of the wall-footing proper (1ft. 11ins. as shown, Fig. 5) and quite 8ins. deep; this to prevent unsightly cracking at this point as the work "settles." An overflow pipe to a drain or soak-away must not be forgotten when the proper height is reached.

Once the work is carried above water-level, the retaining walls may be finished as desired, but it will, perhaps, be as well to bed the stones in cement, except for occasional places for planting, to back them with soil, and to rake back the joints when partly dry with the point of a trowel or a small iron bar. Any part of the wall which has to show both faces—that is stands above terrace-level—will need cementing on both faces, and the capping will, of course, be put on in cement.

The recess for the drip should start just below water-level; a lead head to mask the water pipe can be obtained or a roughly chiselled "lip" of stone may be set to project a couple of inches. A rotary jet may be fixed, if desired, to the spray. When tank-walling is finished, the concrete bottom should be faced or "rendered" with a thin (¼in.) layer of cement mortar ("two and one").

The following tools will be found to be essential: A 7in. or 7½in. bricklayer's trowel, bricklayer's hammer, plumb-rule and bob, spirit-level and straight-edge, and a good shovel. The use of a wheelbarrow and odd lids or boards for "hods" may be understood. For lining the pool and building the terrace wall within the area shown in Fig. 5 (that is excluding the flanking walls, of which we have no running dimensions) some 6 or 7 tons of coursed rubble walling stone will be required; or in brickwork and employing 3in. bricks, 800 bricks would be needed. In either case 19ft. 6ins. run of 16in. self-faced hard Yorkstone coping. For the concrete 6yds. (loads) of brick rubble, one load of sand and twelve bags of cement would be requisite, and a further two bags of cement and a few hundredweights of sand for the walling above water-level for building up the stonework face and for "rendering" the bottom. The quantities given are, of course, approximate, as the materials needed will vary somewhat with the character of the stone employed. In particular more concrete will be needed if bricks are used for the facing. Pools of similar area but without the walling behind will, naturally, take a similar amount of concrete, but less walling stone and jointing material.

The construction of the informal pool will follow similar lines, but the rocks below water-line will follow natural not "walling" lines, and the concrete for the sides will be better made of smaller materials—to pass a ¾in. riddle—so that it may be more plastic in use. Again, the sides, being dished and to some extent strengthened with stone, can be moulded up to shape from the, in this case, irregular bottom (Fig. 7). Any bogland must be included in the area to be concreted, and the rocky wall dividing it from the pool proper be built up against a bank of good turfy loam, peat and sphagnum moss over a foundation of rough stones or brick-bats. The little pool and double bog shown in Fig. 3 (page 322) would require about 2½yds. of concrete and from 1 to 2 tons of rockery stone for its construction.

The *planting* of tiny pools is restricted by the necessity of using kinds which do not overwhelm and dwarf so small a piece of water. Two really tiny water lilies are Nymphæa pygmæa (white) and its variety helveola with sulphur yellow flowers. Neither of these should have more than a foot of water above their crowns. Frœbeli, with deep crimson flowers, is small-leaved and free to blossom, and other moderate growers include all the Laydeckeri set. The deep rosy crimson N. Laydeckeri purpurata with deep orange stamens is especially effective. The fragrant varieties of the species odorata, some with white and others with sulphur yellow flowers, are also moderate in growth. For very, very small pools a good substitute for water lilies is our native water buttercup, Ranunculus aquatilis, with myriads of white flowers. The flowering rush, Butomus umbellatus (also native) is good potted up and grown in the formal pool. It has stately foliage and bears agapanthus-like umbels of pink flowers.

Other good aquatics are the floating Cape hawthorn, Aponogeton distachyon, which however, needs keeping in bounds; the bog bean, Menyanthes trifoliata, with much-fringed blush white blossoms; Limnanthemum peltatum (Villarsia nymphæoides) with floating foliage and golden yellow flowers—a plant for shallow water; the double arrow-head, Sagittaria variabilis fl.-pl.; the lesser mace-reed, Typha minima, also for shallow water; and the beautiful arum lily, Richardia africana.

There are a number of suitable plants for growing round the edges of an informal pool. Siberian irises, astilbes, primulas, and spiræas are well adapted for such a position. Astilbe Pink Pearl is one of the most attractive of its class, and Primulas Beesiana, Bulleyana and the various forms of japonica are all easy to grow. The globe flowers (trollius) are very attractive, while the funkias, with their glaucous green leaves, are effective both in flower and foliage.

For a formal pool the nymphæas are best potted up in good turfy loam and well decayed manure—preferably cow dung—with proper "drainage" just as if they were to remain above water. The pots (8in. size will do well for the smaller growers) may then be stood upon the pool bottom, or raised, if necessary on stands of brick or stone. By treating the other aquatics similarly it is easy to achieve the desired balance for effect and to keep the pool-bottom clean. In the case of an informal pool, all the kinds mentioned may be planted out in a layer of good loamy soil in the pool bottom, but the precaution should be taken of weighting down the roots by tying stones to them, otherwise the plants are likely to float to the surface before they can become established.

To keep the water of a pool—especially of a little pool—sweet and wholesome, and to prevent it from degenerating into a breeding place for midges, animal life should be introduced and made at home. In pools of the size we have been discussing it would be well to put in six or eight gold fish, procuring these from a source where they have not been "coddled" in warm rooms. A few water snails and newts may also be dropped in. Fish need food, and it may be well to feed the gold fish for a time until insect life upon and in the water becomes established. They also need shade, and such plants as Ranunculus aquatilis are invaluable for providing this, but a few rough pieces of stone on the pool floor should be included in addition. Before planting or stocking with fish the pool should be filled, emptied and refilled at least twice, leaving it full on each occasion for several days. Also the water should be partially changed—by running fresh water in—to a much greater extent for the first month or two than will be necessary or desirable afterwards. It should be said that the sooner the pool can be filled when the concreting is finished the harder and better the cement will set. In really hard frost it will be well to cover the unbroken areas of ice with bracken or other light material before it becomes too solid, otherwise its expansion may damage the concrete. R. V. G. W.

A TINY POOL WELL PLANTED AND IN CHARMING SURROUNDINGS.

If you like "The Garden," tell your friends about it.

TAKE CUTTINGS OF CATMINT

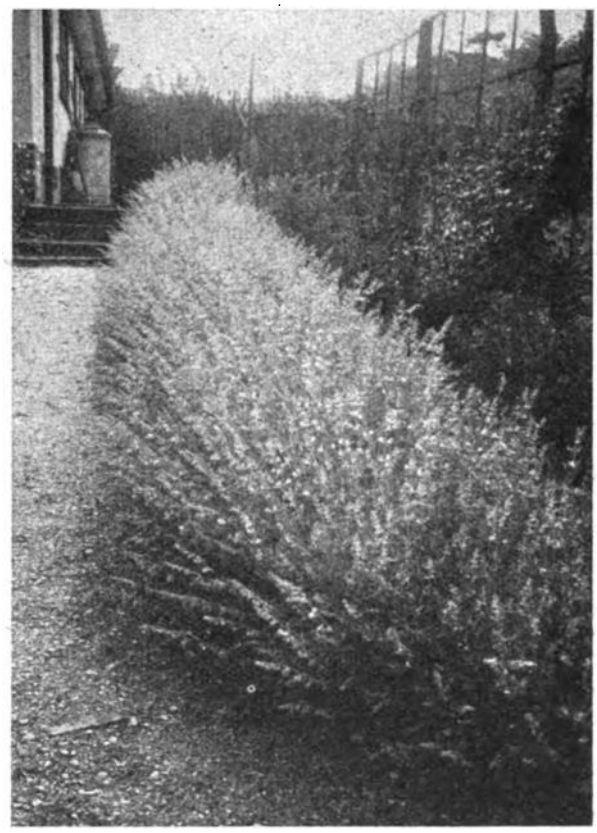
IT is peculiar how opinions on the merits of Nepeta Mussini appear to differ. For my garden there cannot be enough. I have two hedges of it 60ft. in length, one bordering a path leading to the back door, and another edging a small lawn facing the front of the house. Last season I raised nearly three hundred good plants from cuttings taken in July, which were planted out in the autumn in groups of three in the long herbaceous border, allowing 2ft. between the plants, between which I planted three rooted cuttings of a rosy pink antirrhinum which will flower at the same time as the nepeta. The effect when looking along the border should be very striking, for the long, lavender spikes — or misty blue if you like — form an effective foil for almost any pink flower. Next year the nepeta will require all the ground to itself, as it increases very rapidly, and will make bold groups of colour showing up well against the green background of the growing perennial shoots of asters, etc.

With me, in Berkshire, it commences to bloom about the middle to end of May, even in such a cold, backward season such as this. The first flowering spikes may disappoint those who are growing the plant for the first time, because the flowers are spaced at rather wide intervals on the stems, and more foliage will be in evidence than will be seen a fortnight later. Then it will be difficult to find any at all, the row presenting an unbroken wall of lavender blue spikes beloved of bees, which maintain an incessant hum from daybreak to sunset.

That is how the plant behaves in my heavy clay soil over chalk, remaining in bloom well into July, and will give quite a good showing of secondary bloom in September if the flowering spikes as they go out of bloom are cut ruthlessly down to within a few inches of the ground with hedging shears.

And yet I met a man the other day who told me that he had instructed his gardener to root out every piece from his garden! Naturally, I enquired his reason, and learned that it was because it was such nasty, straggling stuff. Well, there is some truth in the statement if the wealth of bloom is allowed to fall about in its own sweet way; but, if the old growths which die down in winter are allowed to remain, they will efficiently support the next season's flowers, or twiggy sticks may be inserted along the row, very much in the same manner as support is given to plants in the herbaceous border, except that nepeta only requires sticks measuring some twelve to eighteen inches in height. A better method of supporting the blooms is to nail a length of foot-wide, small mesh wire netting on short stakes driven into the ground, putting the support in place soon after the new growths push forth. The shoots will grow through the netting, which is quite hidden by the time that the plants are in full bloom.

In July, when the flowers are going over, the plants will commence to push forth an abundant supply of soft new growths, which make splendid cuttings if pinched off and inserted in sandy compost in a shaded cold frame. The growths should be about 3ins. long and should be dibbled into the frame or boxes of sandy compost, inserting the cuttings about 2ins. deep. The lower leaves may be removed if desired, and the shoot trimmed just below the bottom pair of leaves. So doing makes for greater success in the striking, but nepeta will strike readily if inserted just as the shoot is pinched from the plant. Keep the frame moist and shaded for the first week, dewing over at night, and the majority will have rooted in three weeks. The shoots may flag for the first few days, but will soon become erect if kept moist. The tips of the plants used for cuttings in this way are really flowering shoots, *i.e.*, if they have been left on the plant they would have produced flowers. As the cuttings send out roots these flowers will develop and should be pinched off, for pinching encourages the dormant, underground buds to push out into new growths, which rapidly produce a good bushy plant by early September.



AN EDGING OF NEPETA IN FULL FLOWER.

After flowering the soft new growths can be pinched off. These make excellent cuttings if inserted in sandy compost in a cold frame.

Where a large increase in stock is desired, it may be difficult to find the requisite number of soft shoots in July. These can readily be obtained if a number of plants are cut back to within a few inches of the soil. A month later there will be an abundance of shoots admirable for use as cuttings, very few of which will go to bloom while being propagated. The only objection to this form of cutting is that they are of a softer nature than those produced by the natural growths, and are apt to damp off if the frame is kept too close. If, however, the shoots are allowed to develop on the plant, these can be pinched off in September and inserted with every hope of success. Such late strikings make sturdy little plants in time for late autumn planting, and will flower very well in the following June and July.

When putting these plants into their permanent positions do not make the error of planting too close together. At least 2ft. of space should be allowed between the plants, and nothing should be planted behind or before them unless it is at least a foot away. That will suffice for the first season, when a single antirrhinum plant may be planted between the nepeta in the rows. In the second year nothing should be planted between, or it will be hopelessly swamped by the nepeta growths, and no plant should be inserted either behind or before the nepeta unless 2ft. away from it.

Inexperienced gardeners cannot realise the growth made by this perennial in its second year. During March the shoots are just pushing through the soil. Harmless, soft growths they then appear, with apparently plenty of space for a few flowering plants in between. At the beginning of May, the seemingly harmless shoots have spread themselves considerably, and in mid-June, when the plants are in full flower they form a veritable hedge. The accompanying illustration is of a hedge of Nepeta Mussini in my garden. It is in full flower, and shows the amount of growth which has been made by the second season. C. P.

PLANTS FOR PORCHES

IN the building of quite a number of modern houses there is a disposition to follow the practice of erecting porches, and in this respect it is carrying into effect the idea seen in many old country homes. These porches not only act as a shield in bad weather, but serve the purpose of shade in summer. One notices frequently how the lover of a garden takes the opportunity of growing climbing plants over and around these structures, that, in their season, are festooned with flowers and trailing shoots. Time and again one comes across the white sweetly scented jasmine; Clematis Jackmannii, with clusters of purple flowers; or Clematis Flammula, smothered in the early spring with its myriad white blossoms. Roses, too, are great favourites, and though ramblers are frequently planted, the space around a porch being limited, one finds better results when sorts noted for longer blooming are employed. I have come across not a few old-type roses so grown—William Allen Richardson and Gloire de Dijon, for example — and not long since I saw on an old porch a rose that is seldom met with to-day, very sturdy and one which used to be frequently recommended for cold and exposed situations, *viz.*, Amadis, a semi-double purplish crimson. For rich perfume, what can rival in its time of blooming, clusters of honeysuckle? In warm localities and sunny positions one remembers the beauty of the drooping racemes of wistaria, and the exuberant growth of passiflora. These can be planted in spring because they can always be procured in pots, as can also the creamy white-flowered Solanum jasminoides and the quick-growing Cobæa scandens, both of which are of service in enveloping a porch in a sunny position. Planting of these also can be done in spring, and it is scarcely necessary to say more than that, having regard to their permanency, 2ft. or more of good soil—loam and old manure—should be provided for the roots.

Annuals also serve a purpose in furnishing a porch with summer beauty. We may have convolvuluses in blue and purple, and crimson and white, or a wealth of yellow blossoms amid foliage of tenderest green, by sowing seeds of Tropæolum canariense; or we may ensure gayness for months by dropping in a few seeds of nasturtiums, which will yield flowers in brightest tints. F. W.

SCENTED GLADIOLI

In this article are described a number of scented species of gladioli which are found wild in South Africa. Many of these have been introduced to this country, and in course of time our modern garden varieties may become scented when crossed with these charming species.

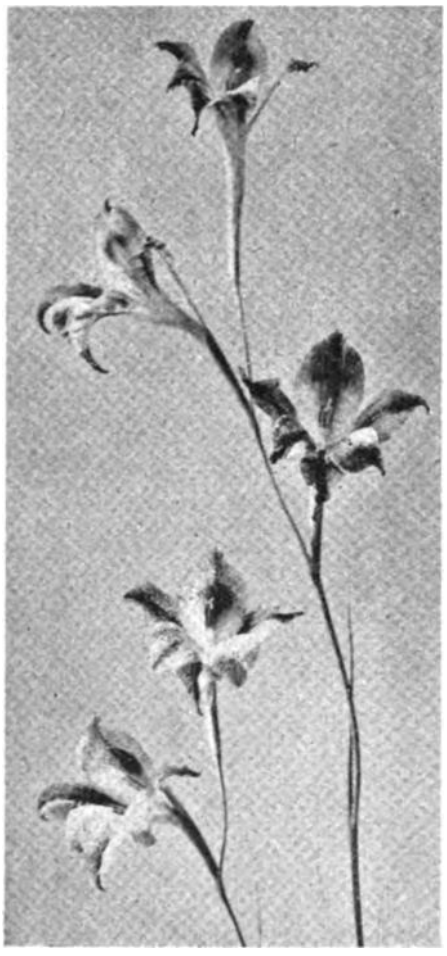
IS the scented gladiolus merely a dream of optimistic gardeners? Mr. Kelway tells us in the "Gladiolus Society's Annual" that Gladiolus tristis was introduced into Europe in 1745, and I rather suspect that it has been looked on as *the* scented gladiolus of South Africa.

Gladiolus tristis is a wonderful flower, and it must be conspicuous, for it is one of the very few that are known to the average South African. I think one could not very well overlook it, for as it blooms in my garden it stands over 5ft. high, with a spike of fifteen to twenty pale yellow blooms on a delicate stem bowing and waving in the breeze, and when it opens at sunset its delicious scent fills the evening air. It seeds freely and germinates well. I now have a bed of over two hundred of them.

G. grandis is, to my mind, a far more beautiful flower, with a far more elusive fragrance.

It is true that G. grandis can only boast two blooms on a spike, sometimes only one, but then they are as large as any of the gandavensis hybrids and far more delicate. The stems are about 3ft. high, and so fine that even the weight of the delicate blooms makes them bend over slightly. The colour of the flower is indescribable, sometimes brown, sometimes brownish-purple, with cream as a background, but the cream hardly shows at all, for the curious spots, stripes and mottlings of the darker shades.

Then there are two which seem to be very nearly related to G. grandis; these are tenellus and maculatus. The latter flowers on the lower mountain slopes in May. The blossoms are smaller than those of G. grandis and the flower opens in the daytime and is very sweetly scented. A couple of dozen of them in a vase will scent a large room. Like grandis, the flower is speckled with brown in irregular markings, generally a dark line down the centre of the petals.



THE SWEETLY-SCENTED GLADIOLUS MACULATUS

Then, in the very early spring comes another which seems nearly related, but with still smaller flowers, G. tenellus. The flowers are a rather lighter brown, and the whole plant is very dainty, but I do not think it is particularly fragrant.

Always every month of the year some species of gladiolus can be found in bloom. Even the small collection in my garden gives me at least one species in flower the whole year round. It is very interesting to watch with what regularity they appear. For instance, G. brevifolius will send up its spike the first week in April with the utmost regularity. There is nothing to mark the season; it is the fag-end of a hot, dry summer; everything is exhausted and just existing until the rains come. But G. brevifolius sends up its apology for a leaf, and in a week's time there is the dainty spike of brilliant pink bells with the loveliest golden markings on the lower petals. Afterwards it makes a long leaf and then dies down to await the closing days of another long, dry summer. But G. brevifolius is not sweet-scented; its glories should not be chronicled here.

G. recurvus is one of the most variable of our mountain gladioli and one of the most attractive; its blossoms may be coloured blue, pink, mauve, or the loveliest clear yellow, but they are always marked with gold on the lower perianth segments; and another distinguishing feature is the spotted spathe valve. Otherwise it is hard to distinguish from G. gracilis, which seems much the same but just several shades lighter and daintier, and the scent in this latter is not so pronounced. I cannot imagine a lovelier subject for the rock garden than G. gracilis. I am sure it would do well in a warm corner; given a little protection in the winter it would need no other care. In fact, the higher slopes of the mountains strike one as being perfect models for the planning of a rock garden, and among the heaths and proteas and aristeas these dainty gladioli are at their best.

To bring to a close the list of scented gladioli with which I am personally acquainted, I would mention G. alatus. The colour is a queer terra cotta red splashed on the lower segments with brilliant green, sometimes yellow, and the scent is exactly that of early summer apples in England. The whole plant is a little stiff and clumsy, being only about a foot high, but the large flowers and the sweet scent make it well worth growing. There may be other scented gladioli but I have not met them yet, and it seems to me we shall have a race lighter and daintier even than the newest primulinus hybrids when the hybridists have realised their possibilities, and when they have conquered the problem of scent we shall have the perfect flower. I had it pointed out to me that it is the gladiolus species with the least conspicuous colouring which are scented, and perhaps in this race of plants one cannot have both colour and scent. It may be so—but the colouring of G. grandis and G. recurvus is quite brilliant enough for my taste.

Growing Hydrangeas in Pots.

Treatment When Flowering is Over.

AS soon as the plants of hydrangea in pots go out of flower, the faded heads of bloom should be removed, together with a little piece of wood. In the case of specimens that are branching freely, a few of the other shoots may be shortened to render the plants more shapely. If the hydrangeas are placed in a cold frame, watered carefully and syringed lightly overhead during the afternoons of bright days, large numbers of young growths will soon be formed. Each of these, when it is a few inches long, may be pulled away and used as a cutting. These root very easily indeed if planted in sandy soil in well drained 3in. pots, one cutting being allowed to each pot. Shade and a moderately close atmosphere should be provided. In the late summer the plants must be given their flowering pots, which should be 5in. or 6in. in size. At this stage it is a good plan to have the plants out of doors in the sunniest position possible, and plenty of water will be required to encourage a free growth. Keep the plants in a cold frame during the winter, at which season most of the leaves will be shed. In the spring, new ones will be formed and the young plants will develop fine large flower heads if they are given a little heat from the middle of February onwards. By the method indicated it is quite easy to grow fine flowering specimens of H. hortensis and its varieties well within a twelvemonth.

WHEN PLACED IN POTS HYDRANGEAS MAKE EXCELLENT DECORATION.

As the plants go out of flower preparation should be made for increasing the stock for next year.

Make a Late Sowing of Annuals.

FOR filling vacant space, due, perhaps, to the failure of earlier sowings, and for maintaining a succession, hardy annuals of various kinds may be sown in June. Some will bloom in about six weeks from the date of sowing—the Virginian stock, for example—and all will be early enough to provide a display for many weeks later in the season. Among the most useful are: Annual gypsophilas, viscarias, candytuft, coreopsis, godetias, linarias, phacelias, saponarias and mignonette. The latter and night-scented stock are particularly valuable for growing in borders near the house or close to paths, as then their fragrance will be fully enjoyed. The spaces between newly planted herbaceous plants may be sown with annuals to give a finished appearance to the border during the summer; or they may be sown near early-flowering plants which, for the remainder of the season will be non-effective. It is essential for the welfare of the weaker growing perennials, as well as for the annuals, to avoid overcrowding, and thinning should be done before the seedlings are weakened through lack of space.

Staking Herbaceous Plants.

ONLY in isolated cases are these plants properly staked. By properly staked is meant being so supported that each specimen will retain its natural form without the supports being too conspicuous. One stake, judiciously placed, will be more effective than three that are badly placed. Usually, a large clump can be supported by the aid of three stakes or two branching sticks similar to pea sticks. The three are inserted near the outside edge of the clump, a strand of raffia is passed from one stake to the other just high enough to bear up the greater bulk of the clump when it nears the flowering stage; if the clump is extra large, two strands of the raffia may be passed, cross-wise, through the centre. When the plants are flowering neither the stakes nor the tying material will be visible. When only one stake is used there is the danger of tying up the clump to it in such a form that it resembles a sheaf of corn or a faggot of wood tied tightly in the centre. Yet this need not be. The single stake should be inserted at the rear and a litt'e to one side of the clump, not in the centre, and the strand of raffia should be passed loosely round the clump and again brought to the stake and tied. If a few small branching sticks are inserted near the centre of a clump at an early stage they will prevent the stems falling to one side.

Increasing Rock Plants.

THOUGH the rockery is still attractive, many plants are going over and fresh growth is appearing, which should serve as a reminder that provision will soon have to be made for future requirements. An easy way of raising numerous rock plants is by cuttings of the young growths stripped off with a "heel" or cut below a joint. A suitable length for the cuttings is about 2ins., and after removing the lower leaves, they may be inserted in pots, boxes or in a bed of sandy soil in a cold frame kept close. Where a frame is not available a handlight may be used with equal success. If only a few cuttings are required they may be struck in small pots and placed in others of larger size with a sheet of glass laid on the top. Shade till roots have formed and then admit air gradually till the plants are strong enough to stand full exposure. Keep the soil just moist till roots have been emitted and give water as required afterwards. When more space is required, plant out or pot singly as may be convenient. In the former case keep the soil frequently hoed and see that the plants do not lack moisture, especially after planting has been completed. Good specimens will then be available for transference to flowering quarters in autumn. Aubrietias, iberis, alyssum, saponaria, nepeta, alpine phlox, helianthemum, cerastium and lithospermum, are popular species which may be increased in this way. Old plants of straggling growth should be cut back after flowering to promote growths suitable for cuttings. The propagation of various kinds may be undertaken throughout the summer as cuttings become available.

Surplus Plants.

THERE is often a number of plants left over when beds and borders have been filled and requirements have been met in respect of pot plants for greenhouse decoration Fuchsias, ivy-leaved and zonal pelargoniums, heliotropes, nemesias, antirrhinums, asters and petunias are some of the most accommodating and popular subjects for growing in window boxes and hanging baskets, and surplus plants of these, even though they be a little inferior to those selected for the beds and borders, will prove equally effective in due course, and add much to the exterior of the house, besides affording pleasure when viewed from the inside. A veranda offers an opportunity for the display of basket plants, for which, among others, ivy-leaved pelargoniums and petunias are adapted

On Weeding and Thinning.

LOSE no time in beginning to weed and thin crops of vegetables, hardy annuals, etc. Early thinning is always an advantage, in a double sense, for the crops benefit and the work can be done much more quickly than when left till a later stage.

Some vegetables, like carrots, onions and leeks, are best thinned while the soil is moist, but turnips, lettuce, beet, etc., may be thinned when the soil is quite dry. During dry weather the more frequently the hoe is plied the better for conserving the soil moisture and for getting rid of weeds. All crops respond to a good stirring of the surface soil.

If it is necessary to thin and transplant vegetables like leeks, cabbages, etc., during a spell of dry weather, give the plots a good soaking of water the previous evening. Newly planted stuff should also be given a good soaking and if the sun is strong, shading with leafy twigs and branches may be necessary until the plants take root.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Half-Hardy Vegetables for Present Sowing.

A FEW of our garden vegetables are too tender to be planted before May. Often we hear of kidney beans being "blighted" by frost, all because they have been sown too soon. At the present time French beans, runner beans and marrows can fairly safely be grown out of doors. Only in exceptional seasons do we get frosts late in May.

Runner Beans.—There is no better vegetable for all round cultivation than the scarlet runner bean. It is equally at home on the allotment and in the back garden. In Walworth—the geographical centre of London—I have grown them alongside an ugly wall with great success. Not only were they a feast of colour, but they furnished a plentiful supply of luscious beans for the table. Like all the legumes, the runner bean is a gross feeder and needs a liberal supply of manure to produce good beans. Beans and peas do not need so much nitrogenous manure, as their root nodules have the power to utilise the nitrogen of the air. But they do need plentiful supplies of potash and phosphates. A good fertiliser would be 3oz. of superphosphate of lime and 1oz. of potassium sulphate applied to every square yard. This should be in addition to a dressing of organic manure.

Beans in Rows.—Runner beans are best planted in rows. The easiest way to do this is to take out a trench a spade in width and depth, mix in manure at the bottom and cover to within 2ins. of the surface with soil. Sow the seeds in a double row, 6ins. apart, each way, and cover with 2ins. of fine soil.

Staking Beans.—It is advisable to stake the beans at once, as they soon become entwined together if left after they germinate. Bean poles—stakes about 8ft. long, are the best supports—but poles with wire or string stretched between will suffice. Dust the seedlings with lime and soot to keep away the slugs and other pests. During spells of dry weather syringe the plants well with water to keep away red spider—a pest which attacks the undersides of the leaves, causing them to turn yellow. Also, water freely, or the flowers will drop. Beans should be kept picked, as seeds which are allowed to remain check the further development of the plant. A pint of seed should sow a 35ft. row. Best of All, White Czar and Painted Lady, are good varieties to grow.

French Beans.—French Beans are not so prolific as runner beans, but are preferred by many on account of their tenderness. They are sown in drills 3ins. deep and 18ins. apart, allowing 9ins. between the plants in the rows, and give an occasional dressing of Kainit and superphosphate. Gather the beans when young, or they will not be tender.

Vegetable Marrows.—Sow seeds of vegetable marrow out of doors, under a sheet of glass. Three arranged triangle fashion are enough for a clump, and they are best sown where they are to grow. A barrowload of manure, in a big square hole, covered with 6ins. of rich soil, is the best marrow bed. Water copiously in the dry weather. Young plants of vegetable marrows which are ready for transplanting can be put out now into the open, if a sheet of glass can be put over them on cold nights. The site must have plenty of manure under it, and an old custom is to make the marrow bed on the top of a heap of manure, or where a hot-bed has stood. Large White, Large Green, Table Dainty and White Bush are reliable varieties.

Ridge Cucumbers.—These are a hardy variety of cucumber, quite suitable for cultivation out of doors. Rich soil, 1ft. deep, formed into a rounded ridge 3ft. wide, will do for cucumbers. Plant on the top of the ridge and protect young plants at night. Prolific Ridge and Long Prickly are useful varieties for outdoor culture.

Beetroot.—Beet, both globe and long varieties, are another tender vegetable, seeds of which can now be sown. Draw drills 2ins. deep and 15ins. apart, finally thinning the seedlings to 9ins. apart in the rows. Globe and Dell's Crimson are reliable kinds.

After the Bulbs.

SPRING-FLOWERING bulbs have been particularly fine this year. Long days of sunshine added substance and colour to the blooms. As soon as the leaves turn yellow, the bulbs can be lifted and dried off to make way for summer flowers. In a tiny garden, it is a problem how to do this effectively. In a bed such as that illustrated, the summer bedding plants could be planted between the bulbs, thus allowing them to ripen off without disturbance. Daffodils can be allowed to remain permanently in the ground, if desired, but tulips are best lifted and stored after the tops have withered.

SUMMER BEDDING PLANTS MAY BE PLANTED BETWEEN THE BULBS WHICH HAVE NOW WITHERED OFF.

Summer Stimulants.

PLANTS grow very rapidly during the warm summer days and, like growing children, they need extra nourishment to keep them strong and healthy. Liquid manure is especially valuable, because its action is quick, and it is easy to apply. Artificials of a soluble nature can be purchased ready for use, but if any form of animal manure is available, a very good stimulant can be made with little trouble. The usual quantities recommended are as follows: 2½lb. of cow dung to a gallon of water, or a pint of poultry droppings or sheep droppings to two and a half gallons of water. Soot water is also a useful stimulant.

For ease in making and using, nearly fill a rain barrel with water. Fill an old sack or cotton bag with the manure and suspend it in the water. Allow this to remain for a few days before use, and as the liquid is taken away, fill the barrel again, to keep a constant supply. Use the liquid in a sufficiently diluted state to be of a pale straw colour. It is best applied when the soil is wet. Border or pot chrysanthemums, dahlias and tomatoes benefit from applications at fortnightly intervals.

A Town Hobby.

Growing Succulents.

THE quaint and occasionally beautiful growths of various succulents have many admirers among town dwellers. They appeal specially to those who have very limited space in which to grow plants, for many of them can be grown in tiny thumb pots, of which several dozens could be accommodated in any small case.

The flowers of these curious plants are often very brilliant and showy, though the plants themselves are more quaint than graceful. Few can stand a very low temperature, probably on account of the moisture stored in them, which would naturally be more affected by frost than a dry woody structure. Most of them must be kept at a temperature not less than 40° during the winter, but as they are quite at home in a dry atmosphere in winter, a warm room is perfectly suitable for them. Much variety and beauty can be obtained from their cultivation. There are many species of cactus in cultivation. The mammillaria section are most suitable for limited space.

Spring and summer are the times when repotting may be done. Silver sand and brick dust should be used in preparing the compost, and most of the old soil, and any faulty roots, should be removed before the repotting is done. More water and a moist atmosphere are needed during summer, when growth is taking place.

Work Among the Vegetables.

PINCH out the tops from the broad beans that are now in flower. This prevents the appearance of black fly. Potatoes need earthing up, otherwise the exposure of the tubers to sunlight may make them turn green, which gives them a disagreeable flavour. A Canterbury hoe is the best tool to use and a few minutes spent in drawing up the soil against the stems will prevent much disappointment at the dinner table.

What to Do with Weeds.

THE disposal of weeds and grass clippings always presents a problem, particularly in the small garden. I make a practice of burying weeds as soon as they are collected, and also new mown grass clippings. In a larger garden one can have a sunk pit, into which the weeds, etc., are put, with a layer of soil over them now and again. The pit becomes a valuable source of manure to use when winter digging is done.

Climbing French Beans.

IT may not be known to everyone that the dwarf French bean can be obtained in climbing varieties. The beans are exactly the same in flavour as the dwarf kinds, but they carry a heavier crop. They give quite a good yield before scarlet runners are ready, and continue to produce pods over a long period. A good variety is the Climbing Canadian Wonder, which is like the dwarf bean of that name.

NOTES ON THE FLOWER GARDEN

Grow Snow in Summer.

SNOW IN SUMMER (cerastium) is a plant which spreads very quickly in rich garden soil, but growers are agreed that the billows of white blossom produced in summer are delightfully decorative and decidedly attractive. Left untended, however, a small plant soon becomes a large clump, inclined to choke everything near it, and even the profusion of white flowers cannot atone for loss of other plants. Grown in a poor soil or where root moisture is not too abundant in summer, as, for example, on a dry wall or high up on a rockery, the plant is much less profuse, although equally floriferous; intending growers can remember this and act accordingly. In all cases cut the clump back almost to soil level when the flowers fade; it will, thereafter, produce a compact mass of foliage and bloom satisfactorily next year without being able to assume a dangerous size. The two points which make this delightful plant a pleasure and not an annoyance are, then, a poor site and clipping after flowering.—LANARKSHIRE.

How to Increase your Stock of Hardy Primulas.

Now is the time to divide the plants that have finished flowering.

THE time has arrived when it is necessary to divide such of the hardy primulas as have ceased flowering, together with primrose hybrids and polyanthuses. June is a good month for the work to be done, and there is nothing gained in postponing it, as young plants give finer flowers and are more satisfactory in the long run. Whatever may have been the position they occupied in spring, one thing is quite certain, and that is, their summer quarters must be one where they can enjoy both coolness and shade.

Primulas, like rosea grandiflora and involucrata are never better served than when they can be planted in as moist a position as the garden affords. Others, like Juliæ, that gem of miniature growth, with flowers of crimson purple, and the wine-coloured Wanda, both most serviceable for the rock garden, are most productive, a dozen-year old plants in my own garden of the latter having split up into five dozen plants. Surely a good investment when one bears in mind that it bloomed from the middle of February to the end of April out in the open, needing not the slightest protection. Polyanthuses, too, are so quick in growth as to necessitate yearly division if one is to keep up the quality of the flowers.

Methods of Division.

A good way, after lifting each clump, is to shake away the soil, and thrust between the roots a hand fork, working carefully between until severance is made, or one can often pull them apart with fingers and thumb. Every little bit with a vestige of a root will soon take hold if planted in good soil. They should be put out 6ins. apart in well dug ground in which has been incorporated leaf-mould or old leaves and road scrapings and a little decayed manure. Firm planting should be the rule. Position is most important. A shady spot on the north side of the garden or alongside a row of runner beans or tall peas, or any place known to be damp will suit them. A dry, sunny quarter is the worst, as invariably as the summer advances they become limp and are apt to dwindle away. Should the weather be dry at the time of planting out, one or two soakings of water will generally ensure their getting hold.—CLAREMONT.

Sow Perennial Gypsophilas Now.

Raising New Plants from Seed.

OWING to the long fleshy roots of perennial forms of gypsophila, increasing the plants by attempting to divide them is never very satisfactory, and, in fact, with several-year-old plants it is well-nigh impossible to obtain good results.

It is known by all who grow them that it is unwise to interfere with plants once they have become established and doing well. If more plants are wanted, they can be raised from seed which can be sown any time during May and June in pans or boxes of light soil in a cold frame, pricking off the seedlings into a nursery bed subsequently and, finally, into permanent quarters, which should be in a place where the sun can reach them, allowing 3ft. or 4ft. between them and other plants. If the soil is known to be deficient in lime, then at the time of planting some lime rubble or old mortar should be worked in, digging the spot they are to occupy 2ft. or even 3ft. deep, as they are "delvers." Once put in their final position, they should not be meddled with, as it is almost impossible to lift an established plant without breaking the roots. Another method of increasing a stock of gypsophilas is from cuttings, and the little shoots which appear on the sides of the stems will in August be sufficiently ripe for pulling off. This I find is better than cutting, as if they can be pulled at a joint and inserted around pots of soil made up of loam, leaf-mould and some sharp silver sand, kept close to the glass in a cold frame, but shaded from sun for a time, they will by the following spring be ready for planting out where they are wanted in the garden. I have seen so many failures with gypsophilas being removed after they have become established that it is well to emphasise the importance of giving them a place in the sunny part of the garden where no shifting will be required. "Leave well alone" is an old adage which is applicable to this popular hardy perennial.—W. L. L.

SNOW IN SUMMER MAKES A DAZZLING SHOW IF PLANTED ON DRY ROCKERY BANKS.

Here it looks particularly well flanking a house approach which was formerly a rough, unsightly, stony bank. It is an easy plant to cultivate and one that every amateur should grow.

Hardy Flowering Plants in Dry Soils.

The Benefit of Hoeing and Mulching.

SOME hardy-flowering plants make little progress when planted in soil that is dry and sandy, and in a hot season give results that are not satisfactory. We cannot choose soil, but have to make the best of what we have. We may, however, do much towards making plants more vigorous by a judicious use of the hoe—and I use the word judicious advisedly—as it is not suggested one should ply that most useful implement too near the roots, but to stir the soil in such a manner in the borders to admit air, enable rain to reach the roots and generally promote growth. When hoeing has been done, a mulch of old manure about the roots of hardy plants will be found advantageous, as it will keep them cool and in hot weather does much towards conserving moisture. It is particularly helpful in the case of phloxes, rudbeckias, peonies, campanulas, anthemises, starworts, helianthuses, achilleas and heleniums, all of which begin to show signs of failure in a time of protracted drought should the soil be poor and dry and no mulch be given. Some people have an objection to mulchings about a garden in summer, as it makes for unsightliness, but this can be got over by spreading a coating of soil over the manure if need be. It is better to mulch and have flowers worth cutting than not to do so and see the plants pine away. The present is a suitable time to give attention in the way suggested to hardy plants in soils known to be dry and poor.—W. F.

Summer Rose Pests.

IT is hardly possible to escape attacks of aphides or green flies in our close, confined gardens, but, fortunately, they succumb readily to soapy water, 2 oz. of any kind of soap per gallon. I, personally, prefer to apply this tepid and to use a disinfectant soft soap. Leaf-eating caterpillars, when they cannot be hand-picked, are poisoned by means of arsenate of lead, the application of which at 1 oz. per gallon effectively coats the foliage with an invisible film of poison. Nicotine is also very good for the purpose, perhaps even more effective when the pests roll up the leaves and hide inside. The homely paraffin emulsion must be relegated to the fruit border, although in the old days we thought it fine—but it smells. Chafers and bud-gnawing insects disappear when any spray is applied. Although readers may imagine a "chemist's shelf" as a necessary adjunct to the rose border, I hasten to remove that impression. The scientist first knows his pest, then gets the correct cure; but the application of one insecticide generally removes all pests, although it may not just be the best for all purposes. Indeed, I go farther and state that the tepid soap solution first mentioned, used occasionally to clean the foliage and clear away odd pests, ensures quite clean bushes with little expense and trouble. It, or a proprietary insecticide somewhat similar, applied now and again repays the grower over and over again.—L.

Chrysanthemum Pests.

UNDOUBTEDLY the most insidious pest of the chrysanthemum is the leaf-mining grub, which disfigures the foliage, produces partial defoliation at times and cripples the plants much more than many growers believe. Individual grubs may be killed by pinching the leaf between finger and thumb, but as soon as one or two pests are seen begin spraying the plants at intervals to keep away the parent flies which deposit the eggs. Plants under cover should be fumigated with "Auto-shreds" or other efficient "gas." Earwigs haunt some gardens and do much damage by gnawing at the

Digitized by Google

succulent tips of shoots. A bad attack is, of course, a calamity, but if the plants are again sprayed and if traps (inverted pots with paper or moss, hollow flower-stalks, etc.) are made use of, the danger is quickly removed. Aphides and black fly are sure to go equally quickly if an insecticide of some kind is applied. I like the nicotine washes best in this case, but, let me admit, there are many fine washes of high efficiency. The old plan was to dust with tobacco powder, which can still be obtained in shilling tins. Dust it on in the early morning. I am a firm believer in the application of an insecticide at intervals as an insurance against trouble. Select some wash and apply it now and again for prevention; this is invariably better than cure.—H. H. A.

Wallflowers from Cuttings.

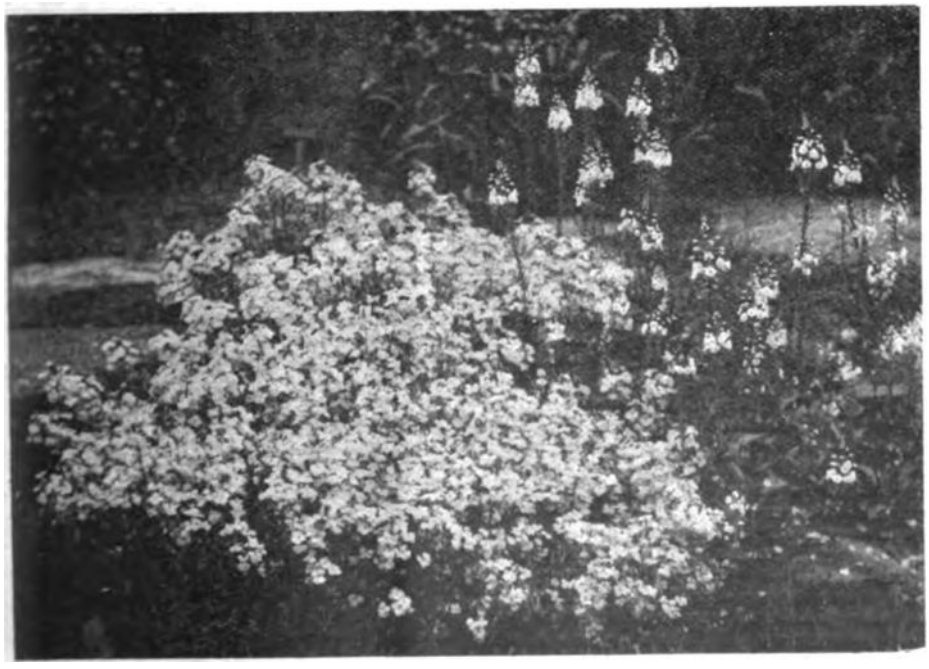
UNDER this heading will be found a charming series of wallflowers, suitable for clumps on the rock garden, or for producing a display in the ordinary flower border and in most cases they are increased by means of cuttings. One that always gives a good account of itself is Cheiranthus Harpur Crewe, a neat little old-world wallflower which of late years has more or less dropped out of cultivation. When its merits are known to the present generation of gardeners, I feel sure this delightful plant will be restored to its proper place. It attains a height of 12ins to 15ins., and its refined spikes of richest golden yellow double flowers are freely produced; while they are sweetly fragrant, reminding one of mignonette. It is easily grown, and there is no difficulty in keeping up a healthy stock. Flowering at the same time, *viz.*, in April and May, is a hybrid known as C. Newark Park, the single flowers being a fine coppery orange. In a clump 2ft. or 3ft. square it is most effective, and should be represented in every garden. With me it grows about 9ins. high. A closely allied hybrid is C. Marshalli, with orange-coloured flowers. C. Pamela Pershouse is a more recent hybrid between C. Allionii and C. alpinus. The flower characters are those of the former parent much improved, the colour being even a richer orange. It forms a bushy plant a foot high, quite hardy and perennial, but it pays to keep the stock young and vigorous by taking cuttings occasionally. This is a decided acquisition among early-flowering plants, and is suitable both for the rock garden and border. A lovely plant for the rock garden is C. alpinus, a Scandinavian species with clear light yellow flowers; while C. mutabilis, a native of Madeira, produces bronze and yellow flowers. In pleasing contrast to the above is C. Lemon Queen; this has been very effective in close proximity to its more showy brethren, but a few plants will be enough for most people. Nevertheless, some will like it on account of its peculiar shade of lemon yellow. A charming little plant which is best raised from seed is C. linifolius, sometimes quoted as Erysimum linifolius. It is excellent for old walls, and is a Spanish species with cool lilac flowers. The finest results are obtained by sowing the seeds where the plants are intended to bloom.

Directly the flowering period is over, the plants are neatly trimmed, and in the course of a few weeks a number of basal shoots will appear which are most suitable for cuttings, if they are procured when they are 2ins. or 3ins. in length.

These readily form roots if placed in sandy soil and kept shaded for a week or two from the direct rays of the sun. A cold frame or hand light will be found useful for rooting cuttings, but a sheltered corner of the garden where a little shade can be afforded is also suitable. If only a few plants are required, they can be arranged in small flower pots and plunged in ashes or soil; but for larger quantities it is better to dispense with the pots, and set the cuttings directly in the frame.

A light sprinkling of water is needed daily if the weather is fine, and when roots have formed the plants should be fully exposed. At the first opportunity they can be transferred to their flowering quarters.—B.

A COLONY OF THE BLUE-FLOWERED OMPHALODES CAPPODOCICA FLOURISHING IN A ROCKERY.



THE LEMON-YELLOW CHEIRANTHUS ALPINUS, A FINE WALLFLOWER FOR THE ROCK GARDEN.

A Free Flowering Navel-Wort.

THE omphalodes constitute a small genus of hardy and beautiful plants, all of which can be raised from seeds and the majority increased by division.

O. verna, the Blue-eyed Mary, is well known on account of its turquoise blue flowers, but I desire to call attention to another fine member of the family, *viz.*, O. cappadocica. In its native home it grows in shaded places, and in this country it has proved a success in a variety of positions and soils. No doubt the finest effect is produced in partial shade, since the beautiful deep blue flowers are more intense in colour than when exposed to full sunshine. The illustration depicts a colony of this charming plant growing in the rock garden at Castleford, Chepstow, a neighbouring elm tree affording that essential bit of shade when the sun is at its highest. The habit of the plant and its free flowering qualities can readily be seen, but a mere photograph cannot do justice to the beauty and colour of the flowers. These are produced in April and May, in graceful loose sprays about 6ins. high. O. cappadocica will thrive in any well drained loam, and where the soil is rather heavy it can be rendered suitable by adding leaf-mould and grit.

This plant can be increased by division during the early autumn, but it is readily raised from seeds which should be sown at the present time in pans or boxes of light soil. Cover the pans with paper or a sheet of glass until the seedlings appear, and when large enough transplant a few inches apart.—T. W. BRISCOE.

MAKING A HARD TENNIS COURT

FROM the purely horticultural standpoint the hard tennis court has nothing to recommend it, and one can quite appreciate the points of view of the seedsman who specialises is grass seeds, the garden contractor who lays turf lawns, and the gardener who considers a hard court a disfigurement to the garden.

The degree of satisfaction derivable from a hard tennis court depends upon the quality of the court, or, in other words, upon its construction and maintenance, and whereas there appears to be a general, vague sort of assumption that he who makes and manages a grass lawn can also, and with every satisfaction, make and manage a lawn tennis court, there is a deal of difference between the two, and for the peace of mind of all concerned it is well that the vital points of difference shall be clearly understood.

If care is taken in the choice of a site for the court and consideration given to the construction and planting up of the surrounding banks, even a hard tennis court can be made most attractive. In the accompanying illustration is shown a hard tennis court in a reader's garden, around which has been built a splendid rockery bank. Surrounding the court is a stone and earth wall, 7ft. in height at the top and planted up with rock plants in variety, including arabis, aubrietias, thyme, alyssum, saponaria and cistus. The presence of the rockery and the blaze of colour presented by its varieties in spring and early summer has rendered this part of the garden most attractive.

A HARD TENNIS COURT IN A CORNER OF A READER'S GARDEN.

The rockery bank planted up with clumps of rock plants enhances the appearance of the court.

Too many have imagined that because a hard tennis court is constructed of rubble and porous material of various grades, it is of small importance what may be the character and condition of the earth-base upon which the court is built, but that is an error which has been responsible for many disappointing failures. The base is not one whit less important to the hard court than to a grass court or bowling-green.

The principal consideration is drainage, but solidity and firmness are also important matters; a loose, shifting sand or spongy, vegetable soil, even though free from troubles arising from stagnant water, may prove to be a source of perpetual anxiety, and it is quite possible that excessive dryness may be as detrimental as excessive moisture. Methods of opening up a retentive, soapy clay soil are too frequently described to require reiteration here, but there are spongy soils which require the solidifying assistance of shingle, ashes or gravel, and loose sands should have a liberal dressing of binding material in order to provide a base into which the bottom layer of foundation clinkers or stones will not easily sink.

The edges of a hard court are of much importance. Wood is quite unsuitable and, indeed, no long, narrow strips which are simply held in position by pegs or stakes driven in the ground can be permanently satisfactory. Brick margins, properly laid in cement, are the best, and, in the long run, most economical, and time should be allowed for the edging to 'set" thoroughly firm before further work proceeds.

Of all material for base work nothing is more satisfactory than coal or coke clinkers. These should be graded in three or four grades, the largest ranging from 3ins. to 4ins. diameter to about 6ins. or 7ins. Over these should come a layer ranging from about the size of hens' eggs to that of walnuts, and over this layer another consisting of dust-free pieces about the size of cherries and hazel nuts.

The proportionate thickness of these layers may be varied somewhat according to the nature of the ground beneath; the lighter and more porous the base the more of the larger clinkers to be used, while on a soil that is inclined to be constantly damp, the middle layer may, with advantage, be several inches thicker. Over the whole sufficient breeze or ashes should be spread to finish off with a smooth surface.

It would be bold to declare flatly that any one material at present in use is the finality of perfection for hard court construction, and while it is perfectly natural for makers to maintain that their materials and workmanship ensure the very best court obtainable, unbiassed opinion will acknowledge the existence of a number of quite good types or kinds, and will still venture to surmise that still further developments and improvements are near at hand.

The familiar brick-red courts have many points in their favour, among which porosity and elasticity are, perhaps, the most important, and of disadvantages the worst is colour, and in some cases there is also a certain amount of adhesion to balls, shoes and flannels.

A clay-coloured court made by Messrs. Bakers, Codsall, is less glaring and less tiring to the eyes than the brick-red, and for play it is highly satisfactory, the strongest criticism I have heard of this court being that it looks like playing on bare earth. The important point is that the player quickly realises the difference when the court is put to the test.

The grey court made by Messrs. W. Wood and Sons, Limited, Taplow, is an excellent court when aged. Its elasticity is good, it stands wear remarkably well, and involves little labour in maintenance; the two blemishes which it would be worth white to remove are the painful gleam and obnoxious odour of the quite new court.

Visitors to Chelsea would notice various types of modern hard courts, green in colour, requiring no attention or upkeep, and unaffected by frost or rain. Many firms specialise in these new types of courts and we advise the reader to obtain catalogues and select one after a perusal of these brochures.

Experiments have been afoot for some few years in the direction of securing a lasting green of restful tint with which the various materials in use may be coloured. The right green is, in fact, obtainable, but, unfortunately, it is costly. Concrete mixtures of various kinds have been tried, and such materials as asphalt, tar and ashes have figured in courts of a more or less experimental character. but it is no easy matter to overcome such difficulties as lack of elasticity, tendency to fatigue the player unduly, prevention of cracking and the satisfactory disposal of surface water.

Amateurs who have sought and secured materials closely resembling the surfacing of courts made by well known experts have frequently erred in important details. One vital point is that most, if not all, kinds require to be laid in layers, each layer screened to a particular size, for it is only a final, usually quite thin layer that is extremely small, and as a rule this final layer is treated by some more or less secret process to make it clean, moderately binding and as nearly dust-free as possible. All things considered, efforts to economise should extend no farther than construction of the brick margin and clinker foundation, the surfacing being contracted to one or other of the reliable experts, who should be asked to inspect and approve the foundations before finishing off the court.

Be advised, when about it, to make a proper, full-sized court; the small saving in cost of a "cramped" court will inevitably bring regrets and discontent.

The measurement of the court itself should be 78ft. by 36ft. By allowing a total length of 120ft. and a breadth of 60ft., a "run back" of 21ft. is provided at each end of the court, with a 12ft. margin on either side, not at all too much for the fast play which is customary on hard courts. Water should be laid on, and a hose with a widespread fine rose is required for soaking without dislodging the surface. The best "sweeper" is a breadth of hard carpet hemmed at the lower edge to take a flat iron bar to weight it down. Straps should be fixed to the top corners, and by drawing this behind him a lad may smooth the whole area in half an hour, and this should be a daily task. Rolling will be necessary with changing weather, but the roller should be a big, hollow, unweighted, double cylinder roller.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

ALTHOUGH a succession of dry sunny days was experienced during the last week in May, the temperature was kept low for the season of the year by the prevalence of north-east winds, the effect of which was more particularly felt at night and in early morning, when there was a decided nip in the air. In the opinion of certain weather experts, general summery conditions are out of the question until there is a steady rainfall and the wind has changed to a more favourable airt. This is a consummation greatly to be desired in the interests of gardeners, for much work has still to be done in gardens in the form of planting out summer-flowering subjects in bed and border.

Dahlias can now be transferred to their permanent quarters quite safely, and those readers who are in the unfortunate position of having to purchase their stock of chrysanthemums should do so without further delay, as there is a scarcity of plants and several nurserymen are already sold out and are under the necessity of buying in popular varieties for the purpose of fulfilling orders.

To the amateur whose ambition is to make the most of the limited space at his disposal, the growing of flowers and shrubs in tubs or boxes suggests numerous possibilities in outdoor decoration. It is a fascinating form of gardening, suitable alike for the town residence or the country dwelling, and there are few situations which would not be improved by the introduction of that simple method of floral culture. Tubs placed on either side of a front or back entrance make an effective display; outside stairs connected with house or garden may also be used to good purpose, but perhaps the maximum of usefulness is to be found in the back courts of tenement houses, where a few hardy flowering subjects provide a pretty bit of colour that helps to dispel the drab and depressing outlook. Wherever placed, the charm of these receptacles in summer will always be felt, and their influence on old and young cannot be otherwise than helpful in encouraging a love for the beautiful in nature.

Small margarine or lard tubs and boxes are quite suitable for the purposes mentioned, and these may be had from a grocery store or butter shop for a few coppers. To provide the necessary drainage, holes require to be bored in the bottom of each wooden receptacle; and a coat of green paint greatly improves the outward appearance. In cities or large towns a suitable compost is generally obtainable at any of the public parks, while the more fortunate householder who has the ingredients at his disposal may proceed on the lines of the following formula, *viz.*, fibrous loam 2 parts, flaky leaf-mould and well decayed manure 1 part each, to which may be added a handful of coarse sand to each tub. In making a choice of plants, the position to be occupied must be considered, for it would be courting disaster to place subjects of a tall-growing habit in an exposed situation.

I have frequently seen fine specimens of Campanula pyramidalis grown in tubs in a sunny sheltered position, and for an entrance hall or veranda they are quite suitable. Hydrangeas do well in tubs and provide a nice bit of colour over a long period, but for general usefulness there are no plants that can excel funkia and kochia, as they thrive in any situation. The former has variegated or green leaves of decorative merit; while the latter is a hardy annual with fern-like foliage which changes in colour from soft green in summer to red in autumn. Other favourites which usually succeed under this particular treatment are Canterbury bells and azaleas (for early summer display), larkspurs, geraniums, calceolarias, marguerites and the dwarf Dahlia Coltness Gem.

The Glasgow and West of Scotland Horticultural Society, having been deprived of the use of the Kelvin Hall for the third year in succession, have arranged to hold a two days show in St. Andrew's Halls, on September 7th and 8th. It was a case of Hobson's choice, and to suit the limited space a number of classes in each section had to be deleted for the time being. The schedule in its abridged form is quite attractive, and consists of 240 classes apart from the allotment holders' exhibits. ST. MUNGO.

WHAT OUR READERS SAY

AN OLD ESPALIER APPLE TREE.

SIR,—I am enclosing a photograph of a long espalier apple tree which is growing in the garden at Meriden Hall. This tree is 64ft. long and has a butt of 6½ft. It is over a hundred years old and still bears frequently. The fruit is an attractive green colour and is excellent when cooked.—J. BEDHALL, *Meriden*.

A FINE ESPALIER TREE SIXTY-FOUR FEET LONG AND OVER A HUNDRED YEARS OLD.

A DAFFODIL CLASSIFICATION.

SIR,—The Editorial for May 7th contains some interesting remarks on daffodil classification. I imagine that the prime obstacle in classifying is an unwillingness on the part of conscientious classifiers to deny to about two-thirds of all the existing named varieties of daffodil the right to be considered varieties at all. At present, for example, there are a score or more of improved King Alfreds or slightly more robust van Waveren's Giants when only one—the first in the field—is entitled to be considered a distinct variety. Another and still more knotty point is the right of a variety to be so considered which attains a handsome stature and distinct individuality under most favourable conditions, but when not accorded treatment wholly to its liking promptly assumes the appearance and proportions of one of the commoner varieties. I may mention as a typical offender in this respect Weardale Perfection, which only attains perfection when pampered with all the nurseryman's arts.

This raises another point. One of the essential reasons why a new daffodil classification is required is that at present the purchaser of daffodil bulbs has no knowledge as to the sort of treatment they require, but in the absence of generally painful experience takes the salesman's assurance that any daffodil will thrive anywhere, tempering this assumption with the common-sense proviso that the more he pays for a bulb the more likely it is, for some unknown reason, to "die on him."

How many know, for example, that King Alfred simply will not grow in wet, clayey soil, while the Tenby daffodil (N. obvallaris) revels in it? Curiously, I have examined the dealers' lists carefully and can find no instance of a new variety being recommended because of its suitability to some particular class of soil, climate or position.

These things would not be so difficult to discover if there existed a classification based not merely on arbitrary divisions—colour or length of trumpet—but on the species or old-established varieties (some of which are almost constant enough to attain specific rank) from which they derive. It may be suggested that the strains are too mixed, that the crossings and recrossings have been too greatly multiplied to allow of this. I am inclined to doubt it. You cannot name all the ancestors of, say, Sergeant Murphy, but you can see that the maximus strain predominates in it just as you can see in Mme. de Graaf distinct traces of moschatus.

I agree that in its earlier stages such a classification would be based on somewhat fragmentary data, but more data would be forthcoming as time proceeded. I doubt whether many of the existing varieties of daffodil are constant. What is wanted is that a certain number of selected varieties should be chosen now, that they should be

Digitized by Google

planted in "natural" conditions and left to multiply. At the end of perhaps thirty years—or it might be sooner—a classification of their varied and numerous offspring (strictly offsets and not, of course, seedlings) could be made. Theoretically, then, their progress back to the ancestral types should produce all the intermediate varieties which, as your Editorial points out, have at one time or another been listed but are now lost. It may be that it would take, not thirty, but a hundred years for this retrogressive horticulture to produce interesting results. Even so, it is worth undertaking.—C. H. BRETHERTON, *Oxford.*

SPRAYS AND THEIR USES.

Bordeaux Mixture.

SIR,—I was interested in "H. B.'s" article on "Sprays and Their Uses," in the issue for May 21st. I should, if I may trespass on your space to such an extent, like to add my experience in the matter of using Bordeaux mixture and allied fungicides, more especially in the control of scab on apples and pears.

In the first place, I must emphasise the great importance of pre-blossom spraying of apples to control scab. Just as the flower buds are showing their pink petals is the best time to spray for the first time. This should be followed by a second application immediately the petals fall and, if necessary, again three weeks later. Perhaps the words "if necessary" will puzzle some amateurs, so I think a word or two dealing with the disease itself may not be out of place.

I do not intend to deal with the life history of the fungus, but will just say that it first shows itself on the leaves in spring, in the form of dark green or black patches on the leaves. It is mainly from these infected leaves that the fruit is attacked, so that if we can keep the disease in check early in the season, clean fruit may be expected.

Now, as to the use of the different fungicides. Bordeaux mixture is, perhaps, the best known and the most popular, but I have had much leaf scorch through using the normal 4—4—40 recipe. A great advance on normal Bordeaux mixture is what is now known as excess lime Bordeaux mixture. This wash, while as active a fungicide, does far less harm in the form of leaf-scorch than the normal mixture—in fact, I have not found any harmful effects from applying it. I have just sprayed an acre of apples with this mixture.

In preparing excess lime Bordeaux mixture the following materials are necessary: 12½lb. of quicklime (preferably white Buxton lime), 4lb. of copper sulphate and 50 gallons of water. To prepare the mixture, add just sufficient water to the quicklime to slake it and then make up to a milky fluid, which should then be strained into a wooden vessel containing the rest of the water and the copper sulphate. Before taking any of the liquid from the tub, stir thoroughly and always keep the fluid agitated while being used, as the lime and copper sulphate are not dissolved in the water but merely suspended, and will, if allowed to stand only half an hour, settle somewhat.

One other precaution about using this mixture: Only make up sufficient for one day, as this Bordeaux mixture when more than one day old is not safe to use.

The other fungicide commonly used is lime sulphur. This is a powerful wash and can do considerable damage in careless hands. Its great advantage is that it can be bought—and is, in fact, best bought—ready made. The strength of lime-sulphur to use for summer—or perhaps I had better say spring—spraying is 1 part in 30 parts of water, except for tender-leaved varieties, such as Cox's Orange Pippin, James Grieve and Newton Wonder, in which case 1 in 60 is plenty strong enough. A little leaf-scorching may occur after using lime sulphur, but, if carefully used, not enough to cause anxiety.

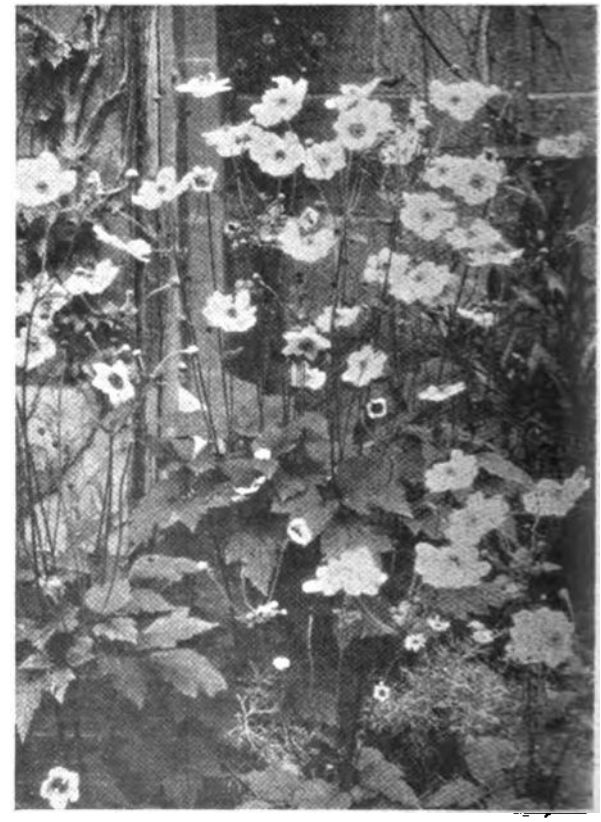
You will notice that I emphasise *spring* spraying above, and when writing that I had in mind a tree of Potts' Seedling which I sprayed experimentally with lime sulphur at a strength of 1 in 100 two years ago, in late June. The result was appalling. The tree dropped all its fruit and most of its leaves. I mention the last item simply to warn amateurs against indiscriminate use of washes at other times than those advised.—N. D. H.

OUR PHOTOGRAPHIC COMPETITION

Our weekly photographic competition is embarrassingly successful. In the present issue, in addition to the "award" photographs, we publish on other pages a number of interesting pictures which have been sent by competitors who clearly possess a sense of what will be interesting to their fellow gardeners as well as showing that they can use their cameras with judgment and skill. As announced last week, we shall continue to publish photographs on other pages, apart from the actual competition. Some afford opportunity to us to enlarge on our competitors' notes and suggestions, as they have done elsewhere in this issue. Readers who do not see their photographs immediately must not conclude that they have been unsuccessful, for we shall draw on our accumulated stock in awarding prizes week by week. But do not let it be supposed that we wish readers to cease taking and sending in photographs. Opportunity for taking them passes all too rapidly.

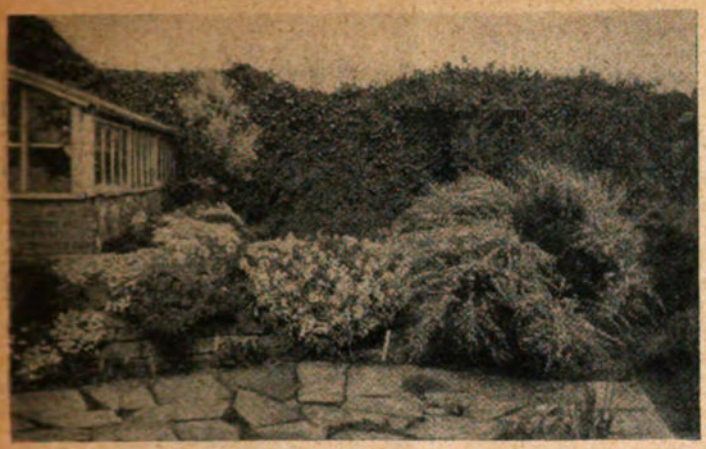
The Madonna lily is one of the most charming of garden flowers. In my garden, this clump is growing in a bed along with delphiniums, irises and pinks, and the combination is most attractive. The soil in which they are growing is a rich heavy loam and the bulbs were only planted some 2ins. to 3ins. deep. I carry out regular spraying with Bordeaux mixture if lily disease becomes apparent on the plants.

The guinea photograph, sent in by MRS. CRESWELL, *Ewhurst, Surrey.*



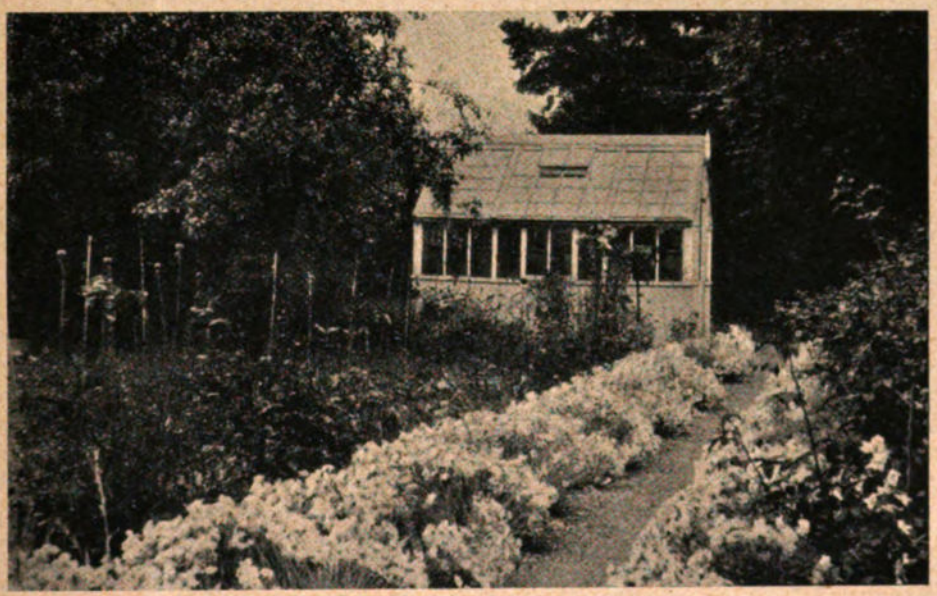
Japanese anemones are excellent for planting in a narrow border by the house wall. They prefer a shady and fairly moist situation and once they are established, the clumps require little or no attention, since they bloom well every year. H. THOMSON, *Newnham-on-Severn, Gloucestershire.* Award of 5s.

Digitized by Google



This photograph shows a winding rock wall covered with aubrietias, white and purple thyme, genista, alyssum, double arabis, dianthus, together with bushes of Cytisus præcox on the right and C. præcox albus in the corner. These plants make a blaze of colour from April until June. The climbing rose in the background is Rosaline Wrench and the crevices between the flags are planted with chionodoxas and crocuses for early flowering.—D. COULMAN, *Goole, Yorkshire.* Award of 5s.

This rockery, laid down and planted three years ago, divides the two small lawns, which are on different levels. A winding path runs between, and on reaching the two pyramid yews the path turns left and right. In the foreground is the top of a 3ft. dry wall, planted with helianthemums, pinks, lavender, London Pride, thrift, etc. On the upper and lower sides of the lawns are herbaceous borders. Each lawn is 36 feet long by 17 feet wide.—C. UNDERHILL, *Canterbury.* Award of 5s.



White pinks, such as the well known Mrs. Sinkins, make a most effective edging. Both in flower and foliage pinks are particularly attractive and, moreover, they are easily grown.—MISS M. WILLIAMS, *Cirencester.* Award of 5s.

CLEMATIS MONTANA DRAPING A HOUSE WALL.

For covering a house wall, there are few quicker growing climbers than Clematis montana. This year the show of blossom has been very fine and the festoons of pure white starry blossoms overhanging the windows have given an added attraction to the house front.—MISS E. FRASER, *Lydney, Gloucestershire.* Award of 5s.

This wistaria is growing on the front of a house just on the outskirts of London. The plant is about fifteen years old and for the last six or seven years has bloomed well every spring and given a second crop of bloom later in the year. This year it is, however, exceptionally fine. In addition to what is shown in the photograph, it spreads over the top of the first floor windows, where, as it is not so massive, the graceful habit of the plant is well seen.—MISS H. MACKHENZIE, *Acton.* Award of 5s.

WISTARIA OVERHANGING A TRELLIS PORCH.

FRUIT AND KITCHEN GARDEN

A Destructive Raspberry Pest.

A COMMON and destructive pest on raspberries is the raspberry moth or raspberry bud caterpillar. All growers of this fruit should keep a look-out for the moths in June. These are from ½in. to ¾in. across when the wings are fully expanded, and they are light brown in colour, having several bright yellow spots on the front wings. In the sunshine the moths have a curious sparkling appearance, and, even though small, are really rather conspicuous. The moths lay batches of eggs and, in due course, tiny caterpillars appear. It is generally believed that these do only a small amount of damage during the first year and, with the coming of the autumn, the larvæ, which are bright red and with brown heads, descend to the soil, where they pass the winter. In the following spring the grubs come up from the earth and climb up the canes. They open their attack on the tips of the young shoots, eating their way down the centre through the pith of the stem. The result is disastrous, and it is rarely that an attacked cane recovers. When the caterpillars are fully fed they turn into ¼in. chrysalids in flat white cocoons which are ¼in. in diameter. These are generally to be found in the cavities at the bases of the buds, though at times they may be placed in other situations. The perfect insects emerge about three weeks after the forming of the chrysalids. In fighting the raspberry moth the following points should be borne in mind. As the caterpillars hibernate just under the soil, deep forking will disturb and carry many to a depth from which they cannot come up. Hoeing with a three-toothed hoe can also be carried out with advantage. Raking away the soil and earthing up again has also been advised. Hoeing in soot or lime, or the two mixed together, will kill the grubs or make the soil thoroughly distasteful to them. In bad cases cut canes back and remove any stakes that have been employed, putting in fresh ones. Attacked canes are much better removed at once, as no fruit can be expected from them. All infected growths should be burned at the earliest possible moment.—L. B.

Intermediate and Maincrop Carrots May Still be Sown.

THE intermediate varieties may still be sown in heavy soils. It is advisable to pay extra attention to such soils and reduce all lumps almost to a powder, not only on the surface, but for at least 9ins. down. After the spring potting of plants there is usually some good old potting compost available, and all such, passed through a fine-meshed sieve, would be splendid for mixing with the original soil. If a fair proportion be used in the open drills and also for covering the seeds, it will be possible to have firm soil immediately around the resultant seedlings, which is very important where the soil is hard and lumpy. The stump-rooted carrots are also well suited for growing in soils of this description, and the present is a very good time for the seed sowing. All carrots should be thinned out at an early stage of growth. Frequently one sees beds of young carrots with yellow and bronze leaves soon after the work of thinning has been done. If bronzed without the yellow tint it is very likely caused by iron in the soil. But the yellow foliage is caused by the grub of the carrot fly. When rather advanced in growth, before they are thinned, the holes made are large enough for the carrot pest to enter, and when once the tender roots are attacked a satisfactory cure is impossible. Thin out the plants while small and, if convenient, while the soil is moist. Whether rain comes or not, water the bed thoroughly immediately the thinning is completed, to wash down fine soil firmly around the roots retained. Afterwards use the Dutch hoe every week to ensure a fine dust mulch, and the plants will make good progress.—CHRISTCHURCH.

Beetroot to Sow Now.

ALTHOUGH the beetroot is much hardier than some people suppose, it is not always a wise plan to sow too early and early sowings ought always to be of the globe or turnip variety. A good strain, like Dobbie's Selected, Egyptian or Bath's Crimson, may safely be sown at the present time in a warm border; see that the soil is not too loose and sow in drills a foot to 15ins. apart. Thin out to 9ins. The tap-rooted varieties may also be sown now; this may be considered rather late to start by some readers, but I speak of average conditions. The soil selected for them must contain no fresh manure and yet it must be fairly rich, either from a heavily manured previous crop or from manuring and digging last autumn or winter. Sow in drills 15ins. apart and thin to 9ins. or 1ft., beat the soil moderately firm again, after sowing. Good varieties include Dobbie's Purple, Prizewinner, Goldie's Exhibition and others. I might add, too, that growers who have a retentive, stiff loam to deal with should grow nothing but the globe variety; if the deep rooting kinds are only moderately successful, try the stump-rooted Dell's Dwarf Crimson or Veitch's Intermediate. Again, there are the non-bleeding beets, like Bell's Deep Red, which have an obvious advantage over others, while other points are up to or over average. Before sowing beet, I always like to rake in 2oz. per square yard of a good mixture of artificials, which I find to be distinctly advantageous. After thinning, a further sprinkling may also be given.—CLYDESDALE.

How to Grow Summer Spinach.

THIS is a quick growing plant if it is rooting in a rich, moist soil. The plant is grown for its succulent leaves, but, unless, as stated, the soil is rich, they are small and borne on hard stems. Also, it is a plant that thrives in a little shade, such as that cast by two rows of peas. Spinach roots almost straight down; few roots spread and because of this the spinach crop, grown between rows of peas, does not rob the latter nor is the plant interfered with by the other crops. Dig the soil deeply, put in some well rotted manure, draw shallow drills, if the soil is dry fill them with water, sow the seeds thinly and cover them with dry soil; do not water afterwards. Thin out the resultant seedlings, while small, to 6ins. apart and, in dry weather, hoe frequently to create a dust-mulch. If extra large leaves are required, thin out the seedlings to 1ft. apart. The round seeded variety is the best for summer use. Sow small batches and frequently to keep up an unbroken supply. The New Zealand spinach is liked very much in some households. Its habit is trailing like that of the vegetable marrow. For each plant make the soil rich over a space 3ft. across and allow a distance of 9ft. from plant to plant. The leaves are very succulent and should be gathered from the base of each stem outwards towards the extreme point. Train the shoots in every direction so that each one will have ample room in which to grow. Confine the plant to the main stems; do not stop them with a view to having a number of side branches as the latter do not bear such large succulent leaves as the main ones.—HANTS.

MORE ABOUT THE CHELSEA SHOW

(*Continued from page* 376).

ORCHIDS.

The best group of orchids shown by an amateur came from Sir Jeremiah Colman, Bt., Gatton Park, Surrey, who had a specially fine series of Lycaste Skinneri, the rare L. locusta, with dark green flowers, a good specimen of Dendrobium acuminatum, the attractive D. Gatton Sunray, and well grown plants of Odontoglossum Wilckeanum Colmanii, with flowers of golden yellow colour.

From the Exors. of the late Mr. H. T. Pitt, Stamford Hill, came a selection of species and hybrids, the former represented best by Anguloa Clowesii, commonly known as the cradle orchid, and by the pretty Epidendrum Endresii. Hybrids were seen in richly coloured odontiodas and blotched odontoglossums.

Messrs. Stuart Low and Co., Jarvisbrook, Sussex, staged the new Odontioda Canberra in their group of various orchids. Another plant of interest was Odontocidium Edwardatum. Of the numerous hybrids, Rolfeare Charm, of apricot colour, and Cymbidium Erica var. Lord Lambourne came in for appreciation.

Messrs. Sanders, St. Albans, had an attractive group in one of the corner places. Among the many fine things were Phalænopsis Rimestadiana, a very good example of Bulbophyllum macrobulbon, as well as the scarce Cymbidium Huttonii, with pendulous spikes. Oncidioda Mauricei had a white lip, backed with deep rose sepals and petals.

Messrs. Charlesworth and Co., Hayward's Heath, had a large selection of hybrids, including Odontoglossum Imperator, of round formation, large and richly coloured. Masses of Lælio-Cattleya G. S. Ball imparted bright orange colour to this group. An interesting hybrid was Vuylstekeara Melba, while a special feature was the fine strain of home-raised Odontoglossum crispum.

Messrs. H. G. Alexander, Limited, Westonbirt, Tetbury, Glos., arranged an extensive exhibit in which Miltonia vexillaria var. Snowflake made a fine show. Other attractions were the Westonbirt variety of Cattleya Tityus, C. Enid var. Gloriosa, and the elegant Dendrobium Dalhousieanum.

Messrs. Black and Flory, Slough, staged the new and interesting Burrageara Windsor, of multigeneric origin. Also a promising batch of Miltonia vexillaria seedlings, as well as numerous cattleyas such as C. Cowaniæ alba, C. Tityus, C. Gildenii and C. Prince Shimadzu.

Messrs. J. and A. McBean, Cooksbridge, had many attractions in their exhibit, of special merit were Odontoglossum illustrissimum, the well known Masdevallia Harryana, the curious Cœlogyne Burfordiensis, with greenish yellow flowers; Cattleya citrina, with pendulous spikes of citron yellow blooms, and an extensive series of Odontiodas.

Messrs. Cowan and Co., Southgate, showed the pretty Dendrobium Devonianum, D. Victoriæ-reginæ, and the elegant Cœlogyne Mooreana in their group. The whole of the centre part was effectively filled with scarlet and red odontiodas.

Messrs. Cypher and Sons, Cheltenham, staged several fine forms of Cattleya Mossiæ in their group, also Lælio-Cattleya Dominiana with a spike of five richly coloured flowers, and the golden yellow Dendrobium chrysotoxum.

Messrs. Mansell and Hatcher, Rawdon, York, showed many very promising seedlings

Digitized by Google

of Miltonia vexillaria, also the scarce Vanda Bensonii, Angulos Cloweaii, Zygopetalum crinitum, as well as a good selection of brightly coloured odontiodas and blotched odontoglossums.

AWARDS TO EXHIBITS.

Among the chief awards were the following :

CHALLENGE CUPS.

Gold Medal and Sherwood Cup for the most meritorious exhibit in the Show.—Mr. G. G. Whitelegg.

Gold Medal and Cain Cup for the best exhibit shown by an amateur.—Sir Jeremiah Colman, Bt.

GOLD MEDALS.

Gardens.—Messrs. Bakers, Limited.

Sweet Peas.—Messrs. R. Bolton and Son ; Messrs. Dobbie and Co., Limited.

Orchids.—Messrs. Charlesworth and Co.

Fruit and Vegetables.—The Hon. Vicary Gibbs ; Messrs. Sutton and Sons.

Mixed Groups.—Messrs. R. Wallace and Co., Limited, for mixed group of lilies and other bulbous plants, irises, herbaceous plants and rhododendrons.

Greenhouse Plants.—Messrs. James Carter and Co. for cinerarias, gloxinias, petunias, schizanthus, calceolarias, clarkias and other flowering plants from seed ; Messrs. Sutton and Sons for salpiglossis.

Carnations.—Messrs. C. Engelmann, Limited, for carnations ; Messrs. Allwood Brothers for carnations and pinks.

NEW AND RARE PLANTS.

FIRST CLASS CERTIFICATES.

Azalea John Jennings.—Apparently this is one of the many beautiful hybrids that were raised at Knap Hill. The flowers are a little larger than those of the Ghent azalea and are of a vivid ruby crimson tone. Shown by Mr. Lionel de Rothschild.

Cornus florida var. rubra.—The illustration in the *Botanical Magazine*, t. 8315, rather glorifies this large deciduous shrub, but, nevertheless, it is very beautiful. The large bracts are lined and stained with bright pink.

Daphne aurantiaca.—To many this was the best new plant in the Show. It makes a sturdy little evergreen bush with ovate dark green leaves, and pairs of bright yellow flowers are borne in the axils of the leaves. The flowers have a slight daphne fragrance.

AWARDS OF MERIT.

Aponogeton distachyon var. aldenhamense.—Except in point of size there does not appear to be much difference between this and the type. Shown by the Hon. Vicary Gibbs, Aldenham House, Elstree.

Aster alpinus Shirley.—A splendid dwarf border plant. Although not much more than 6ins. in height, the plants bear plenty of bright mauve flowers 3ins. in diameter. Shown by Messrs. B. Ladhams, Limited.

Azaleodendron Galloper Light.—A very showy deciduous variety. The rosy salmon flowers are rather larger than those of the Ghent azalea. Shown by Mr. Lionel de Rothschild.

Begonia Mrs. A. Baldwin-Bartock.—A very beautiful double-flowered tuberous-rooted begonia. The flowers are very large, perfectly formed, of rose pink colour.

B. Mrs. F. Bedford.—Another magnificent begonia. The large double flowers are of cream colour flushed at the back and on the edges with light pink. Both begonias were shown by Messrs. Blackmore and Langdon.

Cercis racemosa.—Like the better-known Judas tree, C. Siliquastrum, this small tree bears flowers on the old branches, but they are in little, semi-pendulous racemes and of flesh pink colour. It is a very attractive deciduous tree, becoming about 20ft. high. Shown by Mr. Lionel de Rothschild.

Clerodendron fragrans.—This very fragrant, warm greenhouse plant is by no means new. The pubescent leaves are very large and the flowers are crowded in a small bunch. Shown by Sir William Lawrence, Bt.

Cytisus Lord Lambourne.—A pretty little broom much the type of Cytisus Dallimorei. The flowers have primrose-coloured keels and standards and crimson wings. Shown by Messrs. C. Watson and Sons, Limited.

Dianthus Allwoodii Susan.—The flowers are very shapely and of blush pink colour with a broad deep crimson zone. Shown by Messrs. Allwood Brothers.

Hippeastrum pratense.—This gorgeous scarlet lily was shown as Habranthus pratensis. It was introduced from Chili in 1840, and is nearly, but not quite, hardy. The flowers are borne in an umbel on a spike about a foot high. Shown by Mr. R. C. Notcutt.

Hydrangea Hortensia D. B. Crane.—A handsome truss of substantial deep old rose flowers. Shown by Mr. H. J. Jones.

H. H. Mrs. Baardsi.—A large truss of bright pink flowers.

H. H. Deutschland.—A very large truss of pink flowers lightly shaded with blue mauve. This and the foregoing were shown by Messrs. J. L. Endtz and Co.

Lewisia rediviva Vancouver Variety.—An interesting little plant which, having a very stout, fleshy rootstock, has great powers of recuperation. The entire plant is not more than 3ins. high. It makes a tuft of narrow, fleshy leaves and has solitary pink cactus-like flowers almost 3ins. in diameter. Shown by Mr. C. van Tubergen.

Lupinus polyphyllus Countess of March.—This herbaceous variety has tall spikes which at first are white but soon become flushed with lilac. Shown by Mr. G. R. Downer.

Magnolia Nicholsiana.—A deciduous species from China. It becomes about 20ft. high and has ovate-oblong leaves with fine hairs on the stalks and along the midribs. The white flowers are saucer-shaped, about 4ins. across and have purple stamens. Shown by Lady Aberconway, Bodnant, North Wales.

Pæonia Hiatt C. Baker.—This is a tree peony which has small, round, orange-flushed flowers. Shown by the Almondsbury Gardens.

Pitcairnea aphelandræfolia.—A showy bromeliad introduced from Para in 1867. It has a dense tuft of dark green lanceolate leaves and racemes of bright scarlet flowers. Shown by Sir William Lawrence, Bt.

Carnation E. Lyall Swete.—This splendid border variety has large, well formed bright scarlet-crimson flowers. Shown by Mr. J. Douglas.

C. Evelyn.—This is a medium-sized perpetual-flowering carnation. The white-ground flowers are very heavily stippled with pink at the edge which shows occasionally as lines or flakes. Shown by Messrs. C. Engelmann, Limited.

C. G. K. Phillips.—A very fragrant perpetual-flowering variety. The large, shapely flowers are of rich crimson colour and are delightfully scented. Shown by Messrs. Hewitts, Limited.

Primula microdonta var. alpicola.—This handsome Chinese primrose has a scape about 2ft. in height and bearing a goodly number of long-stemmed lemon-yellow flowers. The flower-stems curve close to the calyx so that the blooms face outwards. Shown by Messrs. Oliver and Hunter.

Rhodohypoxis Baumii.—We cannot discover any authority for the generic name, which does not appear in the "Index Kewensis." It is a curious little plant—apparently a moisture-loving alpine—only a few inches high. There is a tuft of stemless, lanceolate leaves which have fine hairs along the edges. The solitary flowers are much like primroses which have no centres—the corolla segments meet curiously. In this plant they are white.

R. rubella.—This is a rose-coloured variety of the previous plant. Both were shown by Mrs. Garnet-Botfield, Albrighton.

Rose Kerbergen.—A beautiful dwarf polyantha variety. It has shapely trusses of little double rich crimson flowers. Shown by Messrs. William Cutbush and Son.

Tulip White Duchess.—A large cottage tulip which has the segments curiously notched. The solid white is relieved by green lines along the centre of the outsides of the segments. Shown by Messrs. Barr and Sons.

Viburnum macrocephalum.—This is a fair-sized deciduous species from China. The dark green ovate leaves are small in comparison with the large rounded trusses of pure white hydrangea-like flowers. Shown by Mr. Lionel de Rothschild.

Viola cornuta Jersey Gem.—A splendid little viola of dwarf, spreading habit and bearing plenty of large royal blue flowers. Shown by Messrs. Watkins and Simpson.

Weinmannia trichosperma.—Unfortunately, this uncommon evergreen shrub from Valdivia is not quite hardy. It bears flattened, pinnate leaves of fern-like appearance, and the pendulous little racemes of small flowers have pretty rose-tipped anthers. Shown by Mr. G. W. E. Loder, Ardingley.

Orchids.

FIRST-CLASS CERTIFICATES.

Lycaste Skinneri var. Mrs. Hamilton Smith, from Sir Jeremiah Colman, Bt. By far the finest form of this well known species.

Odontioda Corregio, from Mr. J. J. Bolton, Claygate, Surrey. A beautiful hybrid, rose-tinted with soft crimson blotching.

Miltonia Lucia var. Stamperland, from Mr. Robert Paterson. The flowers are distinct by reason of the well developed blotch on the lip.

Cattleya Prince Shimadzu superba, from Mrs. Robert Paterson. A charming variety of soft rose colour, the labellum richly coloured with purple and gold.

SUNDRIES.

GREENHOUSE AND HEATING APPARATUS.

In the main avenue at Chelsea, greenhouses, both large and small, and heating apparatus of every type were on show. Messrs. Skinner, Board and Co. had erected one of the "Wiretension" greenhouses which has a curved roof with flat glass, and in which woodwork and putty have been cut down to a minimum. A very useful small alpine plant house was shown by Messrs. Boulton and Paul ; and a well constructed small propagating house by Messrs. D. Swain. Messrs. Duncan Tucker erected a house which would serve equally well for a cool conservatory or a heated house for general purposes. Engines, pumps, boilers and heating apparatus

were displayed by Messrs. C. P. Kinnell, who are specialists in this line. A number of other firms had exhibits of this kind, including Messrs. Hayward and Co., who had a very useful set of portable hand lights in varying sizes; and Messrs. Messenger and Co. who showed frames, greenhouses and boilers.

Tools and Spraying Machines.

Considerable interest is always aroused by the exhibits of gardening tools and spraying machines. All the most up to date patterns and the latest inventions were on show and numerous firms displayed comprehensive collections of tools, sundries and gardening requisites of every description. Messrs. T. Gunn had an excellent exhibit of useful garden implements. Forks, spades, cutting tools of all kinds, were exhibited by Messrs. R. Melhuish, Messrs. W. Wood and Messrs. J. Carter. The well known "Rain-King" lawn sprinklers in various sizes, suitable for hard tennis courts, as well as small grass lawns, were shown by the Cooper-Stewart Engineering Co. On the stand of Messrs. Joh. Hansen, practical demonstrations of the "Little Wonder" hedge clipping machine were given. This is a most efficient and labour-saving implement. The Four Oaks Spraying Machine Co., had a representative collection of the syringes and spraying machines which have been used throughout the horticultural world for many years. Bucket sprayers, pneumatic sprayers in various sizes, (all fitted with this firm's special unchokable nozzle) powder sprayers and lime-washing machines were on show. Some very serviceable and well made secateurs and pruning knives were exhibited by both the Wilkinson Sword Co. and Mr. C. Jardine. Some of the pneumatic spraying machines displayed by Messrs. Holder Harriden and the Eclipse Spraying Co., are particularly suitable for use in a greenhouse or small garden. Gardening tools for children were shown by Miss M. Nader, and Mr. B. J. Walker was demonstrating the new "Rolcut" secateurs, which have a different cutting motion from the ordinary type of secateur. The "Rolcut" makes a clean roller cut and does not bruise in any way. These secateurs not only make a clean cut without a bruised, jagged edge, but they are light to use and made of good quality material. Tools, hoses, a selection of tools, fertilisers, weed killers, etc., were shown by several firms, including Messrs. Smith and Ellis, Messrs. E. J. Woodman and Messrs. A. Smellie. The "Everon" tap union was one of the useful hose fittings shown by Messrs. A. Smellie. The Shoulder Hoe Co., were exhibiting their new patent hoe, and lawn accessories of every kind were shown by Messrs. H. Pattisson.

Garden Furniture.

A large number of exhibitors were displaying garden furniture. Seats, tables, chairs and benches made of teak were shown by several firms, those made by Messrs. Castle from old man-o'-war teak are particularly good in design and workmanship. Messrs. Abbott Brothers showed a collection of garden furniture together with birds' nesting-boxes and table trays. A summer-house of good design was exhibited by the Papworth Industries, and Messrs. A. Overend had rustic furniture and a rustic summer-house. Some very well made osier furniture and sets of tables and chairs made by disabled soldiers at the Lord Roberts' Memorial Workshops were to be seen, and the London Association for the Blind also had a number of somewhat similar articles. "Citadel" chairs shown by Messrs. W. Sinton were most comfortable. They are made of sea grass, which is pliable and yet does not creak. Strongly made oak plant tubs with hoops and fittings of antique brass were also seen on the stand of this firm. Cane chairs of the very best quality were displayed by the Dryad Works, and such well known firms as Messrs. A. W. Gamage and Messrs. Harrods had good selections of portable garden furniture, swing hammocks, as well as tents and shelters. Messrs. W. Wood and Messrs. Gaze also displayed a good selection of teak garden seats and chairs, and a garden shelter made of natural osier by the Rural Industries is well adapted for the week-end or seaside cottage garden. Other firms, too numerous to mention, had interesting exhibits of garden furniture.

Garden Ornaments.

Ornaments of lead, natural stone, terra cotta and various forms of artificial stone were exhibited. The Bromsgrove Guild had a number of ornaments of good design, and particularly attractive were some of the small lead figures which they were showing. A great variety of bird-baths, fountains, vases, stone seats in artificial stone were displayed by Messrs. Sanders and Co. Some of the stone baskets of fruit shown by Messrs. Pulham were much admired; and the large vases in grey and red terra cotta shown by Messrs. Wakeley Brothers were most inexpensive and yet effective. Other firms, such as Messrs. Hodsons, Messrs. A. Moorton, Messrs. Burton Holt, and Messrs. W. Wood, all exhibited a good selection of artistic ornaments for the garden.

Insecticides and Fertilisers.

It would be impossible to give a full account of the many different insecticides and fertilisers which were seen on all sides at the recent Chelsea Show. It is evident that there has been great progress in the science of these matters, for one can now obtain specialised plant foods, insecticides and fungicides to combat every common pest and disease in our gardens, as well as weed-killers, soil fumigants and stimulants for lawns on various soils. Messrs. Cooper, McDougall and Robertson had their famous Katakilla, which is such a valuable aid in the garden during the summer months. Tree-banding materials, "Weedicide," lawn sand and fungicides were also shown by them. Messrs. Robinson's Multiple Slug-killer and Anti-clover Fertiliser for lawns were other very useful materials on show. Fumigating compounds, including XL-All, and nicotine compounds were seen on the stand of Messrs. G. H. Richards. Quassia extract, lawn sand, "Weed-death," lime sulphur wash, and special material for destroying ants and woodlice, and the "Little Marvel" wasp traps were some of the interesting features shown by Messrs. Corry. "Tarbol," which has been proved to be most effective material for ridding the ground of soil pests, was exhibited by the fertiliser specialists, Messrs. J. Fison. "Tomorite" (a properly balanced food for tomatoes), fertilisers for chrysanthemums, roses and greenhouse plants, as well as pure ichthemic guano, were shown by Messrs. Prentice Brothers. The Acme Chemical Company, whose weed-killers, both poisonous and non-poisonous, are extensively used, showed "Fumerite" (a compound for destroying ground vermin), lawn sands, manures, and insecticides for all purposes. Messrs. Adco had an exhibit of synthetic farmyard manure made from garden rubbish by the "Adco" process.

A complete garden fertiliser which acts as a stimulant for fruit, flowers and vegetables, was displayed by Messrs. Price and Co. The Garden Supplies, Limited, were demonstrating the value of their "Climax" lawn sand; and on the stand of Messrs. Wakeley Brothers, among fertilisers, potting soils, ground garden lime and hop manure, was a material known as "Humull," which is composed of decayed vegetation rich in humus, and is an excellent top-dressing for lawns.

SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry.*

We have selected the following enquiries with their answers, as being of more general interest, and therefore worthy of publication.

Lupins which do not Flower Well.

I should be very glad if you would advise me what to do for lupins which drop their blossoms before they are fully developed, so that only an inch or two of blossom or none at all is left on the spikes. Other lupins in the same bed do well.—O. C., Kensington, W.8.

Evidently the lupin plants on which the flower spikes fail are unhealthy at the roots. The condition of the flowers points to a grub attack, possibly wireworms. Take up a root and examine it. If grubs are found or fungus, treat the soil next autumn with "Vaporite," and one month later, with formalin solution at full strength.

Pruning Ceanothus Veitchii.

I have a fine bush (or small tree) of Ceanothus Veitchii, trained on a south wall. The bush is coming out into a perfect mass of flower and will be a fine show. I think I have read that it should be pruned as soon as the flowers are over, but have no idea as to how much. Should I cut back all outstanding shoots and if so, to what extent?—C. R., Reading.

As a bush in the open Ceanothus Veitchii requires no system of pruning, thus on a wall you need only shorten the growths to accommodate the plant to its position. This object would perhaps be best attained by shortening the growths to within 6ins. to 9ins. of the wall as soon as the blooms fade.

LYPTICIDE

THE FIRST INSECTICIDE TO USE

NATURE'S INSECT KILLER

EUCALYPTUS OIL.

No insect, no fungus ever attacks Eucalyptus leaves. But the oil is too strong for spraying, cost prohibitive, and oil and water won't mix. By a newly patented method, LYPTOL LTD. produce

LYPTICIDE

a transparent amber liquid in which the oil is permanently suspended and can be mixed with water to any extent, costing (green fly strength)

only 2d. per gallon.

It kills every insect and fungus it touches with a certainty unknown before, yet is non-poisonous and harmless to the tenderest leaf.

NO SLUG, APHIS NOR CATERPILLAR WILL EVER ATTACK A LEAF SPRAYED WITH LYPTICIDE.

T. G. W. Henslow, Esq., M.A., M.B., F.R.H.S., the well known authority on horticulture, tested Lypticide unknown to us and wrote a long enthusiastic letter:

". . . you have a great future in your discovery; no garden can afford to be without it."

Use it and see for yourself.

Price: 2/6 per pint; 9/- per ½-gallon; 15/- per gallon.

Obtainable from LYPTOL, HARROW.

Agents for Berks and Bucks:—
WM. WOOD & SON, LTD., TAPLOW, Horticultural Specialists to H.M. The King.

Agents for Midlands:—

A CLUMP OF ÆTHIONEMAS ON A ROCKERY.

ALTHOUGH Æthionemas are showy and beautiful plants they are seldom met with in the ordinary garden. They are sun-loving plants, and if given a position on a dry wall or rockery bank facing south they will establish themselves readily and provide a brilliant display of colour year after year during the early summer months. There are a number of species and varieties varying from about 6—12 inches in height and forming trailing mats studded with vivid rose or white blossoms. They will thrive in any poor, gritty, well-drained soil.

THE USE OF GARDEN WASTE

NOWADAYS it is generally recognised that the best results in the cultivation of flowers and vegetables can only be obtained by the use of plenty of manure, both natural and artificial.

In the summer a pile of lawn mowings will constantly be accumulating and these should be spread over the soil among the plants to check the weeds and to keep the ground moist. Not a scrap of green stuff should be wasted, but should be thrown on the heap to be used as manure.

The borders should be trenched in the autumn. That is, the trench should be two spits deep and a thick layer of the manure and decayed vegetable rubbish forked into the bottom spit. This keeps the soil rich and damp throughout the summer months, when the plants send their roots deep into the ground to find moisture. Provided that all the green stuff is saved throughout the summer and autumn, and not burnt, enough vegetable manure will be obtained to enrich the soil during the following year.

A large part of the garden refuse cannot be used in this way. Stalks, prunings and weeds must be burnt; a few big bonfires yield a surprising amount of ash, and thus, supplemented by a little bone meal and soot, is used as the fertiliser. Ashes being rich in potash are extremely valuable to the gardener and should be scattered evenly on the top spit and lightly raked in. Soot, which should first be exposed to the air for some weeks in a tub or box, makes an excellent liquid manure: a bag full of soot is suspended in a can of water, and this liquid sprinkled on the ground.

Every autumn there will be considerable quantities of fallen leaves. These should be carefully swept up and stacked in a heap, together with lawn mowings and other soft garden refuse. This heap should be occasionally turned over, and a little "Adco" mixed with it to hasten the process of decomposition.

In this way the garden will be, so far as manure is concerned, practically self-supporting; every two or three years a load of cow manure is helpful, but this is not essential. The whole idea is to put back into the ground as much as you take out of it.

Æthionemas for the Rockery.

THOUGH, perhaps, the most beautiful of all the crucifers, the æthionemas are not as a rule, well represented in the average rock garden. This may be due to the fact that they are southerners and insatiable sun-lovers and therefore rather untrustworthy in wet winters. But give them a sloping bed of really poor, gritty or stony soil, place them between the chinks of a rock, or with their roots under a stone at the top of a dry wall, always with full exposure to the south, and most of the better known kinds will prove as permanent as one could desire. Limestone they all love, but it is not so essential as that prime necessity—free drainage and a rocky root-run.

Æ. Warley Rose is not only the best of its race, but one of the best and brightest rock plants in cultivation, covering its steely-blue foliage with abundant flowers in a vivid rose-carmine throughout April and May. It makes a neat little bush about a foot across and half as high. If Æ. Warley Hybrid may be described as the same thing in rather a paler colour, it is so good and so brilliant that it is not until you grow the two within eye-shot of one another, that one appreciates the real difference between them. Both of these are not only first-class æthionemas, but they are among the easiest and most reliable. Æ. grandiflorum of the lists is another little bushling of about 1ft., with abundant heads of flowers in a vivid rose and Æ. pulchellum covers its glaucous foliage with blooms of a soft chalky pink. Another excellent species is Æ. iberideum, which is as easy as arabis and one that makes lovely mats of silvery foliage which is almost hidden beneath a wealth of white, hay-scented flowers from March to May. All the æthionemas are very easily propagated by cuttings of short, half-ripened shoots struck in pots of sandy soil in a cold frame in the later summer. The only attention the growing plants may require is an occasional cutting hard back of straggling growths in early spring. Then as soon as the blooms are over (end of May) all the flowering shoots may be well shortened, this conducing to a more compact growth and, as often as not to a second crop of bloom in the late summer.

Walthamstow and District Gardens Guild.

IN conjunction with the London Gardens Guild, a competition is to be held by the Walthamstow and District Gardens Guild. There is a strong desire to form a society in this district to arrange shows and garden competitions and any readers who reside in this neighbourhood and who are interested should communicate with Mr. A. Charles Sarson, 33, Elphinstone Road, Walthamstow.

Aldenham House Gardens.

THE gardens of Aldenham House, Elstree, will be again open to the public, by kind permission of the Hon. Vicary Gibbs, on the Saturdays of July, August and September (other than Saturday, July 16th, the date of the Elstree Floral Fete, when admission will be gained on payment at the gates); also on August Bank Holiday (Monday, August 1st).

This Week's Work

For Gardens in the South and Midlands.

Trim all hedges and evergreens.

Remove the faded blooms on flowering shrubs, and place azaleas outside in a sheltered position.

Plant out cabbages, celery and winter greens, and earth up potatoes.

Stake and tie all tall-growing annuals, perennials and border carnations.

Transfer winter-flowering pelargoniums to a cold frame.

Keep down pests on fruit trees and roses.

Sow late peas and feed chrysanthemums and tomatoes in pots with weak liquid manure.

Thin out the berries in the bunches of grapes.

This Week's Work

For Gardens in Scotland and the North.

Mulch raspberry beds with decayed manure.

Pinch out the points of broad beans when 3ft. high.

Remove seed heads from rhododendrons and other shrubs.

Take out top bud of clarkias, godetias, and marigolds to promote bloom on side shoots.

Dust onion, carrot and turnip beds with soot and lime.

Sow cineraria seed in pots or boxes.

Remove root suckers from roses and fruit trees.

Transplant begonias in beds.

Shift primula seedlings when the pots are full of roots.

Make a small sowing of aquilegia out of doors.

Digitized by Google

PLANTS FOR DRY AND SHADY PLACES

There is always a difficulty in finding plants which will succeed in a dry and shady situation in the garden. In the following article is given a selection of suitable subjects which the amateur can plant with success.

A DRY border that gets little or no sun presents one of the most difficult problems that a gardener is called upon to face, and it is not surprising that the temptation to follow the line of least resistance is often too great to be withstood and the unattractive bit of ground is allowed to become a dull and dismal tangle of stunted "evergreens"—which generally include Portugal laurels and aucubas—and dusty ivy. But given a little enterprise and more patience something may be done even with such a border, although it is vain to expect that it can ever be as gay and floriferous as one that gets a large share of sunshine and moisture.

The first thing to be done when such a border is taken in hand is to consider whether anything can be done to modify the dryness. If there are tall trees at the back, a deep trench should be taken out and any roots projecting into the border cut through. In the case of a wide border, a sunk wall of concrete, bricks or stone can be built in the trench to prevent any further encroachment by the roots, or, as was recommended by a correspondent of THE GARDEN last year, strips of galvanised iron may be substituted for the wall with a great reduction of cost, but it must be well "weathered" before use, as freshly galvanised iron is apt to have an injurious effect on plant life. Should there be a privet hedge instead of trees at the back of the border, its roots may be similarly dealt with, but it will be wiser to replace it by something less of a vampire, such as a hedge of Lonicera nitida or myrobalan plum, although not much bloom can be expected from either under such conditions.

A dry border should be as deeply dug as possible, the subsoil well broken up and farmyard manure, half-decayed vegetable refuse and, if possible, some chopped-up loamy turf worked in if the soil is light. If on the heavy side, strawy stable manure may be substituted for the farmyard stuff and this supplemented by leaf-mould and road sweepings, always provided that the latter can be obtained from untarred roads.

There are very few climbing plants that will flower in a dry and shady border, but quite a good effect can be obtained by growing the large-leaved ivy (regneriana), Rubus biflorus (the whitewashed bramble), the variegated Japanese honeysuckle, the jasmines, nudiflorus and officinale—both these will flower moderately well in shade—and the common hop and its variety aureus on poles. The Japanese hop, usually treated as an annual in this country although really a perennial, is also useful in such a situation. There is a bronze-leaved form of it which is rather effective and certainly unhackneyed, as it is seldom grown. Among plants suitable for the back row of the border—they may be placed between and in front of the poles with climbers—the best are foxglove white and spotted, the blue and white Aconitums Napellus bicolor and N. Sparks' variety, Thalictrum aquilegifolium, Helianthus rigidus (the prairie sunflower) Inula Helenium (elecampane) with its showy yellow blossoms, and the Verbascums phœnicium and nigrum, all of which may be relied upon to flower, if not very profusely.

THALICTRUM AQUILEGIFOLIUM IS A FINE PLANT FOR THE BACK ROW OF A SHADY BORDER.

MANY OF THE YELLOW FLOWERED COMPOSITES SUCH AS INULA CAN BE USED TO ADVANTAGE IN A DRY BORDER.

For the main part of the border we can have honesty (Lunaria biennis), purple and white, the large yellow toadflax (Linaria dalmatica), Œnothera Lamarckiana (the biennial evening primrose), Achillea Ptarmica, and valerian in its crimson, pink and white varieties. The periwinkles, too, are invaluable for such a situation, and should be grown freely. Besides the familiar Vinca major and V. minor, blue and white, there are a pretty double blue form of the latter, a variety of V. major with gold-mottled leaves sometimes known as elegantissima, and the dainty pink-flowered V. rosea, the last named, however, being of rather doubtful hardiness in cold districts. The Rose of Sharon (Hypericum calycinum) will produce its handsome golden yellow blooms with an amiable indifference to shade or drought, and three of the euphorbias, Wulfeni, pilosa and polychroma, and two of the campanulas, latiloba and alliariæfolia, may be tried with a fair prospect of success.

There are several shrubs that are exceedingly useful in a dry, sunless border, these including Berberis (Mahonia) Aquifolium with its shining purple-brown leaves, butcher's broom (Ruscus aculeatus), not very interesting but compact of habit and exceptionally good-tempered, the yellow-foliaged Cassinia fulvida (golden heath) and Euonymus japonicus in its variegated forms, E. aureus and E. albo-marginatus, the two last being specially desirable by reason of their showy leafage. It may be added that the writer has found that Daphne Mezereum, crimson and white, will flower fairly well in such a border, although it is not generally regarded as an appropriate shrub for a situation that is shady as well as dry.

Perhaps the most suitable of all edgings for the border is one of the small-leaved ivies pegged down and kept clipped, but it is rather dull and the variegated form of Euonymus radicans Silver Gem is much more cheerful and nearly as neat. Sweet woodruff, London pride (Saxifraga umbrosa), creeping jenny (Lysimachia Nummularia) and Corydalis lutea will all flower more or less without sun, while another plant that makes a pretty edging is the Welsh poppy (Meconopsis cambrica). This is usually thought to need sunshine, but in the writer's garden there is a colony of the orange variety

Digitized by Google

established in a gravel path under a high hedge which effectually shuts out the sun save for an hour or two during the early morning at midsummer, and the plants flower and even ripen seed abundantly.

A near relation of the meconopsis and also bearing orange-coloured flowers is Papaver pilosum, which will succeed tolerably well without sun, as will also Corydalis lutea, a most amiable little plant that is happy anywhere. The ordinary run of Michaelmas daisies are not satisfactory in a dry and shady place, but the old Aster diffusus horizontalis (Farewell Summer) and A. Linosyris, (Goldilocks) are exceptions. Polygonatum multiflorum (the best variety of Solomon's Seal) will produce its white bells quite profusely even if it is rather stunted in stature; and the same may be said of Anemone japonica, which will bloom, but without reaching its normal height.

FOXGLOVES IN VARIETY SUCCEED IN A DRY AND SHADY POSITION.

Very few annuals will thrive under such conditions. The white-flowered, grey-foliaged Omphalodes linifolia; Calendula officinale (pot marigold), single and double; the blue woodruff (Asperula azurea setosa); and the pretty yellow and white Limnanthes Douglasii, will give the best results. The canary creeper, Tropæolum canariense, will flower freely in shade if it can be supplied with enough moisture. This is best managed by putting a layer of little bits of crock or small stones at the bottom of a 6in. flower-pot, sinking it close to the roots of the creeper and filling it up with water twice a day, or oftener in hot weather.

At the onset of hot weather a dry border should be forked over, thoroughly watered, lightly mulched with strawy stable manure or lawn mowings and the watering repeated. Thus treated it will remain moist for a considerable time.

R. E. H.

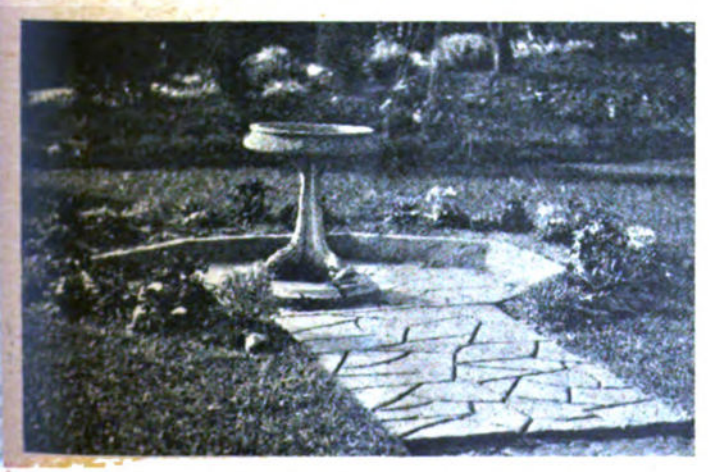
HOW TO MAKE A LAWN ATTRACTIVE

Making a Crazy Path and Planting up a Birds' Bath Surround

I WAS very interested in 'Hamish's" notes on page XXII of THE GARDEN, dated March 26th, 1927, because I made a similar pathway to that described, about eighteen months ago. My pathway was cut through a lawn, the clean-cut edges of which obviated the use of boards for the keeping of the cement mixture in place. Unlike "Hamish," I mixed no colouring matter with my cement, for I required a grey path, which, in time, would become weathered by percolations of water, until it assumed the appearance of old stone. A cement mixture of four bucketfuls of sand to one of cement would give an almost white path when thoroughly dry, and the surface would be proof against all weathers, *i.e.*, the colour would remain white, unless brushed over with a stiff brush when the mixture was nearly dry to remove the scum. Particularly is this so when the constructor makes his paths in the manner advocated by "Hamish," with an abundance of drainage material. In a gravel or other path, this drainage is most necessary, but in a cement path where one wishes a weathered effect to take the place of the rather monotonous grey colour of the cement, the drainage defeats the very object which it is desired to attain. If the water is allowed to drain away beneath the cement, it never becomes stagnant, and cannot ooze through the cement coating to form the green slime which later gives the path such a charming effect. All that is necessary in the preparation of the path is to ram the soil thoroughly when in a moderately dry condition, laying the cement direct on this. If the slabs are shaped up with a trowel, allowing some 2ins. between the slabs, small plants can be inserted in the soil between these blocks.

A much better finish is given to the path if, instead of filling in the interstices with a different coloured cement, soil is brushed into the spaces between the moulded "stones."

A very charming surround for the birds' bath or sundial placed on a lawn, can be constructed in the same manner as the cement path. The sunk portion is first of all cut out of the grass, taking this out to include only the sunk portion, and not the border surround seen in the photograph, which is cut later on when the cement is iron-hard. This gives a clean cut edge for cementing purposes and avoids the use of boards, which are not always present when required. A number of holes some 3ins. deep should be made in these little earth walls while the soil is moist, which can be effected by means of a dibber, or cutting out with a fern trowel. These holes are for the purpose of providing a "key" to hold the cement in position. The cement is made in the proportion of one bucketful of cement to four of sand and mixed with water until it is like stiff mortar. The mixture is then applied to the earth walls and smoothed out with a wooden float until an even surface of cement, some 2ins. thick, has adhered. The flooring of cement can then be laid, either in one flat sheet, marking out into a crazy pattern by means of boards when half-set (as advised by "Hamish"), or the separate "stones" may be moulded, or shaped, by means of the trowel as the mixture is laid. I would recommend the second method, as by this means a much more irregular and broken-stone appearance can be obtained; pieces of wood make rather straight lines, which betray the fact that the path is merely camouflaged, and not the real thing. The path seen in the illustrations was produced by the board method, but others which I have since made by the second method are much more pleasing. P.



SHOWING THE METHOD OF LAYING THE CRAZY PAVING.
Polyantha primroses have been planted round the birds bath.

THE SUNK GARDEN COMPLETED.
The flowers in this border surround are mauve violettas and pink antirrhinums.

CREATING NEW IRISES

When irises are in full flower many amateurs might like to try the fascinating experiment of raising new varieties, in the hope that a new sort of outstanding merit will be obtained. Full details are given in this article as to how to proceed.

UNDOUBTEDLY one of the most fascinating branches of the art of gardening is that devoted to the raising of new plants; something different and better than we already have. This branch is often considered by amateurs to be difficult—work essentially reserved for the specialist. Such, however, is not the case. Any amateur having time and patience can enter the field and his chance of success is equal to that of the professional raiser. In order to produce a new variety, it is only necessary to perform the simple task of taking pollen from one variety and dusting this on to the stigma of another. There are, however, certain factors of which due notice must be taken, as, for example, plants which may be fertilised by insects will have to be protected from insect visits by fixing up a little tent of muslin to enclose the flower, and in dealing with flowers which fertilise themselves it will be necessary to remove the pollen sacks (anthers) to prevent this. Not infrequently, the anthers discharge the pollen before the flowers open, as in sweet peas and campanulas, and in this case the somewhat delicate operation of removing the anthers from young buds must be undertaken. As regards the stigmas, these must be in a proper condition to receive the pollen, and this usually means when they are somewhat viscid. All these and other minor points which need not be mentioned are really matters of commonsense and are easily dealt with after a little practice. The amateur should not choose a plant which produces an abundance of seed, as the poppy or verbascum, because it will be quite impossible to deal with thousands of seedlings in the average garden. The real difficulty of this work lies in the fact that only a very small percentage of the resulting seedlings will be found to be any advance on existing plants—it is largely "a game of chance," but as colour, habit and other qualities in a plant are matters of personal taste, it is probable that the amateur may raise many plants which please him. The work is as fascinating as a good serial story. First transferring the pollen—then a period of uncertainty, with daily visits to the flower to see if the capsule is swelling—the watching of the capsule and gathering of the seed—the sowing of the seed—a further anxious period, waiting to see if the seed will germinate—the care and transplanting of the young plants—then the pause for the final chapter—the buds are showing, the flowers will soon appear! At this moment one must suppress the springs of hope, as it is not unlikely that disappointment may be complete. There is a strong element of chance in this work, making it possible for an amateur to produce in his first attempt a plant of outstanding merit, perhaps one for which professional raisers have long striven.

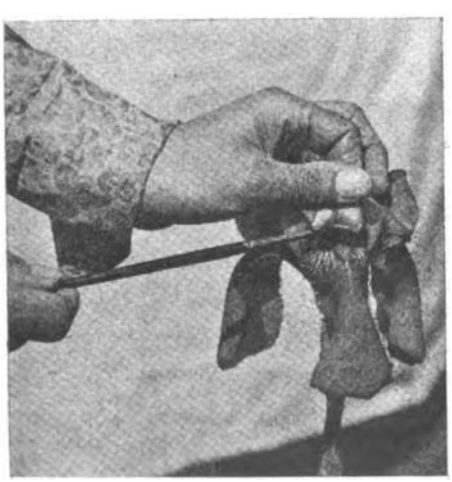
A SPIKE SHOWING MATURE SEED CAPSULES.

I would particularly recommend irises as a most accommodating race of plants, suitable in every way for those who decide to attempt to raise something new. They are rarely fertilised by insects or self-fertilised, so that no nets are required, and, although it is advisable, it is not imperative to remove the anthers. Irises do not produce a large amount of seed, and there is generally sufficient room in the average garden to accommodate the seedlings. I will therefore describe the operations necessary to raise new irises. Indiscriminate crossing is not likely to yield good results, and one should have a definite aim, so that parents which appear most likely to satisfy that aim may be chosen. For example, one might wish to produce very early or late flowering varieties, very tall or strong varieties, or a particular colour, or to engage on work which has not received much attention by other raisers, such as the production of sweetly scented varieties. An instance of a particular aim would be the production of a really good, tall, late-flowering white iris. To do this, one might select the well known Pallida dalmatica as the parent necessary to provide the factors of height and lateness, and the factor of being white must be introduced from any suitable white iris which happens to be in bloom at the time. Having decided upon the aim for which you must strive, pluck and examine an iris flower and compare it with the diagram which gives the names of its parts. Take hold of the crests with the finger and thumb and pull them back gently, when the viscid surface of the stigma will be exposed, and this is where the pollen must be placed. Just underneath this limb the anther will be seen. When collecting pollen, remove the anthers with a pair of forceps. The pollen may be transferred to the stigma of the selected seed parent by means of a soft brush, as illustrated, or simply by holding an anther in the forceps and passing it gently across the stigma.

This operation is known as hand-fertilisation, "making a cross," etc., and each flower so treated should be marked with a label bearing a number. Enter the number in a book, and against this put the name of the seed parent and pollen parent, *e.g.*, No. 45, Pallida dalmatica × White Knight, the name entered first being the seed parent. If the cross has been successful, the flower will soon fade and the ovary begin to swell. Should there be several good seed pods on a tall spike, it is as well to support this with a stick, or it may be beaten down by wind and rain.

The seed pods begin to ripen just about the time when most of us are taking a seaside holiday, and so it is best to enclose the pods in small muslin bags before going away, when, should the capsule open, the precious seed will not fall to the ground. When the capsules show signs of opening, cut the spike and store in a dry shed. Should the weather be wet when the capsules are gathered, they may be dried off in a warm place, such as the domestic airing cupboard or on top of the kitchen mantelpiece. In wet autumns I have frequently matured the seed on the top shelf of an airing cupboard.

The ripe seed may be sown outdoors in early October, but it is more satisfactory to sow it in pans, when conditions can be controlled. Fill about one quarter of the pan with crocks to ensure a good drainage, then put a little leaf-mould or fibre over the crocks to prevent the soil from washing through, and fill up with a mixture consisting of about one quarter sharp sand and three-quarters good fibrous loam to which a small portion



TRANSFERRING POLLEN WITH A BRUSH.
The position of the stigma is indicated.

A PAN OF IRIS SEEDLINGS READY FOR TRANSPLANTING.

Digitized by Google

of old mortar rubble or lime has been added. The seeds should be sown quite ½in. deep, as they have a tendency to work towards the surface during winter rain and frost. A good sound label bearing the number of the cross should now be put in, and it will be found useful to mark on this the number of seeds sown. Plunge the pans in the open ground in a position where they are well exposed to frost and cover with a piece of wire netting to prevent birds from dusting in the fine soil and disturbing the seed. About mid-February, preferably after a sharp frost, remove the pans to a cold greenhouse or frame and destroy any slugs, which often winter underneath. The pans should be carefully weeded, and if the soil has shrunk away from the edges, fill the cracks with fine soil. From this time they must never be allowed to get dry; the amount of drainage will prevent a water-logged condition. If once the seed gets dry, it will refuse to germinate that year. When the seedlings begin to show, keep a sharp look-out for small slugs, as they are very destructive. As soon as the plants are about 3ins. high, they may be transplanted into the open ground, provided that the soil is moist and the weather not too hot. A reference to the label may show that only about half the seeds which were sown in the pan have germinated, and a further proportion will germinate next year.

This is the normal behaviour of iris seed, and several cases have been recorded where seed germinated after five to seven years. It will, therefore, be necessary to remove the young plants, so as to leave the soil containing the dormant seed in the pan. To do this, take a wooden label and thrust down the side of the pan near a seedling, then, holding the seedling, gently ease it out. Plant out your seedlings at once, then tidy up the soil in the pan and plunge again in the open, keep free from weeds. Under favourable conditions, about half of the seedlings planted in the open in April will flower the following year. If the hand-fertilisation of selected flowers is continued, the raiser will have a number of new plants coming into bloom yearly, and once he has experienced the thrill of watching the opening buds he will need no further incentive to continue. Even gardening can provide excitement. G. N. BUNYARD.

This outline drawing indicates the various parts of the iris flower.

HERBACEOUS SPIRÆAS AND ASTILBES

These perennials are invaluable decorative plants for placing in any moist corner of the garden. When established they require little or no attention for a number of years.

FOR any cool rich soil or the margin of the water the herbaceous spiræas are invaluable plants. This is not only because they are very hardy, robust and easy doers and extremely showy, but because so many of the handsomest kinds come into bloom towards the later summer, when the garden in general is beginning to lose colour. As a rule, these meadowsweets are sun-lovers, but most of them will do very well in partial shade. Their chief requirements are good living and abundant moisture. Once established they will take care of themselves for many years, only asking for removal of dead stems every winter and a good top-dressing of well rotted animal or vegetable manure.

From no selection of herbaceous spiræas should be omitted the lovely S. palmata, whose broad palmate leaves and wide, flat flower-heads in a vivid rosy carmine and rising to some 2ft., afford a combination of foliage beauty and colour which has no rivals in spiræas of its own stature. S. palmata also gives us a very lovely variety with snow white blossoms, and then there is that delightful diminutive, S. digitata, which, whether it be a form of palmata or not, might be described as a very dwarf replica of that fine spiræa, with all the latter's brilliance of colour. Somewhat of the same type as S. palmata, but attaining more than double its height, is S. venusta (lobata), the Queen of the Prairie, whose magnificent inflorescences are of such a striking hue of raspberry red that they will even eclipse in splendour those of palmata itself. Still taller, towering to 7–10ft., and terminating in bold crowns of rosy white is the splendid S. gigantea.

In the woodland or wild garden, especially when associated with ferns, the flossy milk white plumes of the old S. Aruncus are always attractive, and a more easily grown plant I do not know than this. It also makes a telling background for the dazzling spires of that most gorgeous species, Astilbe Davidii, whose virulent hues are safer with white and green than any other combination. Yet another first-rate white spiræa is our own dropwort, S. Filipendula, of which the double-flowered form is an admirable plant and one, by the way, which will do in much drier soils than most of the genus appreciate.

One astilbe has been referred to, and it is difficult to write of spiræas without trespassing into the realms of the sister genus, so closely are the two races united. But I will not do more here than draw the reader's attention to that race of magnificent hybrids which has been created by the crossing of such spiræas as the old S. japonica, S. sinensis, Astilbe Davidii, A. Thunbergii and others. A selection of these hybrids planted in good soil will make a display of colour throughout July and August which is unrivalled at that and perhaps any other season. These colours range from purest white to cream and salmon rose, from pink to the richest carmine, and when I say that the elegant plumes, are often over 2ft. in length and half as wide across at their base, one can perhaps imagine the effect produced by a few well grown plants.

All of these spiræas grow so freely and are so easily propagated by division or the removal of rooted offsets that a single plant will soon yield any quantity of material for increase. This can be done at any time after the foliage has died down in autumn.

A. T. JOHNSON.

A FEW PLANTS OF SOME OF THE HYBRID ASTILBES WILL MAKE A FINE SPLASH OF COLOUR IN THE BORDER IN JULY AND AUGUST.

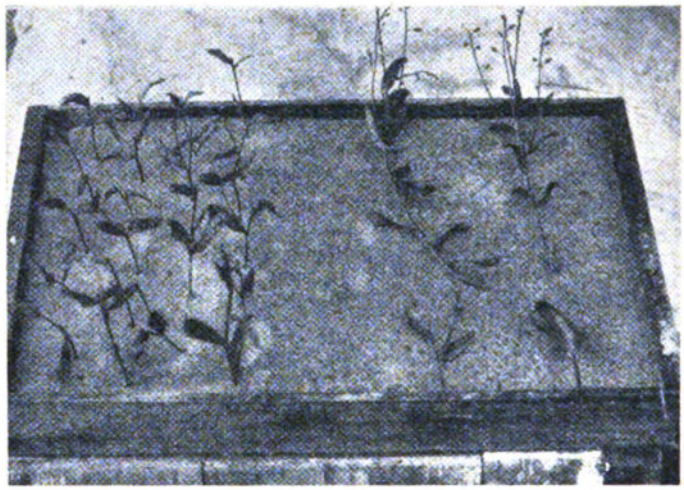
THE BUSY MAN'S PAGE

Propagating Forget-Me-Nots.

Cuttings may be taken now.

WHILE the usual method to obtain a stock of this plant is by sowing seeds in June or July out of doors, or collecting self-sown seedlings, they are very easily increased from cuttings. The cuttings selected should be of fairly firm growths, taken from old plants that have finished flowering, and their length be from 2ins. to 4ins., cutting them beneath a joint or leaf. Trim off a few of the lower leaves also; they often emit roots where the leaves are taken off if the cuttings be of the right type, firm and short-jointed. To receive the cuttings make up a bed of sifted sand of from 2ins. to 3ins. deep in a frame or box. Before putting in the cuttings give the sand a thorough soaking of water and allow it to drain off. See that the sand is level, going over it with a levelling board to ensure this. Make it thoroughly firm, almost hard. Dibble the cuttings into the sand from 1in. to 2ins. apart each way, watering them with a fine-rosed can afterwards to settle them in the sand; then place the sash (or light) over them, keeping them rather close for a week or two until they have calloused and can stand a little ventilation. Always shade them from sunshine until they can stand being fully open. Where only a few dozen plants or so are required, a box or boxes of about 7in. or 8in. in depth will do quite well, following the same method as outlined for the frame and placing sheets of glass over them. Boxes have advantages over frames, as they are much easier to shift about if made of convenient size. They may be placed at the foot of a wall or hedge where they may not require the attention of shading.

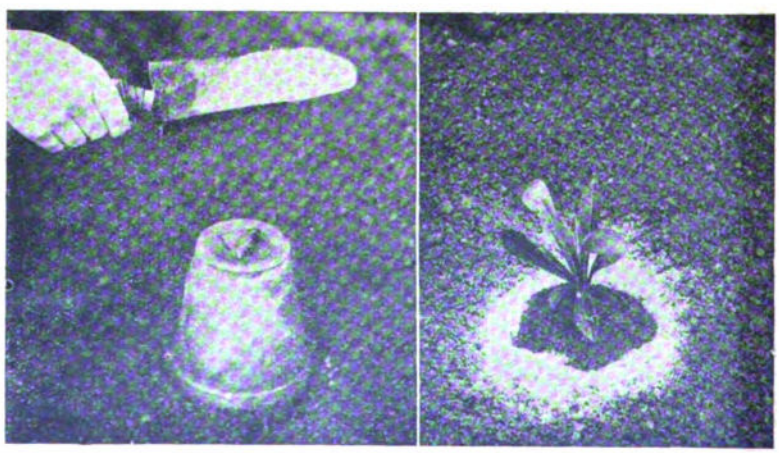
When the plants are rooted and hardened off they may be planted out on a border in nursery lines previous to their final shift out in autumn for beds or borders. Rooting plants from cuttings is the surest means of retaining stock of any particular shade of colour, such as pinks and whites as well as plants of an attractive graceful habit.



CUTTINGS OF FORGET-ME-NOTS INSERTED IN A BOX OF SANDY SOIL.

Slug Cures.

SLUG infested soils are benefited by a good dressing of soil fumigant, like 'Vaporite," "Sterole," and others similar, a few weeks in advance of cropping, the material being lightly dug in with the garden fork. Liquids like cresol, "Clubicide," formalin, ammonia, etc., may also be applied, in this case without digging; the best time to use the liquid is in mild, moist weather in March or early in April. Among growing crops one has got to be very careful, but a few proprietary powders are available; at any rate, one must recognise that these and the more ancient soot, lime, lime and alum, alum alone and barley awns are all alike of little effective use unless repeatedly applied. Still, one must confess that all spring slug cures need repetition, even those new ones that are so effective and so harmless to vegetation. The R.H.S. cure entails the preparation of lime water into each gallon of which is poured a quart of hot water containing ¼lb. aluminium sulphate (commercial quality, about 5d. per lb., not alum). This is quite harmless to seedlings and all plants. Kainit or potash salts, 1½lb., commercial bluestone 1 oz., at 1 oz. per square yard is the Leeds University cure, and a good one; apply at night when slugs are about, over plants and soil. Bran, half a gallon, mixed dry with two teaspoonfuls of Paris Green is good, too, little heaps being laid alongside tasty plants.



PROTECTING PLANTS AGAINST SLUGS.

A dodge for ringing around small plants with lime or soot, especially applicable to the young shoots of beans and peas. The pictures explain themselves.

Biennials and Perennials from Seed, Mid-Summer Treatment.

BIENNIALS are plants which, being raised from seeds in one year, flower and ripen seeds the following year. As some are hardy and ripen their seeds by the month of August, these seeds may be sown forthwith. Others, which ripen their seeds in early autumn, are best harvested and their seeds sown in frames the following spring. Seedlings of such raised last spring under the protection of a frame are sturdy specimens by this time, but if they are neglected about midsummer they will be poor stock and bear only puny flowers next year. It is very important that all these sturdy seedlings be well cared for now. It will, with few exceptions, be inconvenient to plant them in their flowering quarters at present so we should prepare a nursery bed and work the soil in it thoroughly and deeply, adding rotted manure if the soil is poor and then transplant the seedlings about 5ins. apart each way. In dry weather plants in these beds must be watered as carefully as pot plants in a greenhouse, because they do not possess many roots and all of them are very tender, quickly succumbing to drought if it is prolonged. In September all may be finally transplanted, some in tuft form, some with side shoots well developed and all with good balls of soil adhering to their roots.

Perennials must be similarly treated. They are plants that live more than two years, but many of them flower well the second year, a few in the same year in which they are raised if the seeds are sown under glass early in the spring. We may instance the starworts — the Michaelmas daisies — but it is bad policy to attempt to flower seedlings in the same year in which they are raised. Raised in comparatively cool conditions in cold frames the plants make good progress if they are generously treated. These and all seedlings of perennials — delphiniums especially — should be kept growing by affording them ample soil in which to root, because they possess so many roots while quite young, then they will be fine specimens by the month of September when generally the final transplanting may take place. At the present time use the Dutch hoe freely between the rows of plants, not only to keep down weeds, but also to create a dust-mulch, which is very beneficial to the plants during dry weather.

Summer Saladings.

IF the weather is warm and dry, it is well to make successional sowings of salads, because they do not last long in a nice crisp condition. Watering helps materially to prolong their season of crispness.

Lettuces are best sown in drills during July and August, so as to obviate the need for transplanting, which is always a difficult job during hot, dry weather. In any case, lettuces which are grown on in drills without transplanting are generally of a finer quality than those which suffer the check to growth which even the most careful planting out cannot avoid.

When sown in drills, the seedlings can be thinned out after the manner of turnips or a few of the best of the thinnings may be transplanted, if necessary, to augment the supply.

The Australian or golden cress is best for summer. It furnishes a continuous supply, as it can be cut repeatedly. It is one of the most useful of summer saladings when grown in a rich soil. Mustard and plain cress are best for winter use. Sowings of radishes in frames and out of doors may now also be made to meet the season's requirements.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Care of the Town Garden.

JUNE, with its long days of sunshine, is the month of growth. It is also the off-season in the average garden. Spring flowers have finished with a glorious burst of orange wallflowers and gay irises. Annuals sown in the open and many of the roses will not be at their best until the end of the month. Both vegetables and flowers are making ready for the July harvest, but, nevertheless, there is much to do in the garden, and it may be truly said that for the amateur there is no real off-season. There is always something to be done in preparation for the coming months. It does not take a lot of time to keep a garden trim if each piece of work is done at the proper time.

It is important to run the hoe through the clumps of perennial flowers and annuals in the flower border. A few hours with a hoe on a sunny day will save ten times the amount of effort that would be required to kill the same area of weeds if they are allowed to grow until they must be hand-weeded.

Having gone over the whole garden with a hoe, get out the fertiliser tin and give a little dusting round all plants which are in a state of half-growth. By and by the beneficial rain will wash this into the surface soil, and the garden will assume an atmosphere of prosperity. For the small garden the prepared fertilisers are convenient to use, and with these the amount per square yard is usually stated. A golden rule with all concentrated fertilisers is "a little and often," and remember that nitrates, either nitrate of soda or sulphate of ammonia, should not be used too freely in a shady garden. Phosphatic manures, such as bone-meal or superphosphate of lime and potassium sulphate, are the best to use in the shady garden. A suitable dressing would be 3 oz. of superphosphate of lime and 1 oz. of sulphate of potash to each square yard.

Having cleaned the garden of weeds and added fertiliser, the next consideration is to tie and fix stakes to those plants that require support. Clematis and Wichuraiana roses require constant tying to prevent the young shoots from being broken. Where these rise from the base too thickly, thin out the weaker specimens and tie in the remainder.

There is little pruning to be done in the garden except those shrubs that have finished flowering, such as broom and forsythia. I saw a specimen of forsythia the other day with little thin, wiry stems, and its owner was puzzled as to why it did not flower. Inside a ball of matted growth I could see thick, sturdy shoots beginning to show themselves, and I advised immediate pruning so that these young thick growths would grow during the coming summer and make flowering shoots for next season. Fortunately, many of our shrubs do not require much pruning, unless they outgrow their allotted position.

Removing Dead Flowers.

It is important to remember that a few dead flowers on such plants as violas, geum and sweet peas soon check the otherwise free-flowering habit of these plants. It is of first importance to remove these as soon as they are faded. Where lilacs, azaleas and rhododendrons are grown they should also have the dead flowers removed to avoid seed production so that better growth will result for next season's flowers.

Care of the Lawn.

Beyond cutting the grass there is little to do on the lawn except to keep a watch for spreading weeds, such as daisies and dandelions. When quite young these are easily removed with a sharp knife or trowel. Five or ten minutes spent on a small lawn will save untold trouble from weeds.

I am asked to give a few plants that could be grown in a window-box on the side of a road which receives a few hours' direct sunshine each day. The following could be planted now: Petunias (various colours), ivy-leaved geraniums, verbenas and fuchsias. In a small window-box a better effect is obtained by using one, or at the most two kinds of plants. Where two or more kinds are used it is important to remember the colour of the flowers and other surroundings, and to avoid combinations of colour which are not harmonious.

Border Edges.

IF your lawn runs right up to the flower borders, an edging, formal or natural, is not necessary. Different plants can be grown in the border, and even the height of those nearest the grass can vary considerably to break the otherwise flat appearance. But where the border is against a stone walk, uniform green edging of some kind sets off the flowers to advantage. Thrift is one of the best of edgings for this purpose. It is perennially green, grows thickly, but not too tall for the purpose, and can easily be kept within desired limits. When the flowers appear they are of a soft pink, which is most attractive and seldom clashes with any other colours which are in the border. The fact that thrift is seen in gardens in town and suburb, at the seaside, and in the heart of the country, is sufficient proof of its adaptability to conditions of all sorts.

Pillar Roses.

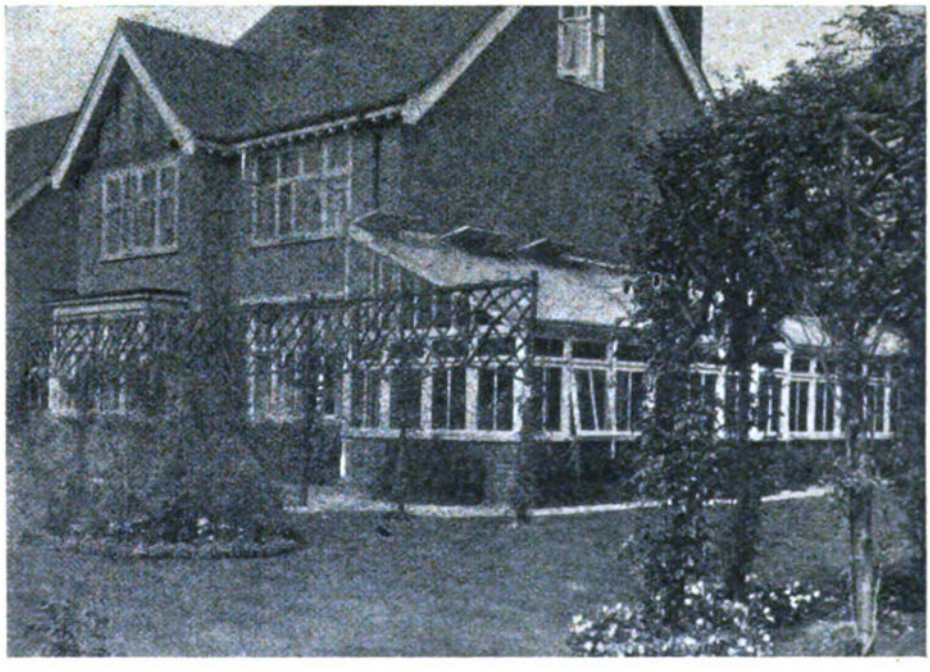
AT the foot of the pillar where roses climb, it is desirable to allow a small space which is not covered by grass or by stone paving. This tiny break in the lawn or pathway can be used to grow a few violas or similar dwarf flowers. Liquid manure can be applied both for the benefit of the roses and also of the violas, and even a surface mulch can be put among these flowers without appearing unsightly, as it would do if it were laid on to a part of the lawn. Retaining a small bed of this kind at the base of the roses also allows air to reach the roots, and so assists the growth of new shoots.

Nearly all plants benefit from liquid manure during the summer, as this is the time when growth is taking place very rapidly. Roses are specially appreciative of assistance in this way, and small and frequent doses should be applied throughout the next two or three months.

Roof Gardens.

ROOF gardens vary considerably as to the amount of sunshine they receive. Frequently, even though the roof at first may receive plenty of sunlight, it is thought desirable to erect high trellis to screen off surrounding chimney tops, and the roof becomes shaded in consequence. In place of carnations and such sun-loving flowers, we have then to select plants that will thrive in the shade. In most cases this also means that more watering must be done, for the shade loving plants are generally also moisture loving, and shallow pans and boxes, such as form the basis of roof gardens, need constant attention if the soil is to remain moist. Violas, calceolarias and tobacco flowers are suitable plants for shady roof gardens, where a plentiful supply of water can be given.

It is a fatal mistake, where sun is lacking, to make up a very rich compost for the plants. Bonemeal is an excellent and slow acting fertiliser, which should be used in preference to leaf mould and animal manures. Shady gardens need lime to counteract the tendency to acidity in the soil.



IN THIS ATTRACTIVE TOWN GARDEN VIOLAS ARE PLANTED IN THE SMALL BEDS WHICH SURROUND THE BASE OF EACH PILLAR ROSE.

The Town Gardening Handbook. — This volume, the official handbook of the London Gardens Guild, is obtainable from all booksellers and newsagents. The price is, cloth covers 2s. 6d., paper covers 1s. 6d. It is the one book for all amateurs who garden in town and suburb.

WORK IN THE FLOWER GARDEN

Garden Operations for June.

PLANTS put out in beds or borders should have been given a good soaking of water at the time, should the soil be dry, the same being repeated at intervals if hot weather and drying winds prevail. The very common practice of giving plants driblets of water daily is by no means an advisable rule to follow, as it merely causes the formation of a few surface roots, which ultimately die. The free thinning out of annuals in proportion to their height should not be neglected. Chrysanthemums and herbaceous plants that require support should be staked. It is important to keep weeds in check among all flowers, by frequent use of the Dutch hoe, and it is of great assistance in promoting healthy plant growth by admitting light and air to the soil and drawing moisture nearer the surface, and greatly adds to a neat and tidy appearance of the garden. A sharp look-out should be kept for green and black fly, and all sucking insects and caterpillars. Do not allow these pests time to establish families on your roses and fruit bushes; give timely spraying with a approved insecticide, using washing soda or ammonium polysulphide for mildew on gooseberries.

During the month seeds of violas, pansies, forget-me-nots and polyanthus may be sown in a moist shaded spot, and a few seeds of double wallflower and Forget-me-not Ruth Fischer, in a box, to be potted up for greenhouse work in winter and spring. Many plants for the rockery may be raised from seed sown now in boxes, such as Alyssum saxatile, æthionema, aubrietia, dianthus, dwarf campanulas, iberis, linum, etc.

In the vegetable quarter, carrots, parsnips, turnips and lettuce should be thinned out, and another sowing made of the latter two for succession. Celery should be planted out on a well manured trench and heavily drenched with water. Cabbage, cauliflower and sprouts should be planted out now; and broccoli, sprouting curled kale and savoys later in the month for spring use.

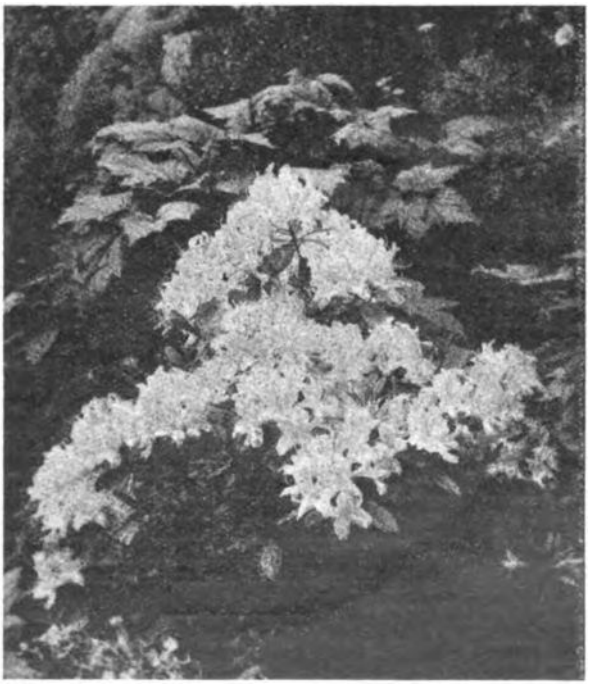
Potatoes that require earthing up should be attended to, previously giving the ground a dressing of a good potato manure, which is usually so compounded as to meet the requirements of the tubers. Soot and wood ashes give good results in place of the manure.

Ground that is to be planted with leeks should now be dug, if this has not already been done. It pays to give the crop liberal and generous treatment in the way of manure, also adding plenty of decayed leaves and bone-meal. Endeavour to make a rich and free root-run for the thick fleshy roots, with plenty of depth. In early districts, ground that has been cleared of early potatoes is sometimes utilised for this crop.

Stake late peas, and keep a watchful eye on all cabbage and other brassica crops for caterpillars, and spray in the evenings with a solution of salt and water should they appear. Dissolve from 1 oz. to 2 oz. of salt in a gallon of water and apply frequently until the pest disappears. —W. G.

A Beautiful Dwarf Rhododendron.

RHODODENDRON AZALEOIDES has long been in cultivation, it being raised over a century ago; but, in spite of this and its unique attractions, it does not appear to be well known in gardens. This is the more surprising when one realises that it is easily obtained and is by no means expensive. Rh. azaleoides is supposed to be a hybrid between an evergreen and a deciduous species, so that it is semi-evergreen in habit. It is a dwarf shrub, only reaching some 3–4ft., but my own specimen, now ten years old, is scarcely 2ft. Notwithstanding this, the flowers and trusses are extraordinarily large, as the illustration shows, and the blooms, which are deliciously scented, are pure white flushed with lilac. Not only does this little rhododendron—so eminently adapted for the small gardener—flower with the greatest abundance, but it does so in July, that is, long after those of most of its kind are over. Rh. azaleoides (syn. Rh. fragrans) does very well in any ordinary lime-free loam which is well drained, and not too stiff but it is always glad of a top-dressing of half-decayed leaves occasionally. There is one more commendable feature about this engaging little shrub, and that is that it is much more easily raised from cuttings than most of its race. Half-ripened shoots of young wood taken with a sharp knife just at the junction with the old and inserted in pots of sand and a little fine leaf-mould will strike readily in a closed frame. This should be done in August or earlier if suitable cuttings are forthcoming.—A. T. J.



RHODODENDRON AZALEOIDES WITH ITS LARGE FLOWER TRUSSES OF PURE WHITE FLUSHED WITH LILAC

Saxifraga moschata.

THE inrush of novelties and the universal thirst for "something new" are responsible for the possibility of our overlooking one of the best of all mossy saxifrages,

THE FREE-FLOWERING S. MOSCHATA IS NEAT AND COMPACT IN GROWTH AND ONE OF THE BEST OF MOSSY SAXIFRAGES.

S. moschata, or "muscoides" of most trade lists. None who knows the real worth of this alpine jewel will ever be without it, but as one of the older ones there may be many who are apt to pass it by. I like S. moschata in all its forms because it is such a good doer, always retaining its neat, compact shape, always mounding over the rocks in a closely woven, clinging carpet of verdure, and it never gets "kicked about" by birds or wind. Then S. moschata blooms regularly every season with the greatest abundance, and its innumerable little flowers on quite short stalks, with which it bristles like pins in a pin-cushion, never fail to attract the most enthusiastic admiration.

S. moschata, which can be planted from pots at any time, likes a fairly cool site with a root run in free, gritty or stony soil through which a little fine leaf-mould has been mixed. It delights to mound over a low rock, as I have suggested, but is really not at all particular, often doing very well on the flat. There are many varieties of this admirable little plant. S. m. atro-purpurea is deservedly a favourite owing to the brilliance of its little blossoms. Fairy, Wild Rose and pygmæa are of the same low and firm cushiony habit, and there are many others. And it is to these in particular, rather than to the looser and larger forms of the S. Rhei type, to which I refer when urging the claims of this most charming and useful mossy saxifrage.—A.

Evergreen Candytufts.

THE perennial or evergreen candytufts (iberis) are among the most useful plants in the garden. The dwarf bushes which they form are green all the year, while the production of flowers over a long season, from the spring until well into the summer, is on a handsome scale. If left undisturbed for two or three years, the perennial candytufts assume a low shrubby habit, in which form they have a quaintness which is distinctively attractive. These plants are admirable for edgings, for spring bedding in

Digitized by Google

association with bulbs, and they also are useful along the margin of a herbaceous border and in the rock garden. All the perennial candytufts flourish in almost any situation, providing this is not too densely shaded. They are not particular, although they flower with the greatest freedom when the ground is on the light side. The perennial candytufts are easily propagated from seeds, cuttings and by division. Seeds may be grown out of doors from March to July; cuttings may be inserted at any time during the summer; while the autumn is a good time to lift and divide old plants. It is worth noting that established plants of the perennial candytufts will often continue in flower throughout the greater part of the year, especially when the winter is mild. The best known of the perennial candytufts is Iberis sempervirens, which has snow white flowers and grows to the height of about a foot; Garrexiana has somewhat larger heads of flowers than the type; Little Gem is a dwarf compact form; Snow Queen is an exceptionally free flowering variety; superba has very large flowers; flore pleno is a double form. Two other species which are worth growing are I. corifolia, which grows a foot or more in height, and I. gibraltarica, a very charming plant producing flowers in winter and spring which are often tinged with a lilac pink shade.

Viola gracilis Clarence Elliott.

THIS little viola has already obtained a high position as a good, free-flowering variety of that valuable species, V. gracilis, from which we have gained a few good plants for the rock garden or front of the border. V. g. Clarence Elliott is not likely to be superseded in a hurry, as it is so floriferous, while its well formed flowers are white and create a good effect wherever planted. That it will flower from April until August is no mean commendation and by dint of a little care in taking off the withered blooms its period of beauty may be still further prolonged. Then it has the true tufted habit which is so highly prized and will soon grow into good tufts for division if this is desired. It is also quite hardy and perennial and will thrive in almost any soil.—S. ARNOTT.

Primula Forrestii.

THIS has been one of the most interesting primulas in bloom during the month of May, and it may be compared to a glorified cowslip, although, perhaps, the flower stalks are not quite so long. It is a native of the high Alps of Yunnan, from whence it was introduced by Forrest some years ago. I am afraid it has not lived up to its reputation in being a good grower under all conditions. However, a certain amount of success can be obtained and like most other members of this delightful family, frequent propagation by seeds is advisable. These are best sown directly they are ripe and the seedlings should pass the winter in a cold frame, free from excessive damp, then they are transferred to their flowering quarters about April.

It should be grown in pockets and in high and dry crevices, where it is well drained, and although it is said to enjoy plenty of sunshine, I have found a position facing east to suit it admirably. Here examples have lived for several years, producing their spikes of golden yellow flowers, which pass into rich orange, these being in clusters and about the size of a shilling. No protection has been given and another plant, a chance seedling, has been growing freely for several years on a well drained slope of the rock garden. This primula has a delightful scent, both flowers, stem and leaves, but it is not very pronounced in the two latter. The leaves are crinkled and oblong heart-shaped, the whole plant being quite attractive even when not in blossom. When planting it should be remembered that P. Forrestii is a lime-loving species, and that excessive damp is its greatest enemy. The former can be supplied in the form of old mortar rubble mixed with the soil, and in most rock gardens suitable spots can be found where efficient drainage can be secured. In P. rufa we have a close ally of P. Forrestii, and so far I have not noticed any difference in its cultural requirements.—T. W. B.

A WELL CARED FOR SMALL GARDEN.

Here the roses on the arches have had their new growths regularly tied in so that they are always neat in appearance.

Summer Treatment of Chrysanthemums in Pots.

FROM the present time until the end of August, plants that are well treated will grow rapidly. After the end of August, few flower buds are formed, active growth of branch lessens considerably and the wood and leaves already formed begin to ripen quickly. This is the proper condition of a well managed plant. Of course, a certain amount of ripening goes on throughout the summer months and to further such conditions of growth we must see that the plants, now, are well arranged in a sheltered, but sunny position outside. They must not be overcrowded. The rows of plants should be, if convenient, due north and south, so that they will get the maximum amount of sunshine. The tallest growing varieties should be at the north end of each row and the dwarf ones at the southern end. The rows should be, approximately, 4ft. apart and the plants in the rows 18ins. asunder. The final potting of specimen plants and those grown for the production of exhibition blooms, should be completed as soon as possible. The final potting of those intended for late flowering should be completed by the end of June. Frequently, the inexperienced cultivator will pinch, or stop, these late-flowering plants well on in the month of July, thinking that by doing so they will reap a particularly late harvest of bloom. It is a mistake to stop the plants very late, as the resultant flowers often fail to develop well, coming one-sided, often bearing a few straggling flower petals only. Do not stop the plants after June. Resultant crown and terminal buds after this date will develop in a proper way.

The staking of the plants should be done now so that the ends of the stakes can be driven into the new soil in the pots, thus avoiding injury to the roots. When newly potted plants require water, apply sufficient to moisten the whole of the soil in each pot thoroughly and then allow the soil to get fairly dry again before applying more water. It is a mistake to keep the new compost in a sodden state. Later on, when the soil is full of roots, water will be needed much more frequently.

Keep the stems loosely tied against strong winds; watch the points of growth and free them from green and black aphides by the judicious use of tobacco powder and syringing. Watch for the frog hopper grub and kill it in its froth—the white juices of the plant; also, scatter fresh soot on the ground weekly near the plants to drive away the fly of the leaf-mining maggot. An occasional light spraying of the leaves with clear soot water will be beneficial in this direction, too.—G.

A BEAUTIFUL ARRAY OF SUMMER FLOWERS.

To obtain an attractive border such as this one, delphiniums, campanulas, and other tall perennials should be staked securely at once.

The Herbaceous Border.

PLANTS in the border are now making rapid progress and staking demands attention. In doing this aim at preserving the natural appearance of the plants. Those of branching habit are best supported with bushy pea sticks trimmed to suitable lengths, while plants like delphiniums should have each stem secured to a strong bamboo cane or straight stake. The removal of dead blossoms from plants that have finished flowering—heuchera, doronicum, etc.—should receive attention early. Water when necessary. Hoeing should be a regular operation among all plants, and a mulch of manure will be of great assistance to growth in light sandy soils, and elsewhere to those that are expected to give a second crop of blossom, to which class delphiniums and pyrethrums belong.—J. C.

THE SUMMER TREATMENT OF GREENHOUSE PLANTS

Through intervention of other matters and pressing work to be done among plants coming into bloom in the garden, there is sometimes a temptation to pay less regard to those in the greenhouse, the frames and elsewhere, which, if rightly treated and well looked after now, will ensure beautiful blossoms in the dull days of the year.

WHETHER the gardener be a professional or an amateur with limited time and space for gardening, with possibly one greenhouse, the same rule operates for both.

It is, that, whatever the season may be, thought and consideration must be given not only to subjects under culture that engage special attention for the time being, but plans must be in hand for preparation of ground, for successive crops and the upbringing of plants for future display. In a word, the work of the gardener is never quite finished. There is no finality in gardening; you never come to an end of it, or of its possibilities, except in the sense that the end of to-day's work is the beginning of to-morrow's.

Plants for Autumn and Winter Blooming may be divided into two distinct classes, *viz.*, (1) those of a hard-wooded, and (2) those of a soft-wooded character. In the first named we have azaleas, camellias, heaths, boronias, mostly lovers of peat, in which they are nearly always grown, and that substance being of a close, retentive nature, there is always a danger lest they should be starved for want of sufficient moisture. From now onwards for a few months many of them will be deposited in frames out of doors, and it is here where the mischief is not infrequently brought about. Nominally these structures are called cold frames. In reality they are nothing of the kind, as, in many instances, frames are quartered in a garden in a south position where they can get every gleam of sunlight and, whether the lights are kept on or not, the very position is reverse to that of coolness.

Importance is often placed on ripening of wood, and with some plants this is very essential, but with hard-wooded subjects it may be achieved at the expense of starvation. There is such a thing as over-doing "the sunny position," and overlooking the need for coolness at the roots, and, in the case of the plants mentioned, a thorough soaking of water when it is needful to water them. Besides this, it is a wise thing so to arrange matters that frames for reception of *any kind* of plants which are being prepared for winter blooming, shall have coolness for part of the day, as well as sun, and thus, in some degree, at least, merit the term "cold frame." The north side of the garden, where the sun leaves it for part of the day, is the place where plants in preparation should be located. There will be times, of course, when the lights can be taken off altogether, to the advantage of the plants. They should be stood on beds of ashes; those from the greenhouse fire-hole, if others cannot be had, sufficing; the idea being to conserve moisture about the roots. Each plant should stand clear of its neighbour and opportunity ought to be taken to syringe them when the sun if off, several times a week.

Plants of a Soft-wooded Character.—These consist of such things as primulas, cinerarias, zonal pelargoniums, cyclamens, which are grown in a lighter and more friable compost. They, too, are best served when placed out of the way of the sun for a few hours every day. It is when exposed to heat all the time that they become weak and debilitated, lose their robustness and so are badly equipped for flowering. Steady growth in their case is very essential and this can only be achieved and maintained when plants are grown under temperate conditions and when care is given to shade so that they can recuperate. Especially should attention be given to the location of the frame in a time of drought, and to regularity in watering. Plants of the second character will also benefit by being given weak applications of liquid manure occasionally. During the summer it will be found that buds of primulas and zonals often make their appearance, but these should be picked off, the idea being to build up the plants, promote growth and so have them in the pink of perfection by the time it is necessary to house them in September. The grower of chrysanthemums, while appreciating sun from morning to night to enable wood to ripen, must be prepared to afford water—which may mean twice a day in the hottest weather, and he, too, will take the precaution to stand the pots on ashes and so save a little labour. For the plants in smaller pots mentioned, whose vitality can soon be depleted by abnormal heat, let us see that in their case they will be able to enjoy that coolness which is so essential to them. W. F.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

APROPOS of Suttons' exhibit at Chelsea and the beautifully coloured reproduction of salpiglossis on the cover of THE GARDEN, I am surprised to learn both from nurserymen and amateur gardeners, that this attractive half-hardy annual does not transplant well and is difficult to grow in Scotland. Each and all expressed regret that such should be the case, as they recognised its decorative value in bed and border. Personally, I have had no experience in raising salpiglossis from seed, but I have been in the habit of obtaining a few dozen plants annually from Glencarse Nursery and strange as it may appear, they have flowered successfully in Ayrshire with no more care or attention than what is usually given to any other half-hardy subject. They respond readily to genial conditions and for that reason they should not be transplanted before the first or second week of June. A bed of salpiglossis carpeted by sweet alyssum gives relief to the dark coloured specimens of the former and makes an exquisite picture in August.

A little space should be d voted in every garden to the raising of the more popular plants for summer salads, as the home-grown examples are always fresher and crisper than the ordinary vegetables purchased in shops. Tomatoes and lettuces are the principal constituents of the salad bowl, but although the former are only grown out of doors in favoured situations in Scotland and even then the fruit seldom attains the quality of the crops raised under glass, there is no reason why the amateur with a small bit of ground at his disposal, should not provide his own lettuce and also radish, mustard and cress to add nee ed variety to a salad in hot weather. A large quantity of either is not desirable. The object should be to sow the seed in small quantities at intervals and thus provide a continuous supply throughout the summer. Lettuce that are undisturbed mature quicker than the transplanted thinnings, but the check which accompanies the change of situation may be minimised by shifting the seedlings during an early stage of growth. This is where many amateurs err. When transplanted in an advanced condition, the tall leaves collapse readily and when exposed to the heat of the sun they frequently wither beyond recovery. An endeavour should, therefore, be made to shift lettuce in dull or showery weather when the soil is moist and, if at all possible, give them a place between the rows of tall growing peas, where they will obtain partial shade. Moisture is essential to rapid growth, and frequent soakings are needed in dry weather, for if the soil becomes dry at the roots the plants will run to seed prematurely. The cabbage type blanch naturally, but nearly all the cos varieties require to be tied near the top with raffia.

The art of weeding should be studied by every gardener. In his monumental work, Mr. John Weathers specifies 106 kinds of weeds which are to be found in different soils and of that number thirty-three are constantly forcing their way into cultivated garden ground. With five exceptions these belong to a type that may take years to eradicate once they are allowed to get anything like a firm foothold, and the lesson to be learned from the constant struggle thus going on in the soil is that the weeds must be destroyed and their places filled with more desirable tenants. When thoroughly done, hand weeding is the most effective method of clearing flower and vegetable beds and while it is one of the most exacting jobs that one can undertake in summer, an occasional hour spent in the evening at this time of the year will save a lot of time and labour in future. The frequent use of the hoe is helpful in keeping down surface weeds, but it only removes the top of deep rooted weeds and of the perennial type and in the case of weeds growing among seedlings, there is no alternative to hand weeding. It is in the open spaces that the hoe can be most successfully operated and once the young surface weeds of the annual species are uprooted, they soon wither from exposure to the sun. One of the most common mistakes is to begin weeding late in the season. Never postpone the work until June, when the neglected weeds of May have given the ground a verdant covering and robbed the soil of food and moisture, and do not be misled by the idea that weeds that are allowed to remain in the soil in autumn will be killed by winter frosts, because they will remain to encumber the ground and, being seeding time, 'One year's seeding means seven years' weeding." Had hand weeding been thoroughly done in early summer, there would have been fewer weeds left to seed in autumn, the plants would have benefited, and the tidy and clean appearance of the garden would have contributed to the pleasure of the household. While the hoe is most effective in dry weather, the best time for hand weeding is after rain, when the soil is moist. Deep rooted weeds are difficult to remove when the ground is hard and caked and when a portion of the roots remain in the soil they usually grow again. In these circumstances a hand fork is of valuable assistance and if the weeds are firmly gripped at the base and given a slight twist, they can be extracted by the root. Never allow weeds to be on the surface—the only safe way is to burn them or consign them to the rubbish heap. ST. MUNGO.

REMEDIES FOR INSECT PESTS

Some timely hints on how to deal with them. Be wise in time. Destroy the early broods. Save later trouble.

DURING the summer months insect pests cause much worry in the garden and on the allotment. Seedlings resulting from early spring sowing may have been making most gratifying progress when suddenly insect pests begin to appear. The whole secret of success in dealing with such is in making an early start and doing the treatment in a thorough manner.

Gooseberry Pests.

A good instance is that of the gooseberry caterpillars or larvæ of magpie moth. These are not difficult to eradicate if measures are taken at once. In certain districts these caterpillars annually defoliate the gooseberry bushes. The larvæ when first appearing in spring are quite small and brownish in colour. These larvæ have been hibernating during winter. Later they assume the familiar black and white, magpie colour scheme from which they received their name. If dealt with promptly they may be destroyed once and for all. If these measures are not taken the caterpillars will return. Hand-picking is slow, but very effective. The caterpillars may be dropped into strong salt water or oil. When the fruit is swelling it is better to avoid insecticides. However, these may be applied double strength afterwards. Nicotine washes or even soap and water are usually effective. A good plan is to syringe the bushes with clear water, using a powerful syringe. The force of the water dislodges the larvæ, which may be picked up or dug into the soil.

Cabbage White Butterflies.

The cabbage white butterflies are another good example. As these pests are double brooded, it is obvious that if the first caterpillars are destroyed, later plagues may be prevented. As soon as the butterflies are noticed a search must be made on the plants. This will reveal groups of yellow eggs. These may be easily destroyed. Later the small caterpillars may be hand-picked, and in this way a serious attack may be prevented. If gardeners were to co-operate in this matter it would be much easier to be rid of pests. Many caterpillars may be killed by syringing the plants with salt water. Use 2oz. of common salt to the gallon. An old idea practised by many cottage gardeners after picking the caterpillars by hand, is to throw fine, dry dust on to the plants. This is dashed into the heart of the plants. The plants will grow cleaner and free from the pest. Each female butterfly killed now may mean thousands of larvæ later in the year. The plants may also be sprayed with soap and water, or soot and lime dusted on the plants while damp. No matter what preventive is used, it must be in the early stages of the insect's life. More difficulty will be experienced in destroying the larger larvæ.

One other point must be noted, that is to keep a look-out for the small yellow cocoons so often found near dead caterpillars. These are the pupæ of the ichneumon flies. They live on the internal parts of the cabbage caterpillars, only coming out to pupate. They must be preserved as they are valuable allies of the gardener in his fight against the many pests which beset his path.

Wasps.

In districts where the wasps did much damage last year it will be advisable to destroy all the queen wasps that are found. It is stated by entomologists that in the early part of the year wasps destroy many noxious pests. A little observation will prove that this is to a great extent true. However, it is usually agreed that if all the queen wasps that are easy to get be killed, enough will remain to carry on the alleged good work. Where the pest has been numerous it is advisable to fix traps for them at once. The simplest is a flower pot raised some few inches by stones, a glass jar being placed on top of this. The trap is baited with treacle, the wasps fly under the inverted flower pot after the sweets inside. They naturally fly upwards and are imprisoned.

Green Fly, Timely Advice.

There are many effective remedies to be obtained for green fly on roses and the amateur will be wise if in this matter he acts in good time. Most are very reliable, giving little trouble in preparation and application. The thing is to use the insecticide before the pests have time to increase greatly and afterwards spray with regularity.

Turnip Flea Beetle.

Other prominent pests of the present time include the turnip flea beetle, the carrot fly, the onion fly and the celery fly. The turnip flea beetle furnishes a good illustration of the point of my notes. These insects hibernate in the winter, coming out in early spring to lay eggs on cruciferous weeds, *i.e.*, charlock, shepherd's purse, etc. The beetle itself is no more than one twelfth of an inch in length. It is capable of making long flea-like leaps, hence its name. The grubs tunnel in the leaves of cabbages, etc. There are many generations in a season. The most critical period in the life of any cruciferous plant is until it gets into rough leaf, hence the importance of taking the first batch of pests in hand. Careful eradication of cruciferous weeds is of great importance. These weeds enable the pest to feed and breed before the garden plants are out. Application of soot, lime, or both, or even to dust the young plants with road dust while wet with dew, is good. Boards placed about coated with tar form good traps for the beetles.

Carrot Fly.

The carrot fly grubs bore into the roots and throw up yellow dust, hence the name carrot rust. As in the case of the turnip beetle there are many generations annually. All plants with yellow leaves should be destroyed. Early thinning is advisable. The smell of the plants when disturbed attracts the fly. Therefore it is wise to treat the ground with paraffin after thinning. Soot and lime scattered on the plants are good. The following is given by a great authority: To a barrow of sawdust add one gallon of spirits of tar. This is mixed in the soil at the time of sowing. For all these pests soot and lime are useful. In addition to keeping the pests away, it encourages the plants into robust growth, the fact of which helps them to withstand the attacks of pests. The great point is to anticipate the attacks of pests, and destroy the first broods.—T. H. H.

GROWING CUCUMBERS IN FRAMES

THE value of the ordinary garden frame as a means of procuring a supply of home-grown cucumbers is well known, but few beginners obtain the best results possible by this method. The cause is not usually far to seek—they imperfectly understand the requirements of this crop, and so do not give it the necessary conditions to produce a first-class crop.

A good, well made hot-bed is essential, and this cannot be successfully dispensed with even if the frame is heated with hot-water pipes. Long strawy stable manure and leaves are the best substances from which to make the hot-bed and three parts of the latter (by bulk) to one of the former are about the correct proportions in which they should be mixed. These materials should be gathered together and turned over thoroughly several times at intervals of two or three days before making up the bed. Should any part of it be decidedly dry, it should be damped over as it is turned, but on no account should a state of soddenness be approached.

The size of the bed will depend, of course, upon the dimensions of the frame to be used, but it must be sufficiently large to allow a margin of 2½ft. or 3ft. all round the frame. First of all, mark the corners of the hot-bed-to-be by driving four stakes into the ground, then proceed to place the fermenting material down in layers, carefully treading each layer very firm as the work proceeds. If this is not properly attended to the bed does not settle down evenly and the heat produced is not uniform throughout. A thickness of from 3ft. to 4ft. will be sufficient—the bed to be a little higher at the back than at the front. A sheltered spot, facing south, should be chosen for the construction of the hot-bed.

The frame may be placed in position as soon as the bed is completed, but do not be in too much of a hurry to set out the young plants; rather wait until the bed has settled down and the temperature has just commenced to decline.

The compost in which to plant may consist of good fibrous loam, leaf-mould, sand, and a little rotted horse manure, mixed in such proportions that the whole forms an open porous medium through which the roots will quickly permeate. Do not use too much in the first instance, otherwise it is apt to become sour before the roots enter it—a bucketful to each plant will be sufficient, and more may be added by means of repeated top-dressings as may be necessary. An important point is to place the soil in position some days prior to planting, in order that it may become thoroughly warmed through.

Obtain strong, sturdy, pot-grown plants which are well rooted but not pot-bound; see that they are sufficiently hardened off prior to transferring them to the frame. Choose a spell of warm weather in which to perform this latter operation. Two plants to each 6ft. by 3ft. light will prove ample. Caution will be necessary with regard to watering at first, but the soil must not be allowed to become dry. When the weather is bright, syringe freely and frequently, to promote a moist "growing" atmosphere and admit a little air; but great caution must be exercised in doing this if cold winds prevail, as they so often do at the beginning of the summer. Syringe over, and close the frames up early in the afternoons, so that full advantage is taken of all sun heat.

As the tiny white roots appear on the surface more compost must be added, a thickness of 2ins. or 3ins. being sufficient at one time.

Weak growths will require thinning out occasionally, and all growths other than those required as "leaders" to fill the allotted space may be stopped beyond the second leaf. The middle of the day, when the weather is warm, is the best time to attend to these details without causing the plants to suffer a check. Remove any yellowing foliage or leaves which are jammed against the glass, and water freely with tepid water when the plants are in active growth. During cold weather cover the frames up each night with mats, sacks or other protecting material. Cut the fruits while young and tender, and do not allow too many to set on one plant. When the plants are well established, weekly applications of dilute manure water will prove very helpful.—T. H. E.

WHAT OUR READERS SAY

SEA LAVENDER.

SIR,—From the description given by "T. H. E.," the plant mentioned (THE GARDEN, March 19th, page 181) is not Statice latifolia *Sm.*, but a garden form of S. limonium. The "shining more or less evergreen leaves" rule out true S. latifolia, which possesses leaves which die down in the winter and are densely covered with beautiful stellate pubescence; this also clothes the stem and branches. Its flowers are considerably smaller than those of S. limonium, but for all that it makes a very beautiful garden plant. Boissier placed this species in a different section from S. limonium on account of its five-lobed calyx, more hyaline bracts, etc., whereas the latter possesses a calyx sub-ten-lobed, bracts more herbaceous, etc.—C. E. SALMON, *Reigate*.

CODLIN MOTH.

An appeal to amateur growers.

SIR,—The small maggot which is found in apples is the larvæ of the codlin moth, and the damage it does is very considerable throughout the country. When, however, there is a very short crop or total failure the numbers of the moth must be greatly reduced, having no homes to go to. As far as I have seen this year there are very few eggs about, and it would be of the greatest value if amateur fruit growers would look over their young fruit and gather and burn at once any which show signs of attack. We should thus catch the moth when its numbers are few and reduce very considerably the possibilities of attack next year. The caterpillar enters usually at the eye, and a small hole will be found from which the brown powdery frass is exuding. These are the affected fruits, which should be removed and immediately destroyed. As the thinning of fruits should now be attended to, I send this note to suggest that good work in pest prevention may be accomplished at the same moment.—EDWARD A. BUNYARD, *Maidstone*.

GARDENING TOOLS.

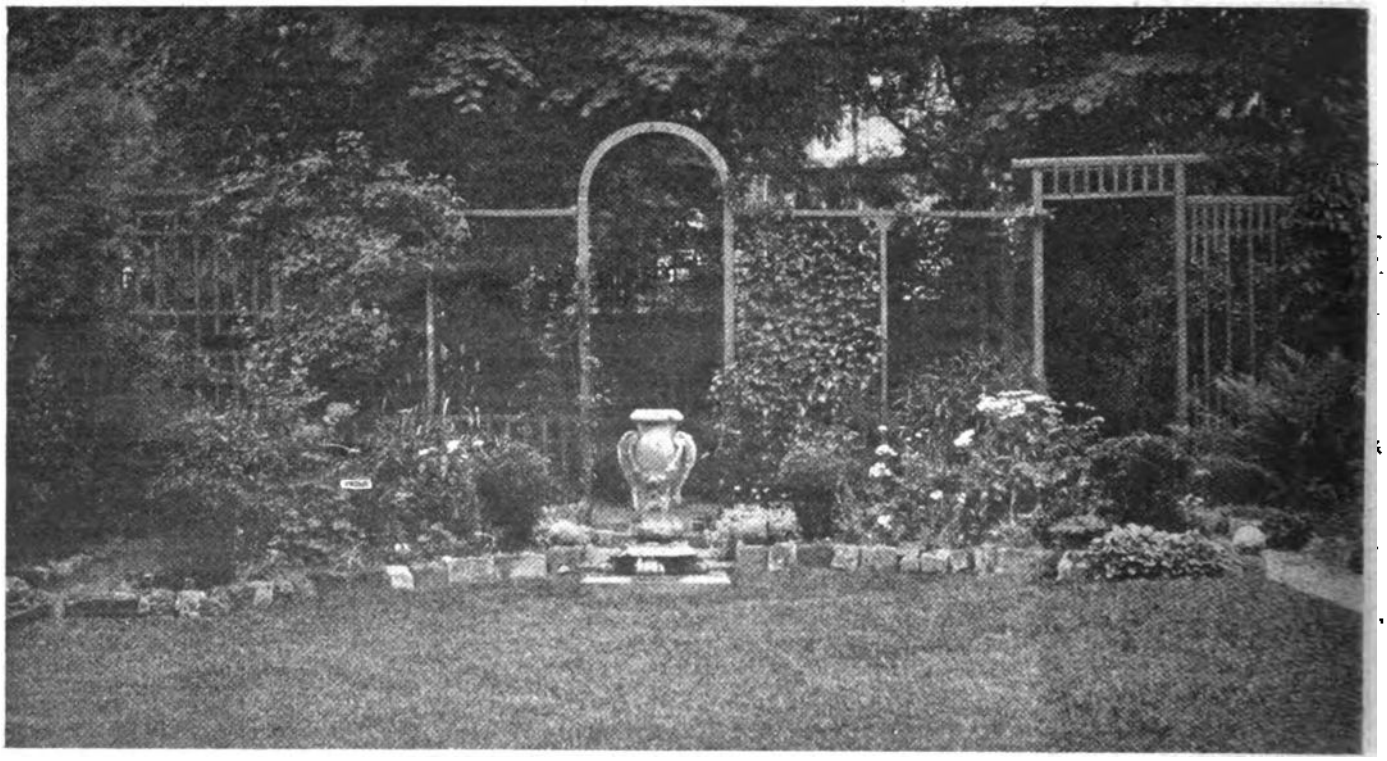
SIR,—You have recently published an interesting series of articles on garden tools. May I add to the list? The gardener very often desires to remove a bulb or a tap-rooting plant without disturbing its immediate neighbours. For plants of moderate size not too deeply rooted an old kitchen or carving fork has its uses. For larger specimens a potato fork or fairly close-pronged garden fork that has been worn down by much garden work is the very implement if, instead of being thrown away, the outside prongs are filed off or sawn off with a hack saw, leaving a two-pronged digging implement. These two hints will be of no use to those who have read Mr. Bowles on the subject of garden tools, but as his book that deals with this is now out of print and therefore not universally available, I mention them.

Recently, like thousands of others, I visited the Chelsea Show. There I had some talk with a friend, a working gardener, who said to me: "Sir, it's a funny thing, I've been round the Show and have not seen a single wheelbarrow I should care to use. They don't make 'em nowadays. All the weight comes on your arms, they are bad to tip, and the bolts are nearly all driven through the woodwork, so that the stays, instead of making the barrow stronger, make them weaker." In consequence of his remarks, I had a look round and, sure enough, his strictures appeared to be not inaccurate.

It should, I submit, be easy for anyone with an elementary knowledge of dynamics to design a standard wheelbarrow so that, while guaranteeing a maximum load, ease of filling, ease of tipping and strength, the weight when full should rest on the point of balance rather than on the arms and shoulders of the person operating the barrow. Can the horticultural sundriesmen be persuaded that such a labour-saving appliance would be popular and useful?—C. J.

OUR PHOTOGRAPHIC COMPETITION

Some of our competitors seem to be under the impression that the photographs which they submit must of necessity be taken in their own gardens. This is by no means essential. As will be seen from time to time, awards are not so confined. There are beautiful and interesting garden pictures to be found all over the country, in public parks, in the gardens of friends, in wayside cottage gardens, as well as in those of more imposing character, and photographs of these are just as acceptable and likely to be instructive and interesting to other garden lovers. For these reasons they are equally as welcome as those taken in the particular garden with which the competitor is associated, though in the latter case opportunity is afforded of intimate notes of personal experience which in themselves may help other readers.



This photograph serves to show the advantage of trellis work in the garden. It is employed to cut off a part of the garden situated under the trees and which affords a shady retreat in the hot weather. The sundial, minus the dial, which is present in the picture, is reputed to be about 200 years old. The design gives an air of spaciousness to the garden, which is on the outskirts of the town. The Guinea Photograph, sent by MR. A. STEEL, *57, Cecile Park, Hornsey, N.8.*

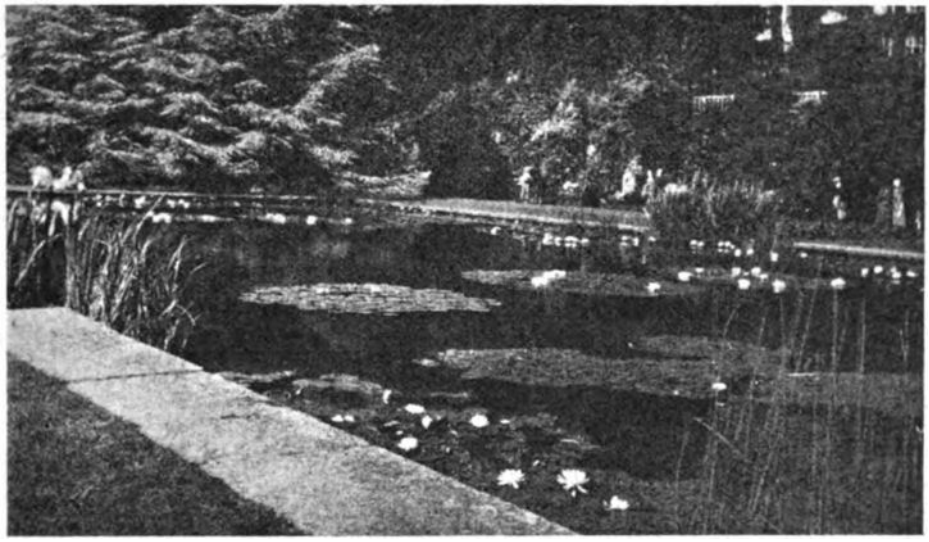
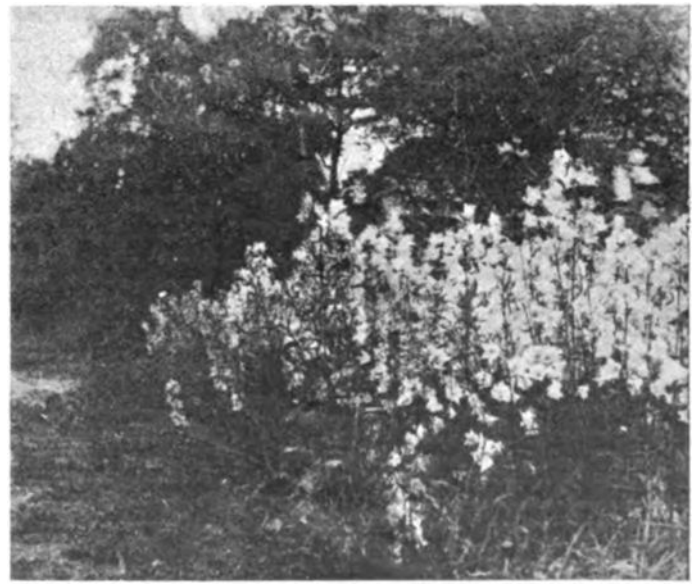
This was formerly a very poor, narrow border in front of a low shed. I widened it considerably and made a brick path. This photograph taken during the second summer of the border shows its effective masses of phlox, King Edward VII daisy, Japanese anemone and an edging of white pinks, broken by masses of yellow violas, gaillardias and poppies.—MRS. C. HARRISON, *Malvern, Worcester.* Award of 5s.

This picture of my lily pond, was taken only three weeks ago. The pond is surrounded by a red brick wall, in which forget-me-nots are growing. These look most decorative. The lilies have not yet opened fully, but in another week or so they will be at their best. A number of varieties are grown, including white and shades of soft pinks and reds.—MRS. K. CLARKE, *Rye.* Award of 5s.



This photograph shows part of the water lily tank on the lily terrace in the gardens at Bodnant. Many hybrid water lilies are grown, showing a wide colour range. In June a thousand blooms have been counted open at one time. The cedars in the background were both planted in 1876.—MISS K. M. DICKINSON, *Hull.* Award of 5s.

Azalea *rosæflora is, perhaps, the best of all the miniature azaleas. Its double rosette flowers are of an attractive shade of salmon pink. It is some twenty-five years old and* 18*ins. high.* —MR. C. NIPPARD, *Bournemouth West.* Award of 5s.



A clump of Campanula persicifolia planted at the edge of a copse in my wild garden looks most effective. It is a first-rate plant for border planting also. MR. HARRISON, *Cheshunt, Herts.* Award of 5s.

THE FRUIT AND KITCHEN GARDEN

Present Work in the Amateur's Vinery.

JUNE is an important period with vines which were started in a slight heat in March; these would flower at the latter end of May and during the present month thinning will require attention. To the experienced cultivator this is a comparatively easy task, for his practised eye tells him which berries to remove directly he sees the bunch, and he forthwith carries out the task without mishap. But the amateur, and more especially the beginner at grape growing, is in a different position and he must exercise a good deal of care if he is to thin out his crop as it should be done. The novice must not attempt to remove all the surplus berries at once, it is far safer to cut out a few and then go over the bunches again about ten days later. It is a good plan to practice thinning in the first instance on a few of the surplus bunches which have to be cut away and then, when a start is made on the thinning proper, commence with the smallest bunches.

The operator must provide himself with a clean, bright pair of special grape scissors and a small notched stick with which to steady the bunch. When thinning, the following points must be borne in mind:

1. Take care not to touch the berries with the hands, hair or cap, as this causes rusty coloured markings on the berries later on.

2. First cut away the small seedless berries, commencing at the bottom of each bunch and the point of each side branch and working to the top of the bunch.

3. On no account cut away the central berry of the three which form each point, and in the case of varieties with long footstalks, all three may be retained.

4. Cut away berries turning inwards.

5. The lower part of the bunch should be thinned more severely than the top or shoulders, and late keeping varieties such as Black Alicante, require more berries removing from the centre than do early varieties, otherwise the inside berries are liable to decay during the autumn.

6. When thinning out varieties known to be shy setters, such as Muscat of Alexandria, do not cut away any but the seedless berries until it is obvious that more berries have set than there is room for.

After thinning is completed the borders should be thoroughly soaked with water at the same temperature as the house, and a few days afterwards a good soaking with manure water will be beneficial, this to be followed by a second dose of manure water after an interval of ten days. Maintain a moist atmosphere by frequently damping the paths and borders and always damp down at closing time. On dull, cool days keep a little heat in the pipes. From mid-June onwards it is advisable to put about 1in. of top ventilation on the vinery about 9 or 10 o'clock in the evening, and early next morning this amount should be increased, otherwise scalding will take place.—T. H. E.

Now is the Time to Earth-up the Potatoes.

THE earthing up of potatoes is one of the simplest of garden operations, but there is more in this method of treating the growing crop than some growers imagine. It may be as well to explain for the benefit of the uninitiated some of the benefits to be derived by drawing up the soil towards the plant and forming a ridge or drill. The runners or stolens to which the tubers are attached are produced near the surface of the ground, and it is therefore necessary to provide a covering of soil that will prevent exposure to the light and cause the potatoes to turn green, a condition that makes them unfit for table use. Earthing up also supports the haulm, while the sloping sides of the ridge are useful in running off heavy rains, thus avoiding an excess of moisture, which in certain soils creates conditions favourable to the outbreak and spread of disease. The plants should be earthed up before the stolens are formed and while that stage of growth varies according to the type, gardeners are generally guided by the height of the foliage, which should not exceed 6ins. In drawing up the soil on either side of the row, care must be taken not to injure the roots with the hoe, and the sloping sides of the ridge should have a slight hollow at the apex. Preparatory to the actual work of earthing up, a little time may be profitably spent in forking the ground between the rows and removing the weeds which, if allowed to remain, are difficult to eradicate later on when the foliage has fully developed. If the soil was enriched with organic manure in winter or spring, a light surface dressing of sulphate of ammonia at the rate of 1 oz. to a running yard has a beneficial effect on the weight of the crop when applied at the hoeing season.

Broccoli for Winter: Some Seeds to Sow for Succession.

AS many plants as available space permits should be planted out in June. The soil is warm and when rain comes the newly planted stock soon becomes established. The soil for them should be firm and moderately rich. I am not in favour of planting broccoli in very poor soil with a view to obtaining firm growths which will withstand severe winter weather, as usually such plants when they have passed through the winter safely, yield only indifferent hearts or curds and the latter are open and mostly discoloured. Have a very firm rooting medium and, if moderately rich, the plants in it will make rapid progress during July, August and September, and become very fine specimens by the early part of November, possessing firm stems, from which large, compact curds will come in due course. The plants will have practically exhausted the nutriment in the soil by the end of the autumn. If such specimens are earthed up in August, the stems just below the lowest leaves will be protected, as it is this portion of the plant that suffers when severe frosts come. These hints apply to Brussels sprouts for spring use, too; with the exception of the earthing, which may be done, but, of course, the plants will grow much higher than the ridge of soil, and their constitution is different, too. I strongly advise readers to plant three varieties of broccoli now, one for mid-winter, one for March and April and one for May and June use. For succession sow a few seeds now of carrots, endive, lettuce, peas, dwarf beans, turnips and radishes, and broadcast pickling onions. Early maturing varieties should be sown.—G. G.

Fruit Trees on Walls.

ALTHOUGH fruit trees, trained on walls are more sheltered than those grown in the open quarters of orchard and garden, they are generally found to be more soiled and more liable to attack by insects. In the open the heavy rains wash the leaves and branches, whereas the walls prevent all such natural washings, except on one side, and that only when the wind and rain come in the right direction. If the cultivator possesses a garden engine or hand pump he should make good use of it at least once a week during June, July and the early part of August. Failing the garden engine, use the hand syringe with as much force as possible, directing the spray sideways to wash the under sides of the leaves. The border soil, too, is often found to be much drier near walls than in the open border and a thorough soaking of the soil to a distance of at least 3ft. from the wall will be highly beneficial. Directly stone fruits, such as apricots, plums and cherries have stoned satisfactorily, follow an application of clear water with one of diluted liquid manure and also apply a light surface mulch to all borders facing due south, so that the moisture will be conserved and the roots kept cool. All retained young shoots should be tied in now, as if left too long untied they become too stiff to be bent to the wires without breaking. Furthermore, these young shoots prevent the sun's rays reaching the fruits if they are not neatly tied in. Stop lateral shoots and pinch out sub-laterals where they may cause undue crowding.—HANTS.

Birds and Soft Fruit.

UNLESS some precautions are taken, birds are likely to do a great deal of damage to the soft fruits. The attacks are much more severe in a dry season, when large numbers of fruits are spoiled by the birds, which are probably suffering from thirst. It is worth recalling that the attentions of the birds may largely be diverted from the fruit if pans of water are placed about the garden. A remarkable proof of the value of this plan was seen by the writer last season, in connection with some cherry trees. Several saucers of water were placed round about the trunks and it was noticed that the blackbirds, after taking a drink, left the fruit alone to a very large extent. Formerly the birds had taken a very heavy toll of the crop indeed. Where birds are present in large numbers this plan should not take the place of other preventive measures. Sparrows in particular will often attack fruits out of sheer mischief, and to be on the safe side nets must be employed. Tie these over bushes, or peg down on to strawberry beds, as if the nets become disarranged the bolder birds will be quick to discover the gaps.—S. L. B.

Liquid Manure and Its Uses.

AS an aid to growth and the production of good crops, liquid manure is invaluable. It is easily and quickly absorbed by the roots of plants and can be reduced to a constituency suitable to flowers, fruits and vegetables. To maintain a supply throughout the season, a stout cask or barrel, such as is used in the distribution of paraffin, is requisite and it should be bedded to about half its depth in a corner of the garden that is in close proximity to the water supply. The choice of ingredients depends to some extent on the material that is available, but I find it a convenient arrangement to solicit the aid of the local butcher, who provides, annually, a mixture of cow and pig manure in a strong, porous sack, to which is added a small pailful of old soot. The bag should only be half filled and after it is tied securely, immerse it in the cask of water and allow it to soak for a few days before use. When applying the liquid manure the strength must be varied according to the nature of the plants, thus the proportion in the case of roses and dahlias is one half liquid and one half water, while sweet peas require a weaker solution of two parts water to one of manure, which should reduce it to the colour of weak tea. The water in the barrel has, of course, to be renewed from time to time and tends to reduce the strength, so that the proportions may be changed as the season advances. Apply once a week when the soil is damp.—S. M.

THE IRIS SOCIETY'S SHOW

THE first impressions of the first show of the Iris Society were very pleasing. There is an ever-present danger of monotony in a "one-flower" show, but the tall spikes of June-flowering irises, with their varied colours, lend themselves to an effective display. The chief trade growers made gardens of irises on the floor in the middle of the hall, and while, of necessity, some sorts were repeated, there was a pleasant variation in their methods of arrangement.

We have termed them gardens of irises, but this is not strictly accurate, Although at first sight the many displays gave the impression of gardens, one soon saw that, in reality, they were collections of cut irises very tastefully arranged. We rather expected that one of the firms which specialise in irises—Barrs, Bunyards, Perry, Wallace and the Orpington Company—would have made an iris garden on the lines of those we have admired so often at Chelsea, and we have no doubt that this was fully considered. But we imagine that it was reluctantly decided that a one-day show did not warrant the expense and great work that would be entailed in such an exhibit.

But it must not be inferred from these remarks that we did not appreciate the worth and artistic value of the exhibits as set out, for they were really admirable, and all concerned are to be congratulated on having such an effective show. While, as may be expected, the tall bearded irises predominated, these were shown in a great variety of distinct and beautiful colours, and with the tall, graceful sibirica varieties, the dwarfer but very fascinating Californian irises and various species, there is sufficient variety to make a satisfying garden entirely of irises.

Judging from the novelties now shown, there seems to be a tendency among the enthusiasts to "go in" for size. The bold flowers set on long stems certainly do take the eye, but it is to be hoped that the raisers will not be entirely obsessed by size, and neglect the chaste beauty and charm of markings of the smaller types. To the ordinary garden lover—to whom the descriptions "June-flowering" and "tall bearded" irises bring forth mental visions of the ordinary German iris seen in most gardens in various shades of blue, it was the newer so called pink varieties that most appealed. While these are not really pink, the general description serves, and there are now many beautiful flowers with standards of beautiful pinkish puce shades of colouring, often flushed with bronze. These and those with yellow standards are exceedingly effective in the garden as well as arranged in vases.

Generally, the competitive classes were well filled, and it must have been gratifying to the executive to find that the amateur members supported the Show with such splendid flowers. Mr. B. R. Long of Richmond Surrey, was the most successful of the amateurs, for, besides several first prizes, he won the Veitch Memorial Medal, offered for the best exhibit shown by an amateur, which was awarded to his admirable group of bearded irises. This included Colonel Candelot, a lovely flower with puce coloured standards and velvety mahogany red falls; Isoline, purplish old rose falls and lilac standards; Ambassadeur, reddish violet standards and velvety maroon falls; Mlle. Schwartz, a very tall flower of pale mauve colouring; Mlle. Denis and Mme. Chobaut, which has white standards shot with puce and yellow, and creamy falls: these are the names of a few of his splendid varieties. In this class Sir William Lawrence, Burford, Dorking, was second; he had various seedlings, and Imperator, Caprice and Opera, with pinkish standards; and Dalila, Iris King and Eldorado in which the standards have yellow colouring.

In the class for a medium sized group of bearded irises, Mr. G. L. Pilkington, Woolton, won chief honours and, in addition to the first prize, received the silver medal of the American Iris Society. His chief varieties were Amber, Dusky Maid, Quaker Lady, Fro and Moonlight. Mr. C. W. Christie-Miller, Sonning, was first in the class for a smaller collection with splendid vases of Souvenir de Mme. Gaudichau, a tall purple bicolor variety; Alcazar, another tall variety, of deep purple colour on the falls, with bronze veining in the throat and bluish violet standards; while Trojana has metallic blue standards and violet purple falls.

The eighteen spikes of bearded irises shown by Mr. B. R. Long were fully equal in quality to those in his large collection. He included Flamenschwert, golden yellow and crimson maroon; Imperator, violet shaded with buff and red; J. B. Dumas, violet rose and creamy yellow; and Edward Michel, one of the best pink irises. Sir William Lawrence was again second.

A great many competed in the class for twelve spikes of bearded irises, and here again Mr. Long was the most successful, and Mr. Pilkington was second. Mr. Long also was first with six similar spikes. Sir William Lawrence was first in the class for three irises other than bearded, and he showed Tenax, Forrestii and Bulleyana. Mr. James Peech, Cautley Park, was second with Luna, Hoogeana and Terpsichore.

The classes for new seedlings were disappointing, in that so many flowers were unnamed; and the same remark applied to most of the many "Selected for Trial at Wisley." The best of the named varieties were Cupavo, a very large flower with long purple falls and satiny mauve standard; Britoness, large pale yellow with golden beard; and Akbar, velvety purple falls and metallic purple standard. All shown by Mrs. W. R. Dykes. Chryso-for delicata, a beautiful cross between Chrysographes and Fortunei; and Te-bracteata, a cross between Tenax and bracteata, shown by Mr. Amos Perry.

The non-competitive groups, shown by Messrs. Barr and Sons, Messrs. G. Bunyard and Co., Mr. Amos Perry, Messrs. R. W. Wallace and Co., Messrs. Waterer, Sons and Crisp, Messrs. Lowe and Gibson, Mr. G. Reuthe and the Orpington Nurseries, contained a great many beautiful irises, chiefly of the tall bearded section, though the graceful I. sibirica varieties, I. Forrestii and the Californian irises were also represented.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

For Sweet Pea Exhibitors.

Tying up "cordon" grown sweet pea plants occupies fully half the total time devoted to all phases of exhibition culture, and many growers would, perhaps, welcome a method which would enable this work to be accomplished at least three times as quickly. I refer to the use of galvanised split wire rings. These rings are about 1in. in diameter and made of pliable wire and their adjustment is very simple. Open the ring with the fingers into the shape of a capital C, it can then be closed round the haulm and support just above a leaf axil. Do not close the ring tightly, but allow sufficient room for the further expansion of the haulm. Practice will enable this simple operation to be done very rapidly and the fastening is just as effective as a raffia tie. The rings are inexpensive and are stocked by most seedsmen. They can be removed at the end of the season and used year after year.—G. C. M.

How to Make the Fireplace Beautiful in Summer.

Most houses have a fireless grate in one or more of the rooms during the summer. They may be transformed into the most artistic, fragrant and coolest looking spots in the whole house with a little care. In the spring ferns should be planted in wooden baskets and earthenware pans; these make a green luxuriant background. The taller ferns are best actually placed in the grate itself and others in front soon hide the bars once their fronds unfurl. Violas planted in round bowls make a brave show for months. As some of the pot plants come into flower in the greenhouse or cold frame, a few may be borrowed for the enhancing of the miniature conservatory. Last year we had lilies, petunias, gladioli, mignonette, clarkia, heliotrope and begonias making a feast of colour and scent. They were more delicate flowering, the gladioli especially, than when grown in full sunshine. Water carefully and apply soot water to the ferns.—C. E.

The Final Potting of Chrysanthemums.

When putting chrysanthemums in their final pots, bring the new compost above the old ball around the sides, so as to make it saucer shape; this allows for the old ball of soil to receive most of the water instead of the new soil. In two or three weeks level it down over the ball. This prevents the new soil getting sour before the roots get into it.—C. L.

Transplanting Seedlings in Dry Weather.

The following is a method I adopted when compelled to transplant some seedlings whose roots could no longer find accommodation in the seed boxes, at a time when the ground was dry and cracked and the sun was hot. First of all I poured a bucketful of water on the patch of ground selected. It disappeared immediately, but enabled me to work the soil. Then I poured on another bucketful of water and very gently but firmly planted the seedlings. These I covered with finely cut coconut fibre refuse, gently shaken over. Seedlings transplanted without this covering died, the covered ones survived.—I. C.

Treatment of Mossy Saxifrage.

The appearance of borders and clumps of mossy saxifrage is often spoilt (especially near towns) by the withering or brown appearance of the centres. This condition can be prevented by a little attention twice a year—in spring and late autumn. Dress the plants by shaking into the clump from the top (using a handfork to loosen the soil underneath at the same time) a good potting soil with an addition of fine stone chippings. A little patent manure should be included in the spring dressing.—D. E.

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry.*

We have selected the following enquiries with their answers, as being of more general interest, and therefore worthy of publication.

Self-Fertile Cherries.

Can you give me the name of any self-fertile cherry that flowers the same time as the White Heart and May Duke. I have had a great show of bloom, but practically a very few are setting. Also, will you tell me if it is coral spot on the mint cutting enclosed? This is the second bed I have had like this, the first I dug up and then started the second a long way away and with fresh mint roots from another garden. If it is coral spot, is it due to lime insufficiency? —F. D., Maidenhead.

As you probably know, most sweet cherries are quite self-sterile. Archduke—a very old variety—is partly self-fertile and would go well with the varieties you mention. If you have three or more sorts in the garden, however—blooming at much the same time and most cherries do—there will be no need to worry about a self-fertile variety, as one sort will cross-pollinate the other. We would, therefore, recommend that you plant Governor Wood and Bedford Prolific. Neither are self-fertile, but planted with those you have already, should crop well. Of course, it may not be faulty pollination that is the cause of your existing trees being unfruitful. Weather plays a very big part and possibly your cherry blossoms have suffered from wind or frost. The disease on the mint cutting you sent is known as mint rust. All affected plants should be destroyed completely and the remaining plants sprayed with a rose-red solution of potassium permanganate.

Damaged Laburnum Leaves.

I would be glad of the assistance of your valuable paper in ascertaining what is wrong with my laburnum leaves. They were three year old trees when I planted them last September twelve months, and last year they did very well. I have them trained on wire rods (the type used for tennis nets), and wire, along my front fence. They started off very well this spring, but in the course of twenty-four hours the leaves of one of them shrivelled up and the buds were stripped from the flowering shoots. As all the leaves in the first tree are not affected, and the leaves of the other trees are not obviously damaged, frost is not definitely indicated, and to me the first tree has the appearance of having been affected by an insect spray of some sort. Could the stripping of the flowering shoots have been done by starlings or sparrows? There is no trace of buds on the ground. The trained branches are not tied over-tightly on the rods and wires. Some that are not tied at all are affected.—S. C., New Malden.

Though you doubt frost being the cause of the leaves of the laburnum tree turning brown in parts, we can suggest no other cause. There is no evidence of disease or attack of insect pest. Should any more of the new leaves turn brown in the same way, send good specimens in a tin box, and we will try to assist you in elucidating the mystery.

Making a Wild Garden.

I have a piece of ground under trees which was used for storing faggots, wood, etc. I had it cleared and have planted it as a wild spring patch. It gets a little sun before the leaves on trees are fully out. It has been very pretty this spring with patches of primroses, grape hyacinths, one or two small shrubs, some daffodils, and narcissi, hepaticas, etc. I also have three wood anemones and A. appenina, white and pink bluebells, ferns, wild strawberries, a few periwinkles, foxgloves, a Dielytra spectabilis, one or two Campanula macrantha (white), columbines, doronicum, camellia, violets, aconites and snowdrops. I am going to scatter a little seed of Ionopsidium acaule to see if it will do there. I want to find something that will make a groundwork for the bulbs and those wild and semi-wild plants, so as to help keep down weeds and make it look covered, but I cannot think of the right thing. I had thought of fine grass, but have given up that idea. Periwinkles are too coarse and would choke primroses and hepaticas (the ground is not very good). If you could help me I should be much obliged and if you could give me several suggestions I might have large patches of several things, perhaps. It seems to need something creeping or self-seeding, but very low and fine.—W. B., King's Langley, Herts.

We suggest the following plants as a groundwork for your bulbs: Acænas Novæ-Zelandiæ and microphylla, Thymus Serpyllum, Corula squalida, Omphalodes verna and Polygonum vaccinifolium.

Primula obconica and its Poisonous Properties.

I shall be glad if you can give me any information about the poisonous properties of Primula obconica? What substance is it which is present in the plant which causes acute irritation, and even a rash to appear on the skin of some people? I have heard that it is not necessary for people who are affected by these plants actually to touch them, but it is sufficient if they are near the plants. Is there any truth in this; and, also, is there any way of preventing such irritation, or cure for the same?—L. C., Esher.

The poison in P. obconica is secreted in the glandular hairs with which it is covered. Although we have known many individuals who have suffered from contact with this plant, we have never known anyone suffer without actual contact, though it is true a few have shown signs of distress at the sight of it. It is just possible that a few supersensitive individuals may suffer without actually touching the plant. There is no known way of preventing the rash except leaving the plant severely alone. If the plant is not handled the rash quickly disappears and no further trouble is experienced.

Transplanting Rhubarb.

I have lately taken over a garden and I find there are some rhubarb roots growing close to the stems of a hawthorn fence. I desire to move them into a more suitable position. Will you kindly inform me how to proceed, in preparation of new quarters and time to transplant the rhubarb roots?—H. M., Poulton-le-Fylde.

Rhubarb thrives best in a rich rooting medium. Trench and manure the new bed early in the autumn and in November lift the roots carefully and replant them 3ft. apart.

TRADE NOTE.

A GARDEN cannot be considered complete, nor can it be fully appreciated, without suitable garden furniture. Cahirs and tables of cane or wicker are the most serviceable for general use, for they are light and so can be carried from place to place, and above all, if of good design, they are exceeding comfortable. The new resilient cane-weave furniture made by Messrs. Hugh Lane and Co., is not only pleasing to the eye, but very durable, comfortable, made in teq best quality and of the finest workmanship. Suites of garden furniture made by this firm are most attractive and look very effective in the loggia, conservatory, or on the lawn and they can be specially recommended to give lasting service.

LYPTICIDE
THE FIRST INSECTICIDE TO USE
NATURE'S INSECT KILLER
EUCALYPTUS OIL.
No insect, no fungus ever attacks Eucalyptus leaves. But the oil is too strong for spraying, cost prohibitive, and oil and water won't mix. By a newly patented method, LYPTOL LTD. produce
LYPTICIDE
a transparent amber liquid in which the oil is permanently suspended and can be mixed with water to any extent, costing (green fly strength)
only 2d. per gallon.
It kills every insect and fungus it touches with a certainty unknown before, yet is non-poisonous and harmless to the tenderest leaf.
NO SLUG, APHIS NOR CATERPILLAR WILL EVER ATTACK A LEAF SPRAYED WITH LYPTICIDE.
T. G. W. Henslow, Esq., M.A., M.H., F.R.H.S., the well known authority on horticulture, tested Lypticide unknown to us and wrote a long enthusiastic letter; "... you have a great future in your discovery; no garden can afford to be without it."
Use it and see for yourself.
Price: 2/6 per pint; 9/- per ½-gallon; 15/- per gallon.
Obtainable from LYPTOL, HARROW.

GARDEN

THE IDEAL GARDENING PAPER

Vol. XCI — No. 2899 Saturday, June 25th, 1927 Price TWOPENCE

ROCK JASMINE (ANDROSACE SARMENTOSA) CLOTHING A DRY WALL.

THE Androsaces are among the choicest of rock plants for a gritty soil and a sunny situation. They provide a wealth of beautiful flowers during the early spring and summer months, and they are excellent subjects for decorative effect in the rock garden or rockery. They are divided roughly into two sections, one represented by such species as AA. carnea, sarmentosa and lanuginosa, which are easy to grow on grassy banks or on dry stony ledges; the other section includes such kinds as glacialis and helvetica which are more difficult to manage and only succeed in rock fissures. All are worth growing, however for their dense mats of pale pink blossoms.

THE GARDEN

VOL. XCI.—No. 2899. JUNE 25, 1927. PRICE TWOPENCE.

GARDEN COMPETITIONS

Garden Championships.

THE Garden Championships which are being organised by the *Daily Express* in conjunction with the London Gardens Guild are likely to be a greater success than last year, if the number of applications for entry forms is any criterion.

It is not generally known that these Garden Championships are a combined effort of more than sixty local horticultural societies and branches of the Gardens Guild. These societies in many districts organise their own garden competitions, and many prizes are awarded. As a modest estimate it is safe to say that over 1,000 actual prizes will be awarded in these Garden Championships. To take the schedule of one society alone, that of the Bellingham Horticultural Society, nine classes, including special prizes for lawn and gardens tended by disabled ex-service men, are provided for different kinds of gardens. That means that anyone residing in the area covered by the Bellingham Horticultural Society will have a good chance in their own district of winning one of these prizes.

In the final judging only the first prize winning gardens are visited by the judges. The following experts have already been appointed to assist in the semi-final adjudication: Marjory Allen, H. Cowley, G. Butcher, W. H. Johns, W. Stewart and G. C. Taylor, B.Sc., F.L.S. The final judges are The Rt. Hon. Noel Buxton, M.P., ex-Minister of Agriculture; The Rt.Hon. Walter Guinness, M.P., Minister of Agriculture; and the Marquess of Northampton. There is still plenty of time for readers to apply for an entry form, which will gladly be sent by the organisers, London Gardens Guild, 124, Walworth Road, London, S.E.17.

Housing Scheme Gardens.

THE predominance of the amateur in the gardening world to-day is one of the encouraging signs of the times. The progressive movement may be said to have originated in the national organisation of allotments during the war, and it has since been developed by the creation of municipal housing schemes throughout the country, a recruiting agency that is directly responsible for the admission of a multitude of enthusiasts that are now to be found in the ranks of horticulture. Despite the difficulties inherent to soil and situation, material progress has been made, while interest in the cultivation of flowers, fruit and vegetables has been stimulated in large cities by the enterprise of the Press. In this connection the *Glasgow Daily Record* has set a good example by providing a championship trophy and money prizes for the best kept garden connected with the twenty Corporation housing schemes. The members of the local seed and nursery trade have also given their support by providing special prizes and a feature of last year's competition was the praiseworthy results obtained by the occupants of the slum clearance houses. This latter branch deserves particular encouragement, and might, with advantage, be adopted by newspapers other than those already undertaking such work circulating in the more densely populated industrial centres in England and Scotland.

Fruit Competitions for Amateurs.

AS announced in the R.H.S. Book of Arrangements, fruit competitions for amateurs have been arranged to be held in conjunction with the Royal Horticultural Society's Fortnightly Shows on July 19th and August 3rd. The schedules for these fruit competitions are now available and copies can be obtained from the Secretary, R.H.S., Vincent Square, London, S.W.1. All amateur gardeners, whether Fellows of the Society or not, are eligible to compete. There are some twenty classes arranged for on both occasions.

Vegetable Trials.

THE Royal Horticultural Society will, during the coming season, carry out a trial of autumn sown onions and cabbages. Seedsmen and growers are invited to send a packet of each variety of these two vegetables which they desire entered for the trials to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (from whom the necessary entry forms may be obtained), to reach him on or before June 30th, 1927.

The Editor's Table.

FLOWERS of a new strain of pyrethrum have reached us from Mr. Harold Lee, a well known grower. The variety sent is known as Mrs. Harold Lee, and the flowers are large (some 3ins. across), of a bright blue pink in colour, with a central greenish disc. They are carried on long stems which would seem to indicate that the strain is vigorous in constitution. The strain should form a valuable addition to the many varieties of this plant that already grace the herbaceous border in our gardens.

This Week's Work

For Gardens in the South and Midlands.

Sow seed of rock plants, such as campanulas, aubrietias and dianthus.

Stake all herbaceous perennials and hoe between the plants.

Top-dress tomatoes in pots and cucumbers in frames.

Feed with liquid manure roses, sweet peas and chrysanthemums.

Start the summer pruning of apples and pears.

Make a final sowing of garden peas.

Remove seed pods of rhododendrons, lilacs, azaleas, etc.

Apply weed killer to paths.

This Week's Work

For Gardens in Scotland and the North.

Plant out celery and Brussels sprouts.

Layer malmaison carnations.

Sow parsley for winter supplies.

Top-dress tomatoes and feed weekly with liquid manure.

Lift bulbs of Darwin tulips and Spanish iris.

Stimulate sweet peas with sooty water.

Give annuals a final thinning.

Transplant Autumn Giant and Walcheren cauliflower.

Sow stocks for winter flowering.

Propagate aubrietias by cuttings taken from non-flowering shoots.

Thin beetroots and French beans.

Complete the planting of beds and borders.

Digitized by Google

FOLIAGE PLANTS FOR BEDDING

Where seed was not sown in March or April, young plants may be purchased now and planted direct in the open beds, which will gain greatly in beauty and effect.

PLANTS with richly coloured foliage, are at all times welcome in the garden providing that too lavish a use is not made of them. As "dot" plants for large beds they are ideal: edgings of the smaller growing sorts are also most effective, but beds composed entirely of foliage have not that charm and brilliancy that one usually associates with the summer garden.

The number of foliage plants available is surprisingly large, but it is an unfortunate fact that the majority—indeed, it might be said all—are only of half-hardy constitution Perhaps the simplest sorts to manage are the annual species, for these are easily raised from seed sown in the greenhouse during spring. However, the perennial sorts should also be grown, for these include among their numbers some of the showiest of all foliage plants.

Taking annual forms first. Kochia trichophylla is at once one of the most ornamental and least troublesome of them all. Seed is sown during March or April in the greenhouse or frame, or even outdoors at the end of the month. It is very compact and rounded in growth, and the feathery foliage, bright green throughout the summer, assumes warm shades of coppery red with the approach of autumn. It is an admirable dot plant for growing with pelargoniums, and is also effective in the autumn among China asters.

"Beet" may not seem a very promising subject for the flower garden, but in Dell's Crimson we have a richly coloured foliage plant which is especially pleasing with flowers of a scarlet or white hue. The dracæna-leaved beet is a dwarf sort, and so is particularly useful as an edging plant. April is a good month for sowing, and the seedlings should preferably be grown along in pots.

A close relative to the familiar Amaranthus caudatus (which is also of some value for bedding purposes), A. melancholicus ruber has large leaves of the most sumptuous shade of ruby crimson. One often sees it used effectively with Cineraria maritima, but it is also of value for growing with light-tinted flowers. Height seldom exceeds 1ft., so it may be used for edging beds of taller growing plants.

THE SILVERY LEAVED LEUCOPHYTA BROWNII IN A BED OF BEGONIAS.

Centaurea candidissima is one of the most familiar of all foliage plants, and right well does it deserve such high popularity. The elegant foliage is of a soft silvery tone, owing to the dense covering of down, and will blend well with flowers or foliage of almost any hue but white. Where the greenhouse is crowded during winter, it is best to buy seedlings from advertisers at planting out time, for this species needs to be sown in autumn if strong seedlings are to be obtained.

Perilla nankinensis will always please, for the foliage is of a fine shade of deep bronze purple. It is very susceptible to damage by frost, and should not be planted out until the beginning of June.

Pyrethrum aureum is worthy of a passing mention, though it is sadly out of fashion nowadays. Still, it is a cheerful little plant with its bright yellow foliage, while it may be had in several varieties, differing chiefly in habit of growth.

Zea is the maize of ordinary folk, and is really delightful, with large drooping leaves that are elegantly variegated. There are several different sorts, with line foliage in rose, green, cream or white. Seed may be sown quite late in April, for the maize is a quick-growing plant, even in its earliest stages.

The number of perennials of a suitable nature is almost legion: they possess the disadvantage that cuttings have to be carried through the winter, and for this reason—in small gardens, at any rate—are never likely to be so popular as the annual sorts.

Alternantheras have leaves most gorgeously tinted—deep purple; yellow; green, purple and yellow; red, etc., being some of the commonest colours. They were highly popular in the old days of carpet bedding, but are now in great demand as edging plants. Cuttings may be rooted in spring in the propagating case. A fairly large number must be propagated, for close planting should be practised with this class.

Acacia lophantha, a relative of the mimosa or Australian wattle, is attractive at all stages of development. The dainty fern-like foliage is particularly pleasing in first year seedlings, and these are most suitable for small beds. They may be lifted in autumn, and grown on if larger plants are required for the following year. Cuttings also root readily in spring or autumn.

Cineraria maritima, very much resembling a very fine silver centaurea, is usually raised from seed each spring, but where extra large plants are required, older plants are, of course, desirable.

Coleus Verschaffeltii, alarming as it may sound, is one of the finest of all foliage plants. The rich crimson foliage is peculiarly effective, with vivid scarlet or other strikingly coloured flowers, while, of course, it is also good with pale hued blossoms or foliage. Small plants are obtained from cuttings inserted in the spring, and these are useful for edging purposes. Larger plants are those grown on through the second year, rich soil being necessary if they are to reach full proportions.

Eucalyptus Globulus, the blue gum tree, produces a sub-tropical effect in the flower

CENTAUREA CANDIDISSIMA MAKES A MOST EFFECTIVE EDGING PLANT.

Digitized by Google

FOLIAGE PLANTS OF ALL KINDS MAKE A DECORATIVE DISPLAY IN SUMMER BEDS.

garden, and, in its younger stages, lends great charm to the beds. It is a rapid grower, however, and old plants soon reach ungainly proportions, necessitating the raising of fresh stock at least every second year.

Echeverias are going out of fashion, but the prim rosettes may still be in favour with some, particularly those who require a plant that will withstand droughty conditions over a long period. Stock is readily increased from offsets, and these will soon reach a size fit for bedding-out purposes. In dry soils, the scapes of orange yellow flowers are often produced fairly freely, and these are quite attractive features during a good year. Lobelia cardinalis is a specially valuable foliage plant, for, in addition to the rich mahogany red leaves, it bears spikes of blossom in the most intense shade of scarlet during late summer. It is particularly valuable for a semi-shady, rather moist bed, for under these conditions it will thrive amazingly well.

Leucophyta Brownii is a rather extraordinary plant, for its dense twiggy habit of growth, combined with the silvery white colour of its leaves, produces an effect that is, to say the least of it, very uncommon. It is not often seen in small gardens, but is very effective wherever grown, and especially so in association with begonias, also with scarlet salvias or pelargoniums.

Melianthus major, with deeply cut and glaucous grey foliage, shall close the list. It is a strikingly handsome plant for a fairly large bed, the younger specimens giving the best returns for any time and labour spent upon their culture. Cuttings should be inserted in autumn, when it will be found that they root rapidly. An alternative method of propagation is from seed, and this method will give good shapely young plants for a small flower bed.

There are many more plants that could be added to the above list, for what are we to say of the cannas and abutilons, the ornamental thistles and the india-rubber plant, of iresine and grevillea—to mention but a few that come to mind? It is hoped that these short notes will stimulate an interest in the subject, but it is impossible to cover the whole field in anything but a book. B. D. S.

PLANTS FOR THE SEASIDE GARDEN

WHEN an ardent amateur gardener, accustomed to a sheltered suburban garden, moves to the seaside, the first few gales are a sad trial; and he is apt to declare in his wrath that it is impossible to grow anything but a flagstaff and a water-butt. Later on he discovers that many things that would not grow near London will flourish in the free, sunny air of the gardens round him, and that there are ways and means of providing the necessary shelter; so he takes courage and sets about making turf walls or getting hurdles.

Of the many kinds of shelter fence none is more suitable for the seaside than the turf wall. This should be well packed, about a foot thick and not less than 2ft. 6ins. high. The top can be planted with thrift or yellow stonecrop, but these will need watering until they are well established. On the inner face of the wall a yellow winter-flowering jasmine may be pegged down, and will soon cover a wide space, rooting at every peg.

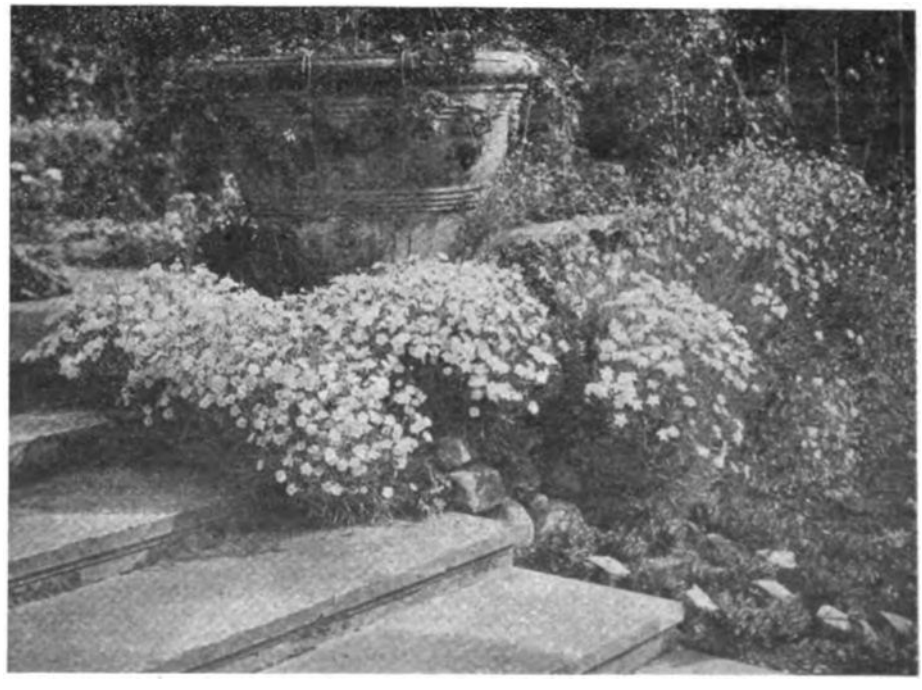
Failing this turf wall, sheep hurdles are a good substitute, and if topped with a little rustic woodwork to carry them up to about 4ft., they look quite comely. It is well to bank up the earth at the back of the borders to form a ridge about 18ins. high, as this additional protection is very valuable, especially until the plants are acclimatised.

Roses will usually do well if procured from a nursery in a rather exposed position. Dwarfs should be chosen, not standards. They should be firmly planted in the shelter of walls or hurdles, well staked and pruned rather hard, not earlier than the end of March. The following varieties appear to do particularly well near the sea: Pharasaer, Frau Karl Druschki, General McArthur, Lieutenant Chaure, Ophelia, Mme. Ravary, Mme. Hoste, Christine, Mrs. H. Stevens, Mrs. Oakley Fisher (single) and Hugh Dickson.

As regards other suitable plants, these may roughly be divided into three classes—tall-growing, medium and rock plants. To which, perhaps, may be added shrubs.

Of the tall-growing sorts, the best are: Anchusa, galega (lavender, white or mauve), helenium, valerian, hollyhocks, evening primrose and lupins. It is a strange fact that these last named, which, in a sheltered garden, are the first to suffer in a gale, will become acclimatised to a windy spot and grow so wiry that they will suffer little damage in any ordinary wind, if given the usual help of a firm stake. The same may be noted of sweet peas, but these must not be coddled in their early stages if they are needed for a windy garden. Sow in a deeply dug and richly manured trench in March, thin out when 2ins. high, put in your pea-boughs firmly and you will find that the sweet peas will be strong and sturdy. That lovely orange variety, Barbara, is especially obliging in this respect.

Medium-tall plants: Perennials.—Canterbury bells, carnations, pinks, Allwoodii,



ROCK PINKS FLOURISH AND PRODUCE ABUNDANCE OF BLOOM IN A SEASIDE GARDEN.

Digitized by Google

wallflowers, stocks, sunbeam poppies, the sturdier of the early-flowering chrysanthemums and flag irises. Of the many exquisite shades of flag irises now procurable, perhaps the two most lovely are Queen of May (the nearest approach to real pink), and Mme. Chereau (cream colour, of great substance and with a wide picotee edge of lavender-blue). (Annuals).—Mignonette, sweet sultan, all kinds of poppies, nigella, red linum and Virginian stock.

Practically all the hardy rock plants do well. Dianthus deltoides, Veronica repens, all the helianthemums (or sun roses), violas, polyanthuses and all the saxifrages. I have left shrubs till the last; but there are many kinds that might well claim to come first, as, for instance, the veronicas, those buxom, sea-loving ladies with robes of every shade from white to deep purple, blue or crimson. It is, alas! true that some of the newer and more gorgeous colours are not quite proof against frost; but for the south coast that is not a matter of great moment. The sea buckthorn and cotoneaster supply a fine show of berries through the winter, while the Ribes sanguinea, the sallow (or pussy-willow), the sea-purslane, the tamarisk and, for the south coast, the escallonias, surely make a goodly company.

Perhaps the time when the high, drying winds are most trying to the gardener is when he is planting out seedlings or putting in cuttings. It is a good plan, when transplanting, to cover the young plants with inverted flower pots for a day or two, until they have had time to take hold. Cuttings may be put in a retired corner and covered with the excellent domestic glass jam jars, the two-pound size makes an excellent cloche, and if well rammed down will stand almost any gale. M. L.

SIMPLE ROCK PLANTS FROM SEED

Raising rock plants from seed is by far the easiest and cheapest way of increasing one's stock. With many of the simple kinds with which this article deals, no difficulty will be experienced in growing on the plants raised from seed sown now. Full cultural details are given below together with a selection of some of the best kinds for the amateur's purpose.

IN a recent issue of THE GARDEN there appeared an interesting article, "Alpine Plants from Seed." In that article, the rarer species were dealt with; but surely it is even more important that the possibility of raising commoner sorts from seed should not be overlooked? Common though they may be, yet, when all is said and done, the gorgeous aubrietias and alyssums, dianthus and campanulas, and other popular plants, form the backbone of the average amateur's rockery. The reason for their popularity is not far to seek, for they are everybody's plants, easy to grow, free-flowering, of rapid growth, and needing little care beyond the original sowing or planting. Besides their undoubted value in the rock garden proper, they should be extensively planted on old stone walls, rough banks, in the crevices of stone steps, and all the other places that a little reflection will suggest as suitable. As it is thus clear that these "common" plants are needed in large quantities, it must be equally obvious that seed sowing is the quickest and cheapest way of getting together an adequate stock for all purposes, and, as many of the varieties mentioned here are true species, they may for the most part be relied upon to come true to name from seed. Seed sowing is, of course, purely a matter of common sense, and there need be no difficulties in raising stock of any plant that is known to germinate fairly rapidly and evenly. As regards the actual sowing, it should be remembered that the thickness of the covering for *all* seeds should be twice their own diameter of finely sifted soil. To facilitate thin sowing, the smallest seeds should be mixed with silver sand, but the larger seeded kinds can be spaced without this aid. Probably the safest place to sow is in boxes or pans of prepared compost, these being placed in a frame facing north and covered with glass until germination has taken place. It will, however, be necessary to turn the glass at least once per day, owing to the moisture which tends to condense on the cold surface. So far as watering is concerned, it is wise to try to avoid this as far as possible until the seedlings are through—beyond the initial watering, of course; but when necessary the finest rose should be used, or, better still, the pans or boxes may be partially immersed in rain-water, thus allowing the water to percolate from the bottom upwards. Where no frame facilities exist, the seed boxes should be stood under a north wall, but never where they can receive the drip from overhanging trees. It is also possible to raise the seedlings in the open ground: in this case the soil should be raked to a very fine tilth, and extra care taken to keep away slugs, which are especially fond of the tender seedlings of some rock plants, and notably so in the case of some of the campanulas—usually the choicer sorts.

THE ROSE PURPLE ERINUS ALPINUS SHOULD BE SOWN IN ITS FLOWERING POSITION.

Where the seedlings are raised in boxes, it is worth while to make up a special compost, though at the same time it may be noted that good garden soil will also serve the purpose so long as ample drainage is provided. A compost that will suit the majority of alpine plants is: 2 parts "ballast"—broken pots, stone chippings, etc.—1 part turfy loam or sweet garden soil, and 1 part finely sifted leaf-mould. Many alpine plants are lovers of lime or chalk, and for these the ballast material may consist of old mortar rubble or, practically as good, broken limestone chips. When the seedlings are ready for transplanting, it must be decided whether they are to go into the open ground or whether they shall continue in the frames. Where space is available, the latter plan is best, for then one is able to have better control of the plants as regards watering, etc. It must be clearly realised, however, that the plants need no coddling, the lights being left off night and day, except that they may be protected from torrential downpours, which might wash the seedlings from their moorings. If the nursery beds are made up in the open ground, my previous remarks *re* slugs should be kept in mind. Soot is an old-fashioned but safe remedy, while recently we have heard much about the value of alum for keeping slugs in check. In any case, traps such as bran, orange peel and so on should be set, and any vermin found in these destroyed without compunction.

The seedlings are moved from the nursery beds to their flowering quarters in autumn, but this is an operation that needs no description. The work is best carried out during dull showery weather, and the plants should be lifted with as little root disturbance as possible, which means, of course, that they should be lifted with as large a ball of soil as practicable.

It is impossible to give more than a brief summary of plants that may be grown from seed, for space is running short. In the following list, lime-lovers are indicated thus (L), and these should have limestone or mortar rubble included in their compost.

Alyssum (L).—A. saxatile compactum is one of the brightest of spring flowers, with dense sheets of golden yellow flowers; the hoary grey foliage is attractive at all times, and the habit of the plant will be improved if it is lightly "shingled" over with the garden shears immediately after flowering. A. spinosum

Digitized by Google

s a sub-shrubby member of the same family, of dense spiny growth, and bearing clusters of white or pale rose blossoms.

Aubrietias come as easily as the proverbia "mustard and cress," but the named sorts are not to be relied upon from seed. The best plan is to buy a mixed packed from a reliable firm; of course, the majority of seedlings will be of a purple or mauve colour, but a few pinks and crimsons should turn up, and these are the colours one prizes most.

Campanulas for the rock garden are numerous, and most of them appreciate lime. They are especially valuable, as they flourish in shade, where it is often difficult to grow flowering plants. The following is a selection from an almost inexhaustible list of species and hybrids: Garganica, blue with white centre, trailing; muralis, purple, 6ins.; pusilla, pale blue, and the white form, p. alba; carpatica, light violet, 1ft.; and turbinata with open cup-like violet flowers, 6ins.

Dianthus is another extensive family and members of this group should also be given lime. For fragrance, there is no more valuable species than fragrans, with single white blossoms. D. cæsius is our native Cheddar pink with fragrant rose flowers in June and July; and deltoides, with rosy purple blossoms, is another native species. There are many others, including alpinus (one of the best) caucasicus, superbus, etc., and the majority are not hard to raise from seed.

Erinus alpinus is a diminutive plant with reddish purple flowers, and is, perhaps, best sown in its flowering quarters, *i.e.*, any odd crevice where the seed has enough soil for germination. Two good varieties are albus, pure white; and carmineus, bright red.

Iberis is the botanical name of an old friend, candytuft, and the perennial forms are of great value in early summer, although they should be used rather sparingly, for their masses of pure white blossom tend to deaden all colours but scarlet, or deep tones such as purple and crimson. I. gibraltarica, sempervirens and correæfolia are three of the most compact perennial species, varying in height from 6ins. to 12ins.

Linum perenne (L) is, strictly speaking, a border plant, but it is of such light and graceful character as to look quite at home in the rock garden, while its flowers are particularly useful for bringing in that all too rare colour—blue. L. perenne grows about 2ft. tall, and rather more robust is L. narbonense, with large deep blue blossoms. L. alpinum is a trailing species with grey-blue flowers; arboreus and flavum have yellow flowers; and in LL. monogynum and perenne album we have two neat white-flowered species.

It is difficult to know what to say of the primulas. If one is lucky enough to get fresh-gathered seed, most of the species will come up freely enough; but with old seed it is usually a slow job. Species for the novice include Beesiana, Bulleyana, Cockburniana, cortusoides, denticulata, hirsuta, japonica and pulverulenta (especially p. Bartley Strain): all of which will be found described in a good seed catalogue.

Saponaria ocymoides is an extremely showy perennial soapwort, with masses of rosy purple flowers; alba is a white form; and o. splendens bears flowers of a lively shade of pink.

Last of all may be mentioned the exquisite rockery violas, chief of which are bosnaica, cornuta and gracilis, with their numerous varieties in mauve, purple, white, yellow and blue. These are all extremely easy to grow, and will often flower the first year if sown early enough. They require a rather moist soil during the time of germination.

When these rock plants are to be grown in dryr etaining walls or on rockery banks it is often more satisfactory to sow them direct into their flowering quarters. Aubrietias, ericas and saponaria are best treated in this way.

B. D.

ALYSSUM SAXATILE, ONE OF THE BRIGHTEST OF SPRING FLOWERS, IS EASILY RAISED FROM SEED.

THE DAINTY VIOLA CORNUTA WILL FLOWER DURING THE FIRST YEAR.

HEUCHERAS FOR THE BORDER.

THE heuchera or alum root is rapidly gaining favour, both as a subject for the herbaceous border and as a cut flower; while it is not to be despised for suitable spots on the rock garden. During May and June, well grown clumps are a feast of colour. The plants are dwarf, but the graceful spikes of bloom are from 1ft. to 2ft. in height. They are extremely floriferous when in a healthy condition, but often the clumps are left undisturbed for a number of years, and consequently they become starved and incapable of producing a good display of bloom. That they are among the most elegant of hardy plants is beyond doubt, and for this reason an effort should be made to grow them successfully. Frequent propagation is recommended—say, every second or third year—and this is best carried out in July, immediately after flowering. The old plants need not be lifted, but a number of the growths should be removed, a few of the old leaves cut away, and then the growths should be set a few inches apart in a cold frame or hand light. A sandy soil is preferable and a little shade until rooted will be advisable. When well established, fully expose the plants, and with the first showery period transfer them to their flowering quarters. The old clumps will be greatly improved by a liberal top-dressing of decayed manure and leaf-mould, or hop-manure.

The forms of H. sanguinea are good, particularly splendens, which is brilliant scarlet. The free-flowering Shirley produces sprays of coral scarlet flowers; while another form, Pluie de Feu, is brilliant red with dark green leaves. In H. brizoides gracillima we have a light and graceful plant. Edge Hall is a pretty rose shade; Walkeri, intense crimson; Beauty, salmon rose; Crimson Spray and Kilnfield White are also worthy of note.

THE BUSY MAN'S PAGE

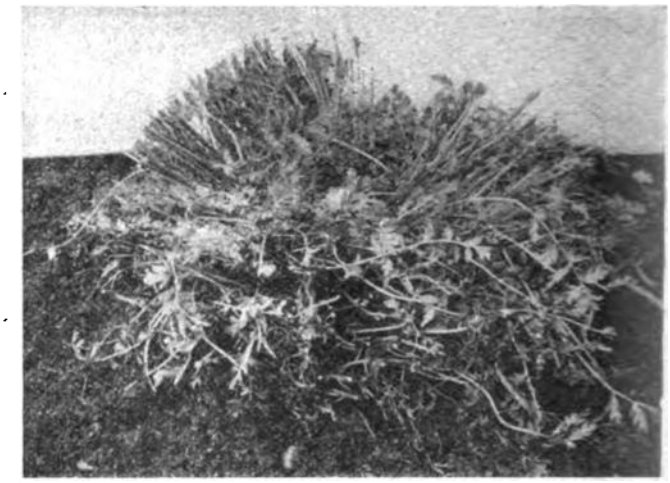
Stimulants for Summer Use.

A MULCH of well rotted manure round plants is a most effective method of feeding them, occasional rains washing the rich contents down to the roots. Many gardeners, however, prefer to dissolve the fertilising matter by stirring the manure into water, the weak tea solution being afterwards applied as liquid manure. Manure, however, is so scarce that the majority of readers cannot get any for this, so they must depend entirely on artificials. Two plans again hold: a light application of manure is sprinkled round plants and bushes, and this is hoed into the surface soil; or an ounce or two is dissolved in a gallon of water and the liquid applied. For general purposes gardeners ought to prefer a balanced, all-round general fertiliser. There are many on the market, like Clay's Fertilizer, Thomson's, Kirk's, Carmona, and probably your own seedsman has a good rose manure or some other. Guano is also good, and then every reader must understand the stimulating nature of sulphate of ammonia, nitrate of soda, saltpetre, phosphate of potash, nitrate of ammonia and other expensive "growth" fertilisers. Use 1 oz. per square yard or ½ to 1 oz. per gallon. Never apply an artificial manure over plants; sprinkle it round them so that it may soak into the ground and reach the roots.

Cutting Back Pyrethrums.

SOME of the earliest varieties of pyrethrums that come into flower in the early days of June are already giving evidence that their beauty is on the wane, and this should be a sufficient indication to the grower that the time has arrived when the plants should be cut back. Those who know these plants well and who make the most of them, cut down the flower-stems to within a few inches of the soil directly the flowers fade. If the fading flower-stems are allowed to remain on the plants for any length of time, the energies of the plants will become speedily exhausted, and the chances are that only one crop of blossoms will be obtained. The prompt removal of the fading blossoms, and the flower-stems too, should ensure the development of a second display of their welcome blossoms in July and August. For the purpose of illustration, in Fig. 1 a plant of a single-flowered pyrethrum, with the flowers just beginning to fade, is shown. The stiffness of the petals has gone, and in some cases they are actually drooping. In the case of double-flowered sorts, the blossoms begin to wither and shrivel. It is at this period that the flower-stems should be cut back to within a few inches of the soil.

1.—A CLUMP OF PYRETHRUMS ON WHICH THE FLOWERS ARE FADING.
The stems are now ready for cutting down.



2.—THE SAME PLANT CUT DOWN TO WITHIN A FEW INCHES OF THE GROUND.

Fig. 2 serves to illustrate the drastic way in which the flowering plants should be cut back. A plant of this description has great possibilities. If the soil round about the plants that are cut back is lightly forked over or loosened, and then well watered, subsequently applying a mulching of well rotted manure from an old hot-bed, the plants will quickly respond with new and vigorous flower-stems, well repaying the grower for the extra trouble taken. The plant illustrated has been mulched in the manner indicated. When in good health the plants enjoy a fortnightly application of manure-water, and copious supplies of clear water in dry weather.

The Use of Ashes and Cinders.

ASHES and cinders are useful in more ways than one in the garden, although the residue of a coal fire has practically no fertilising value. In the case of heavy ground these can be spread on the surface and dug into the soil. The cinders will play a useful part in opening up the clay so that air can pass freely into it and, as well, the drainage of water is facilitated. Fine, gritty house ashes spread round young plants will keep off slugs and prevent them from doing damage. The very fine dusty matter may be mixed with soot and used to dust the plants for killing insect pests. When planting bushes, mix a few large clinkers with a little lime and put a layer of these in the bottom of the trench. This will help the soil drainage and also check any pests that might burrow up among the roots of the plants.

Radishes in Summer.

TO maintain a succession of radishes, sowings should be made at intervals of about a fortnight right until the end of September. During the summer it is most important that the sowings should be on cool shady borders where the soil is comparatively rich. Beds of loam and leaf-mould that may have been used for transplanting bedding and other subjects would be admirable for radishes. Unless radishes can be grown quickly, so that they are tender and crisp, they are of very little value. It is far better to sow the seed in drills, as this allows frequent surface-stirring of the soil and also leaves space between the rows for a mulch of short manure which will prove very helpful during the summer. Before sowing the seeds, soak the drills with water, and, after sowing, cover in with fine soil. A certain amount of thinning will be needed, and, of course, one selects the poorest plants. When young, every part of the radish plant may be used in the salad bowl, and the later thinnings may be washed and added to a mixed salad. In very scorching weather it is a good plan to cover the seed bed with mats or some form of shading until the plants come up. Abundance of water must be given if there is no rain, and this should always be applied in the evening.

Spring Bedding Plants.

INITIAL preparations count for so much in gardening that we hasten to remind everyone that suitable preparations must be made for next spring's bedding needs. Not only must seed be sown, but cuttings can also be rooted and, in odd instances, old stools divided up; actual needs and present stock determine the work which is required. Wallflowers, no doubt, have already been sown, but it is not yet too late to make a further sowing, provided that it is done at once; plants from earlier sowings may be pricked out in vacant potato or pea borders or in any spot where they may grow. Aubrietias are best sown in the frame, the seed being so small; keep the frame close and shade until the seeds germinate, and in due course transplant into a shady nook in the open. Myosotis or forget-me-nots are also favourites and enter into many a delightful colour scheme; the catalogue reveals many choice named sorts; but, as a low bedder, M. nana alpestris is very fine. White arabis can also be raised from seed, but, if a stock is available, a very good plan is to take cuttings of the ends of shoots, and dibble them in, in a semi-shaded border, keeping them moist for a time. Primroses and the earlier polyanthuses require dividing up or seed may yet be sown; transplant into an open border plants raised from earlier sowings. The double daisies can readily be raised from seed or old plants may be torn into single crowns and planted. Violas, too, are very fine; and cuttings of Snowflake, Maggie Mott and other bedders may be rooted readily in the open at the present time.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

How and When to Cut Flowers so as to Preserve their Freshness.

RARE floral gems have their special attraction for the gardener, but flowers of the "cut and come again" variety will always be sure of popularity, chiefly because they can be used for indoor decoration, or can be cut and given away to friends, without in any way robbing the garden. Sweet peas, coreopsis, geums, roses, snapdragons and others are among the plants which give us more and more blooms, if they are constantly picked before they develop seeds. But these flowers, to give the greatest amount of satisfaction, must be cut with care and understanding.

It is generally accepted that the best time to cut flowers is in the early morning, before the dew has gone from them. If this cannot be done, the next best time to cut is in the late evening. Flowers cut at this time should be immediately put into water, and allowed to remain there until the morning before being arranged in vases, or before being sent by post. The petals of flowers should not be allowed to stand in water, but if the flowers are of the type which soon droop their heads, they may be immersed up to the neck in water, a tall vessel being used for the purpose.

All flowers begin to fade when the process of fertilisation has taken place. It follows, therefore, that if flowers are plucked before they are open, and brought indoors, where insects are less likely to find them and where fertilisation is delayed in consequence, they will last better than those plucked when fully open, whose pistils have already received the pollen from other blooms. Poppies are remarkable in this respect. A full blown poppy will last, perhaps, only an hour, but a poppy cut in the early morning, just as the green sepals are bursting from the flower head, will last for three or four days in the vases. Poppies that have been carried a distance should have the ends of their stalks cut under water when they are being arranged.

Roses are best cut in the bud, not only because their beauty is generally best before they are full blown, but because they frequently lose their colour more in the sunshine than indoors. To cut them with short stalks is a mistake. Long stalks are a great asset in arranging decorations, and, in addition, roses of the hybrid tea types that are pruned back after flowering, will usually yield a second crop of bloom. One good bud low down on the flower stalk, *i.e.*, just above its union with the main stem, is sufficient to leave for the second crop of flowers.

Occasionally flowers, such as clarkias, tend to droop their tips when cut for indoor decorations. The trouble can in some cases be avoided by the simple method of pulling the plants up by the roots instead of cutting the stems. Clarkias pulled in this way will last well in the flower vases, and the same process could be adopted with other annuals.

Of flowers that are specially suitable for cutting, which could be grown in special masses, or rows in the vegetable plot, some of the prime favourites are coreopsis, stocks, love-in-a-mist, gypsophila, sweet peas, dwarf sunflowers and sweet scabious (annuals), and among the perennials, linaria, coreopsis, single dahlias, chrysanthemums, gladioli, gerbera, carnations and pinks.

ORANGE-SCARLET GERBERA (TRANSVAAL DAISY) MAKES A CHARMING SUBJECT FOR INDOOR DECORATION.

A Shower of Stars.

FEW plants give such prolific displays of tiny star blossoms as do the saxifrages. The one illustrated above is Saxifraga hypnoides, and is one of the most accommodating of plants. Its simple needs are moisture and a little sunshine, and it will grow in places where the soil is poor and scanty provided it is not allowed to become too dry during the hot weather.

A balcony tub or box would be easily transformed into an object of great beauty by planting this saxifrage. The flowers are just now at their best, but the green foliage is perennially beautiful, and a mass of this plant could therefore be grown in the centre of a tub or shallow pan and surrounded by seedlings of a later flowering plant, such as lychnis or nasturtiums.

New Ideas for the Garden.

WHAT an enormous amount of interest and beauty in a garden is due to the extra furnishings, apart from the flowers, which we are able to introduce. Of course, money counts in these features, and some of the ornaments and summer-houses, such as were on view at the Chelsea Show, can cost fabulous sums. But there are a number which are well within the reach of most amateur gardeners, and which would add considerably to the artistic effect of their gardens.

S. HYPNOIDES, A QUICK-GROWING MOSSY SAXIFRAGE SUITABLE FOR EDGING OR CARPETING.

Seats are, of course, the first in importance in any garden. For of what use is a garden if one may not sit in it and enjoy its fragrance and restfulness? It is hardly necessary to stress the need for the seat to be in a shaded and, if possible, secluded part of the garden. In a small garden the seat should be unobtrusive. If it is painted a glaring colour, it will seem to monopolise the whole garden space. For the really tiny garden a dark-stained wooden seat is, perhaps, the most suitable. Teak furniture, such as is supplied by Castle's Shipbreaking Company, Limited, is ideal. I have had a seat of this kind in constant use for over ten years, and it is still in splendid condition, so that, though the initial expense is fairly heavy, the furniture is cheap in the end. Common deal furniture, made by the home carpenter and stained with creosote, is a fair substitute.

Orange canvas is growing in favour for garden awnings and hammocks. It is a pleasant change from green. Those, such as Messrs. Gamage offer, are in themselves a brilliant and colourful addition to a lawn, and their colours can be repeated in the extra deck chairs and cushions that are stored for garden use.

All kinds of chairs, tables and settees suitable for garden use are now made from fine cane. These have the special advantage, in addition to their beauty, of extreme lightness, making it a much less laborious task to move the furniture from place to place in the garden, or to bring it into shelter during bad weather. This furniture is very comfortable, and can easily be cleaned by washing when it becomes soiled. Messrs. Hugh Lane and Co., Limited, specialise in this class of goods.

There is no question about the value of furniture in the garden. Gardens supplied with ornaments which are merely ornamental and not useful lack friendliness. Indeed, it is extremely doubtful if such mere "ornaments" are ever really beautiful or add to the artistic appearance of the garden.

NOTES ON THE FLOWER GARDEN

A Little Lily Pool.

NOTWITHSTANDING the assurances of catalogues, people with small gardens and moderate incomes regard the growing of water lilies as out of reach. They have seen the large ponds in some public garden covered with the gorgeous nymphæa flowers and revelled in their beauty; and they have never realised that they may have that beauty in their own little back garden at the cost of a few shillings!

The materials necessary for making a small lily pond are some good-sized pieces of sandstone or limestone (old bricks will do as a substitute), some Portland cement, barrow-load of good fibrous loam and, lastly, a handful of water snails to keep the water clear. The nymphæas may be had at any price from eighteenpence to several pounds. A single plant of Marliacea rosea, costing 3s. 6d., will soon increase until it covers the surface of the water with its exquisite coral pink blooms. Gladstoniana, price 5s., has huge snow white flowers.

Choose the sunniest place you can spare, and dig it out to the depth of about 3ft. in either formal or irregular shape. The size, of course, depends upon the space available, but a pool 5ft. or 6ft. across will give room for several varieties of lilies. A good shape is a rough figure 8, divided across the centre by some piled-up blocks of stone, thrown in after the cementing of the pool is finished.

The floor and, perhaps, the first layer of stone forming the sides should be covered with cement; above that it is more picturesque, because more natural, to cement the joints only. This must be very carefully done, so that no leaks may be left. The topmost layer of stones should be varied in size and shape, placed irregularly and projecting over the edge. When the pool is finished, allow the cement to dry hard before putting in water, and then wait for a day or two before planting, to make sure that it is watertight.

Put in about 6ins. of soil and 18ins. of water; this is enough for nearly all the hardy lilies. Plant the lilies in old potato baskets, placing turf on the surface of the soil to prevent its being washed away. Sink them gently where you want them to flower. They will soon form extra plants and, as the baskets rot away, will establish themselves in the bed of the pool.

There will be plenty of room for two or three water plants other than lilies. Aponogeton distachyon (water hawthorn), the fresh-water arum (a miniature replica of its greenhouse cousin), Villarsia nymphæoides (which only needs to be thrown into the water) and the ordinary arrowhead are all excellent.

The beauty of the pool will be increased by damp-loving plants in a soil chiefly leaf-mould and sand, round the edge. Hanging curtains of aubrietia (Dr. Mules or Pritchard's A.1.) and the mossy saxifrages may be trained over the bordering stones.

A pond like this may be a beautiful joy stocked only with our English wild plants, the yellow and white water lilies of our rivers, the water iris, arrowhead and bogbean, forget-me-nots and kingcups.

EVEN THE SMALLEST GARDEN CAN HOUSE AN ATTRACTIVE LILY POOL.
Here is one in a small garden made bright by a wealth of moisture-loving plants around its banks.

You can make your pool now, putting in water lilies of budding size, as well as young plants of any of the aquatics or moisture-loving plants which have been mentioned. All these will soon establish themselves.—G. H.

One of the Best of Rock Garden Shrubs.

THIS year Lithospermum prostratum has proved itself one of the finest subjects on the rock garden. To bring it to this state of perfection, no great labour or expense is required; just bear in mind that this plant has a great aversion to lime, and remember that two year old plants from cuttings invariably produce the best and largest quantity of bloom. It is quite hardy, and should be given a trial on all rock gardens. Being of a trailing or prostrate habit, it should be planted so that the growths will fall over a rock or down a sloping bank. I prefer the latter, for then it is possible to do a little top-dressing after flowering, and the growths are pegged down at the same time. The flowers are a beautiful gentian blue, and are freely produced in May; but there is hardly a month when a few flowers are not in evidence. The variety Heavenly Blue is lighter in colour, the blossoms being a luminous sky blue; while the plant is more compact in habit than the type.

In some gardens this plant is quite a success without any special effort being made, and in such instances the soil will be a light sandy loam, and probably deficient in lime. As a rule, a rooting medium similar to that used for heaths will be suitable, and in such a compost it will form patches a yard square which are eventually covered with brilliant blue flowers.

Propagation is effected by cuttings taken during July and August, and they will form roots in sandy soil if afforded the protection of a cold frame or hand light for two or three weeks. Young unflowered shoots with a heel attached make the best cuttings.

L. purpureo cæruleum.—This is a rare native plant, quite distinct from the above in growth, but the flowers are somewhat similar, being a rich blue when fully expanded. The leafy stems will attain a height of 2ft. or more, at the apex of which are produced the clusters of blooms. It is perennial, and should be cut down to the ground level every winter; then young shoots are formed which will flower freely in May. Of rather rampant growth, it must not be planted in the best parts of the rock garden, but around isolated rocks or in close proximity to the wild garden it will prove most effective. Like L. prostratum, this plant has flowered freely this year, and, moreover, the colour of the blooms has not been surpassed even by the gentians.—T. W. B.

Rock Roses Under Trees.

ALTHOUGH the rock roses are naturally lovers of the open, there are several which do remarkably well in the partial shade of fairly open woodland, always provided the soil is light and congenial. Under tall oaks, for example, I have grown for many years groups of that attractive white variety often sent out under the name of Cistus obtusifolius, the prettily waved leaves of which are a deep glossy green. This rock rose blooms abundantly where it only gets a minimum of direct sun, and the blossoms are of good size and creamy white with a faint yellow stain at the base of the petals. Where the soil is extremely dry and impoverished, as it often is in woodland, C. salvæfolius will usually do remarkably well. Even under tall pines, where few shrubs will prosper, the sage-leaved cistus will give a good account of itself, and the closely allied C. corbariensis might be tried in similar conditions. All the above can be planted at any time from pots, and in regard to the preparation of the soil I never do anything beyond giving the ground a little loosening. All cistuses like lime or chalk, but these are by no means essential.—A. T. J.

Brooms from Seed.

Sow This Month.

IT does not seem to be generally realised that many of our most beautiful brooms are very easily raised from seed, a method which not only commends itself on the score of economy where many plants for grouping are required, but home-raised seedlings usually transplant more satisfactorily than those which have been packed. The old white broom (Cytisus albus) is one that may be produced in this way, and among the taller ones I question whether there is a lovelier species or variety in cultivation. C. scoparius will, of course, come as readily, but it does

Digitized by Google

not seem to be common knowledge that its valuable late-flowering (July–August) form will also turn out very fairly true from seed. C. Andreanus, the very striking yellow and maroon Normandy variety, if not absolutely reliable from such a source, will always give a good percentage in the right colour, plus some very pretty variations always useful for groupings. The Montpelier broom (C. monspessulanus), a first-rate species for growing where the very similar Genista fragrans proves too tender, can be grown with the greatest ease from seed, and this is equally true of the beautiful G. virgata, one of the loveliest of the race. C. nigricans, so invaluable as a late summer bloomer, is not less amenable to increase by this means, and then there is that splendid old shrub, the Spanish broom (Spartium junceum), whose seed readily germinates.

There are several other highly ornamental species which might be included in this list, but enough has been said to draw the beginner's attention to this important phase of broom culture. I usually sow the whole of the above in June, making an ordinary seed-bed of free, light soil in an open part of the garden. The seed is placed very thinly in drills about ½in. deep, covered and firmed down with the back of a spade. An occasional sprinkling in dry weather may be desirable, and precautions should be taken against slugs. This and keeping them free from weeds are all that is necessary until the plants are 6–12ins. in height, when they may be moved to their permanent positions. Many will be ready to transplant in the spring following the year of sowing.—J.

Sweet Woodruff.

A Charming Native for the Wild Garden.

IN these days, when so much attention is being given to wild and woodland gardening, one cannot overlook the charm of this delightful native. Throughout the spring and early summer its prettily whorled leaves are sheeted with snow white stars and the spent foliage is often dried and bunched for the sake of the fresh fragrance of new-mown hay which it retains for many months. Though it is apt to spread rather too freely among choicer plants, the woodruff (Asperula odorata) is admirable for the rougher parts of the rock garden, where it will serve the same purpose as tiarella and other subjects for draping the rocks or covering the ground beneath shrubs. But I think it is never such a joy as when associated with ferns in partly shaded woodland retreats.—J.

PRIMULA JAPONICA AND SOME OF ITS VARIETIES GROWING ON THE BANKS OF A STREAM.

An Easily Grown Primula.

IN Primula japonica and its varieties we have an easily grown plant, and one that should be planted on a large scale wherever its culture is possible. It is not too particular regarding soil, so long as there is sufficient moisture at the root during the growing season, and if partial shade can be provided the various shades of colour are more effective. In some gardens will be found a damp border with a north aspect, and here P. japonica would be quite at home; other damp and shaded corners could also be located, while the margins of streams and damp spaces in the woodland would be ideal stations for this stately primrose. Here the plants will thrive and reproduce themselves freely from seeds; in fact, so numerous are they occasionally, that a certain amount of thinning becomes a necessity. The flowers vary considerably in colour, but the type, a deep and rich crimson, is still one of the best. Different shades of pink and red are available, while a few of the pure white forms mixed with other colours renders the batch most pleasing. The illustration depicts a large number of P. japonica in variety growing by the side of a stream in the interesting gardens of Colonel MacNabb at Chepstow. Here the display was very wonderful at the end of May.

These primulas are readily raised from seeds if sown soon after they are ripe either on a shady border outside or in pans. If pricked off in good soil they soon attain flowering size. Good varieties can be divided immediately after flowering, but as a general rule seedlings give the best results.—T. W. BRISCOE.

FOR THE WOODLAND GARDEN FEW PLANTS ARE AS EFFECTIVE AS ASPERULA ODORATA.

A Yellow Daisy for the Border or Rock Garden.

A LITTLE yellow-flowered composite which is suitable for the front of a border or a position on a rock garden is Chrysogonum virginianum. This plant is a hardy herbaceous perennial, and it is remarkable for the length of time over which it will produce its bright golden yellow flowers, which are borne in sprays and are very attractive. As a rule, chrysogonum grows to the height of from 5ins. to 6ins. but the larger growth is only seen when the soil is deep and moderately moist. When the plant is happy it will often remain in flower from April to October, and it is worth while at the time of planting providing the leaf-mould to which chrysogonum is partial. The species is useful on account of the fact that it does not demand the sunniest positions and, on the whole, does better in somewhat shaded situations. Chrysogonum is readily increased by means of root division, which is best carried out in the spring, although in this respect the plant is very accommodating.—L. B.

SOME SWEET PEA DISEASES

A look-out should be kept for the appearance of disease on your sweet pea plants, and immediate measures taken to remedy the trouble. Suggested measures are given in this article.

SWEET PEAS are always liable to be attacked by certain diseases and some of these may have very serious results indeed. It is important that the amateur grower should be on the look out for early signs of the trouble in order that prompt steps may be taken. The following is a list of some of the more important sweet pea diseases, with their causes and suggestions for remedial and preventive treatment.

The Mosaic Disease.

This trouble is evident by the yellow mottling of the leaves and, in certain varieties, there is a thickening and curling of the tissue. The plants tend to become stunted and growth is almost suspended for a time. In the case of a strong-growing sort the trouble may be overcome altogether, so that finally the plant, although late in flowering, may not be much the worse for the experience. The origin of the disease is not fully understood, although it is probably caused by the attacks of some minute organisms like bacteria. Green flies, owing to the way in which they puncture the leaf tissue, seem to give rise to the disease if they have recently been on infected plants. The mosaic disease is often confused with streak (to be described later), although really the yellow spotting of the leaves is very distinct in appearance. Plants infected with streak hardly ever recover, but prompt remedial measures usually yield good results in the case of mosaic disease. The best step is to syringe the plants with a solution of iron sulphate (½oz.) added to 1 gallon of soot water. The soot water is made by placing about a peck of soot in a bag into a tub containing 30 gallons of water and allowing this to stand for a week. The iron sulphate and soot solution should be applied once a week on both sides of the row of plants between two and three quarts being allowed for each yard treated.

Streak.

Just at the time when the sweet peas are beginning to flower the first signs of streak are to be noticed. Evidence of the trouble is to be seen in reddish-brown spots and streaks along the stem, which seem to have their origin near the ground. Heavy dews appear to favour the progress of the disease, which, at such times, spreads with great rapidity until the tissues of the main stem are destroyed and the plant comes to a miserable end. Certain bodies found in the spots have been identified as bacteria—the particular species having been given the name of Bacillus lathyri. Streak is also prevalent in the common clover and it often appears where sweet peas have never been grown before. Probably the land has been previously infected by clover or some other legume. It is also possible that at times streak may be introduced into a garden with manure. It must be pointed out that streak is not a root infection, the attack being made through the stomata of the leaves. The only measures which can be taken in the case of streak are preventive. Mulching along the rows of plants with strawy manure is good, for this prevents soil, which may be infected, splashing on the plants in rainy weather. Another step which may be taken is to syringe the plants with a solution of permanganate of potash, 1oz. of the crystals being dissolved in 6 gallons of water. The mixture should be applied at intervals of ten days until the plants are well advanced towards flowering, care being taken to coat the under sides of the leaves as well as other parts. Another measure, which undoubtedly prevents streak, is to carry out some partial sterilisation of the soil. The soil for seedlings should be sterilised by steaming it at a temperature of 180 degrees; then the soil where the plants are to be sown should be soaked with a solution formed of 1 gallon of carbolic acid or Lysol to 200 gallons of water. Another way is to use a 1 per cent. solution of commercial formalin (formaldehyde, 40 per cent.), which is used on the ground at the rate of a gallon to each square yard. Cover with sacking for four days to keep in the fumes. Then uncover for a fortnight, after which the sweet peas may be sown or planted.

Mould.

This trouble is caused by a parasitic fungus and is recognised by yellowing of the leaves and blotches on the stems; eventually these become brown and are finally spread over with a delicate white outgrowth, which is the mycelium of the fungus. Mould affects the seed vessels and the seeds and the germs of the disease may start an attack almost as soon as the young plants are up. Seeds which are suspected may be soaked in water at a temperature of 135 degrees Fahr., and allowed to remain until cooling takes place. Another way is a short immersion in a solution of permanganate of potash, allowing 1oz. to 8 quarts of water. The spread of mould to healthy plants may be checked by dusting the foliage with powdered quicklime and sulphur, using twice as much lime as sulphur. This should be repeated at intervals of three or four days. Badly infected plants should be pulled up and burned without delay.

Root Rot.

This trouble is due to the attacks of a fungus. Affected plants have very little in the way of roots as the fungus destroys these as soon as they appear. On occasion the fungus works up the main stem to the height of 2ins. or 3ins. above the ground, but it never travels far upwards. Attacked plants show a yellowing of the foliage and usually the whole specimen will collapse from below. Sweet peas affected by root rot quite often do not die soon and they will sometimes linger on during the whole of the growing season, in such a miserably stunted state that they are worthless as regards flower production. The fungus makes its attack through the soil. It seems usually to be introduced in manure and it is most common on land that is rich in organic matter. To prevent root rot, soil sterilisation on the lines indicated should be carried out.

Wilting.

This trouble most commonly arises in young plants. The seedlings seem to be quite healthy and then suddenly they fall over and collapse. On occasion wilting may appear in older plants, but it nearly always occurs before flowering time comes. Immediate dressings of lime will tend to check the spread of the disease.

Collar Rot.

Here the first signs are a drooping of the tips of the shoots and the younger leaves, which is followed by the complete collapse of the plant. The fungus which causes the trouble lives in the ground and attacks the plant just where the stems join with the soil. Usually the cause of collar rot is introduced into gardens with animal manures, especially if these are strawy. All affected plants should be removed and burned without delay and the ground treated with quicklime. As a preventive measure the collars of the plants may be dusted with air-slaked lime. On badly infected land scatter straw or other dry litter on the surface and then set this on fire. After this it will be possible to grow sweet peas without fear of collar rot.

Anthracnose.

The chief signs of this trouble are whitish spots on the leaves which become brittle and drop off. The shoots and flowers may also be affected. Usually the disease puts in an appearance about midsummer, when the plants are in bloom and at their best. It is suggested that it may be prevented by spraying the plants with half strength Bordeaux mixture in mid-June and a fortnight later. When the disease has appeared infected plants must be burned and afterwards the ground should be deeply trenched. S. L. B.

GERANIUMS WITH PRETTY FOLIAGE

THE passing of the custom of beautifying a garden for the summer months with plants of a half hardy character, which, in these days, is referred to as "the bedding-out mania," was largely the result of a lessened interest being taken in pelargoniums (better known as geraniums) with pretty foliage, which was their chief attraction. To-day, it is rare to see a collection of any size, and, in a way, it seems a pity that such plants should have been allowed to go out of favour. I remember them in my youth as being regarded as very important in summer bedding arrangements, but at the best they had but a short time out of doors—from about the middle of June in many quarters until early in September, when they were brought back under the cover of the greenhouse roof and warmth. It was not often that the plants were turned out of pots, as such a procedure was considered too risky for getting up the plants in early autumn. I remember in my own home how many of the tricolours were never trusted out of doors at all, but were kept in pots not far removed from the greenhouse roof; and were not allowed to bloom, so that the colour of foliage might be intensified. The foliage was the only thing to be considered. As far as I remember, Mrs. Pollock, with gold and carmine and brown intermingled, appeared to be the one sort from which some of the later varieties sprung. Bronze bicolors were represented by Black Douglas and Maréchal MacMahon. Silver tricolours by such sorts as Dolly Varden and Prince Silverwings. White-edged sorts seem to have been retained in many places, as not infrequently, where summer bedding is practised, one notices Flower of Spring and Bijou. It is some time since I saw in any quantity a variety, the centre of the leaf being green and the edge crimped with yellow, bearing the name of Golden Chain; and Cloth of Gold and Crystal Palace Gem, once to the fore as bedding plants in beds on lawns, appear to be dying out.

Fashions in horticulture—as in many other things — change, and the favourite of one generation is seldom met with in the next, and this is the position of these geraniums possessed of beautiful foliage. Will the pendulum swing again in their favour? Many plants to-day that furnish beautiful flowers are popularised through societies which have been formed —sweet peas, dahlias, roses, for instance. If it were possible to get together a really representative collection of these admittedly pretty coloured-leaved geraniums and exhibit them at one of the principal shows, would there not be many who own greenhouses, and who have never had an opportunity of seeing these plants, be imbued with a desire to grow them? I think so — but there is this against it, their growth is very slow and two, or even three, years in the life of some of them makes little appreciable difference in their size—still, putting this on one side, it is to be regretted that their culture is not more taken up. W. F.

THE FRUIT AND KITCHEN GARDEN

Summer Pruning and Training of Fruit Trees.

PRUNING fruit trees in summer may take the form of successive shortening of laterals, removal of excess shoots and disbudding, *e.g.*, peaches. The objects of summer pruning are to aid the formation and ripening of fruiting wood, to control the development of the tree and to help the fruit to mature.

Apples and Pears.—There are two methods of summer pruning practised with the apple and pear. One is the cutting back of the laterals to five good leaves and the tipping of leaders at the end of July or in August preparatory to spurring back to two or three good buds in winter, and the other that of restrictive pruning. The latter is more complicated and requires adaptation according to the variety and locality in which it is grown. Essentially it consists in pinching back laterals which have attained the size of a pencil in June, July and August, to two or three good leaves, excluding the basal rosette, with the subsequent pinching of sub-laterals to one leaf. Those shoots which are smaller than a pencil should not be pinched, but merely bent over to check the flow of sap. This will aid the development of the basal buds and help to keep the spurs close to the main branches. Leaders should just be tipped. A point to be borne in mind with regard to training the specialised forms of trees, such as the cordon, the espalier, etc., is that regular and equal development of the sides and the upper portions of the tree may be obtained by an equalisation of the leaf area over both sides and the upper and lower portions of the tree by the removal of some of the excess shoots from the strong growing area and the cutting of others back one half, leaving those on the weaker side unpruned.

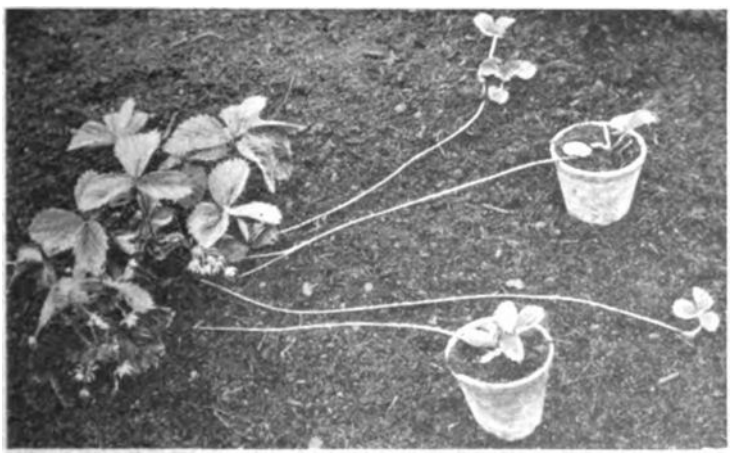
Peaches and Nectarines.—The summer treatment of the peach and nectarine is more one of disbudding, thinning and stopping than one of pruning proper. The fruits are borne on the wood of the previous year, consequently a fresh supply of shoots is required each year. All that is required for summer treatment is the rubbing out of the lateral leaf buds on the fruiting lateral with the exception of the terminal bud and one or two at the base of the shoot. Finally, only one basal shoot is left, the present fruiting shoot being removed to this basal shoot when the fruit has been gathered. This basal shoot should be trained into position as soon as possible. Any excess laterals may be removed if they are not required for extension purposes, or shortened back if a balancing of growth is required.

Plums.—The plum fruits on last year's wood and on spurs, so that it is not possible to treat all growths in the same manner as for the apple and pear. Shoots which are required for extension purposes should be trained in place. Shoots from spurs may be pinched back to five good leaves after they have attained the length of 9ins. to 10ins., stopping sub-laterals at one lead. Weaker growths may be left unpruned.

Cherries.—With cherries trained on walls the balancing of growth is of great importance, the tendency with sweet cherries, which fruit principally on spurs, being to grow more from the spurs at the top of the tree than at the base. Consequently, pruning must take the form of equalisation of leaf area by thinning. As a rule, little summer pruning is required, but if shoots tend to become overcrowded they may be thinned, and shoots of 1ft. cut back to 3ins. to 4ins. Morello cherries fruit on last year's wood and require little treatment beyond thinning.

Garden Peas.

I HAVE come to the conclusion that most varieties crop quite satisfactorily when well grown, and so I confine my remarks to some of the points connected with the words "well grown." The roots of the pea penetrate to a great depth; indeed, they must penetrate deeply if the peas are to carry a heavy crop, hence deep cultivation is a preliminary which must never be scamped. Manure should always be liberally used, natural or artificial, and to do its good work properly it requires to be thoroughly mixed with the soil to the depth dug. The manure used should contain little, never excessive, nitrogen, for the peas make their own nitrates and need little from the grower; phosphates and potash always tell, however. The trench system is probably best in all gardens, but more particularly where the soil is not all it might be naturally. Always let the soil preparation be carried out well in advance of sowing, but fork it over once or twice to aerate, sweeten and ameliorate it before the seedlings send their roots into it. Always scoop out a trench the width of the spade and sow evenly in this. Cover with at least 2ins. of soil and see that this covering is firm. Scatter soot on top—and fate will do the rest.—C.

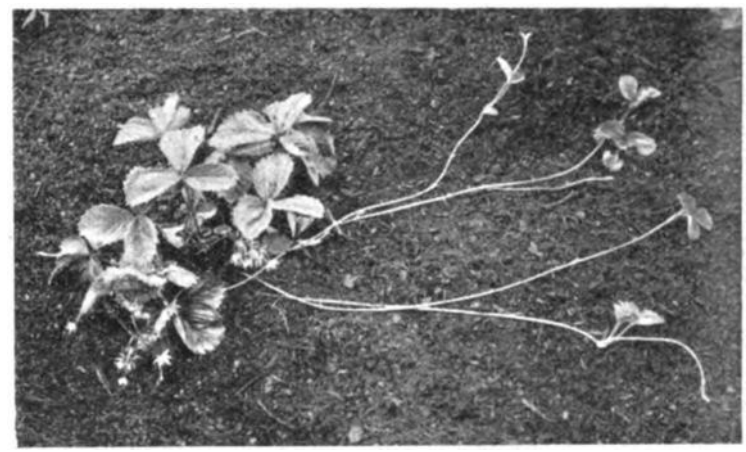


STRAWBERRY RUNNERS LAYERED IN 3IN. POTS

The pots are best plunged in the ground round the old plant.

How to Layer Strawberries.

STRAWBERRIES are increased by means of runners. These runners should be selected from the healthiest plants and pegged down as soon as the fruit is gathered. It is best to take no more than two or three runners from any one plant, the strongest should be selected, the remainder cut off.



A ROBUST STRAWBERRY PLANT WITH FOUR VIGOROUS RUNNERS.

In this case the runners are pegged to the ground.

Runners may be pegged down in small squares of turf, in 3in. pots in a compost of loam plus very decayed manure, or pegged to the ground. The runners will require a little water especially if in pots, but carefully avoid over-watering. Pots should be plunged in the ground round the old strawberry plant. Runners should be severed from the parent plant as soon as they are well rooted. This should occur somewhere about the end of July. As a change of stock is desirable every third or fourth year it will be necessary to take sufficient quantity of runners to replace them. Runners from maiden (one year old) plants are best.—B.

Summer Treatment of Raspberries and Loganberries.

THE summer treatment of raspberries and loganberries may be summarised under the following headings: (1) Cultivation, (2) Manuring, (3) Treatment of Young Canes, (4) Pests and Disease Control.

Cultivation.—The ground between the rows should be kept clean by hoeing and forking very lightly over and to prevent the loss of moisture. A thorough hoeing is as as good a watering, so, for the best results, keep a fine tilth.

Manuring.—During the summer months the plants should be given a watering with dilute liquid manure. This will greatly assist the fruit and the development of the plant. In addition a top-dressing of horse manure, well decayed, placed round the roots of the plants will keep them cool and be of great benefit. Never allow the plants to suffer from lack of moisture. Give a thorough watering when necessary.

Treatment of Young Canes.—Since the young raspberry canes will be the bearers of fruit the following year, their care is of utmost importance. Thinning of canes should continue. Select about six of the strongest canes and tie them in, remove all others, thus directing the energy of the plant into the canes chosen. The number of canes selected will vary according to the variety and the age of the plant. As soon as the old canes have fruited remove them and burn them. This will give the young canes every

Digitized by Google

opportunity to become thoroughly ripened by admitting light and air.

CONTROL OF PESTS AND DISEASES.

Raspberry and Loganberry Beetle.—The larvæ of these beetle are hatched in the flower buds. They feed on the fruits and then hibernate in cracks in the bark. Remove the fruiting canes after fruiting and burn.

Raspberry Moth.—The larvæ of this moth bores into the base of buds and into the pith of the shoots, killing them. Remedy as above.

Clay Coloured Weevil.—The damage is done by the maggot, which feeds on the roots of the plant and by the weevil attacking the young fruit buds and blossoms.

Control.—Remove weeds and rubbish from plots and treat the soil with a soil fumigant. Shake off weevils on to a tarred board at night.

Tomatoes in the Open.

EXCEPT in the milder nooks of our country, tomatoes in the open are "a bit of a lottery," but it is well worth trying to grow them where space under glass is not available. Of course, a warm, sunny and sheltered corner is required and soil just right for them; probably more errors are made in regard to the soil than in anything else. The border reserved for them must not be richly manured. It should, however, be in good heart and, above all, it requires to be well drained and porous. Dig it over now, dig deeply; give it a liberal sprinkling of lime in any of its inactive forms and, before planting out, rake in a dressing of artificial manure, including potash (or wood ashes). It is also most important to have strong, sturdy, well advanced plants to plant out now. They should be, when planted out, well forward in growth, showing evidence of or actually carrying the first truss of flowers. Thereafter they are kept to a single stem, fed when the fruits begin to get large and not allowed to grow beyond one leaf above the third truss. Expose the fruit to the sun by pulling aside the leaves and aim at ripening three trusses of fruit rather than growing six unripened trusses.—H. H. A.

Mushrooms Outside.

THE essentials of successful mushroom culture consist in following out the natural conditions of growth as far as possible and the selection of a good grade of spawn.

Good horse manure obtained from corn fed horses and from which the long straw has been removed is best. It is necessary to use manure of the same age for the bed. The manure should be turned every other day for a while and then every three days, completing the turning process in about three weeks or at the period when the temperature has reached its maximum and is receding. Water, if dry.

Any situation will do for the mushroom bed, but under a north wall is best for summer purposes. The beds should be about 5ft. by 4ft. at the base and the ground which should be well drained must be covered first of all with 2ins. of good loam, which has been obtained from a pasture and stacked for some time. The manure should then be placed on top to a depth of 4ins., after ramming firm with a brick or shovel and then 1in. loam, with another layer of manure 4ins. and finally a top layer of ½in. of loam. Each layer should be compressed and the dimensions given are those of the compressed layers.

The beds should be made to form a ridge at the top. When the temperature of the bed is at 70 degrees to 80 degrees and is receding, plant the spawn, breaking the spawn brick into pieces the size of an egg, 1in. deep. In about ten days cover with another 1in. of loam. Keep the bed well watered.

In summer mushrooms should be obtained about six weeks from spawning and a bed should last about three months.

OUR PHOTOGRAPHIC COMPETITION

Some of our competitors seem to be under the impression that the photographs which they submit must of necessity be taken in their own gardens. This is by no means essential. As will be seen from time to time, awards are not so confined. There are beautiful and interesting garden pictures to be found all over the country, in public parks, in the gardens of friends, in wayside cottage gardens, as well as in those of more imposing character, and photographs of these are just as acceptable and likely to be instructive and interesting to other garden lovers. For these reasons they are equally as welcome as those taken in the particular garden with which the competitor is associated, though in the latter case opportunity is afforded of intimate notes of personal experience which in themselves may help other readers.

A few years ago this was a muddy pond; a drinking place for the cattle of the adjoining fields. Gradually it has changed its character by the introduction of various plants. Those proving unsuitable or unhappy have been removed. The remaining plants revel in luxurious growth and show to full advantage against the woodland background. Hardy primulas, gentians, greater spearwort, hepaticas and mimulus border the water, lilies and bog bean have become thoroughly established in the pond and the protecting shrubs include escallonia, spiræa, ceanothus and philadelphus in variety. The approach is by a winding pathway edged with pillar roses and lavender, and dwarf conifers stud the sloping lawn to the house.

The guinea photograph, sent in by A. DEACON, *Stockton.*

This shows an attractive way of planting up an entrance path to the house. A bright display has been obtained over a long period by planting forget-me-nots on each side, with blue and mauve irises and deep red tulips. Every year this border is dug over after the plants have finished blooming. W. F. WAGNER, *Harrow.* Award of 5s.

Digitized by Google

This photograph, taken at the beginning of this month, shows a part of our terraced garden, with a dry wall erected just over a year ago. The bank in the foreground is planted with a variety of irises, campanulas, etc., and carpeted with pansies, double arabis and Mrs. Sinkins pinks. The honeysuckle over a trellis screen in the background on the right was planted only three years ago. MRS. P. S. RICHARDS, *Swindon.* Award of 5s.

This is a photograph of my garden and lily pond taken on May 22nd this year. The garden faces south and is situated within four miles of Charing Cross. In size it is 35ft. long and 22½ft. wide and it is of my own design and the result of my own work. The pond is four years old and the dry walls two years. The pond itself is some 7ins. deep and about 1½yds. square and contains water lilies. There are many rock plants on the dry walls surrounding the pond, including aubrietias, alpine phloxes, Arenaria balearcia, thymes, sedums, and catmint. W. S. SANDIFORD, *Upper Tulse Hill, S.W.2.* Award of 5s.

This shows a small portion of a terrace garden built entirely by my husband and myself. The work was only commenced in January of this year and I think it now shows how wonderfully well planted a new piece of rock work, such as this, can look, even in a short time. Once it becomes really established it will gain greatly in appearance. The flowers in the border are aquilegias, geums, aubrietias, tulips, etc., and wallflowers in the main bed. None of these plants was planted until February, and the result is now very gratifying. MRS. E. RICKARD, *Cradley, Malvern.* Award of 5s.

This photograph of a portion of my garden, which is now only in its second summer, illustrates the effect which can be rapidly obtained by the careful grouping of lupins in the mass. They are white, yellow, blue, violet and pink, mostly raised from seed at very little cost. Here and there a tall anchusa is placed to enhance the effect. The foreground round the sundial is what may be called a rock garden in one plane, composed of cushions of white saxifrage (S. Wallacei), pink thrift, blue veronica and pinks. Early in the spring blue primroses cover the ground. This little garden is at the end of the lawn about 18ins. above lawn level. The whole was built up of waste earth and stones. E. CAHEN, *Dunsford.* Award of 5s.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

PROBABLY no other occupant of the garden has suffered so much from the unseasonable weather as roses. Their backward condition is not confined to any particular area or locality, but extends over the greater part of the country. No sooner does the young growth make its appearance than it succumbs to the frost at night-time and subsequent exposure to the sun during the day. These extremes of temperature began in the early days of May and have continued in a more or less degree ever since. To emphasise the absence of summer weather further, ground frosts ranging from one to five degrees were experienced on successive mornings during the second week of June; and the prevalence of a northerly wind threatens a continuance of chilly conditions. This late cold spell had an injurious effect on apples as the fruit which had just set and gave promise of a plentiful crop, was nipped so severely that the thickly clad clusters have disappeared from the branches and provided a brown carpeting on the surface soil underneath. It is all very discouraging.

As some amateurs have a hazy idea regarding the proper time for pruning shrubs, it is opportune to remind them that a number of flowering shrubs should be cut immediately after the period of bloom is over. The extent of the operation varies according to the character and habit of the species, but as a general rule very little pruning is required. This applies particularly to the flowering currant, azalea and berberis, which belong to that class of shrub that only requires any straggling growth to be cut off with the object of improving the form of the bush. Lilac and broom, again, need different treatment. The shoots of the former which have flowered should be thinned out and cut back to within a few inches of the old wood, while the strong growing species of the latter must be pruned annually to keep them within bounds, but they must not be cut back into the old hard wood.

In a recently published work on vegetable gardening the author says that "it is not good management to dig in manure at the time of planting potatoes," and to emphasise the point he adds in italics, "*it is distinctly bad management to line drills with manure and place potatoes directly upon it.*" Singularly enough, I expressed somewhat similar views at a meeting of Mossparк Horticultural Society a few months ago, but the meeting heard a different story from a member of the trade, who stated that the best potatoes he had seen in Dumfriesshire were grown on that very system which was largely and successfully practised in different parts of the country. Theory and practice were at variance, and, as the latter was justified by results, growers will adhere to the old-fashioned methods of culture.

Many readers are familiar with Incarvillea Delavayi, a beautiful hardy perennial with rosy carmine bell-shaped flowers spotted with yellow and brown. It is usually grown in masses or in beds by itself in soil that has been well nourished with peat or leaf-mould; but I was agreeably surprised to find it thriving on a wall in an enthusiastic amateur's garden within the city boundary of Glasgow. Two years ago a specimen of that well known variety was planted in a pocket in the stonework, and from the beginning of June the wall was resplendent with bloom. It would be interesting to learn if any other reader has had experience of I. Delavayi as a wall plant in Scotland, because its behaviour at Glasgow not only testifies to its hardiness, but suggests an increased sphere of usefulness as a garden perennial. Later on, I intend to describe this remarkable garden, which has been created and formed by the owner himself. The pillars and stonework forming an ornamental parapet or balustrade were brought from Hamilton Palace, and, together with a sundial, have been embodied in a scheme that is pleasing and distinct from the orthodox forms of landscape gardening. Moreover, it demonstrates the possibilities of gardening in an industrial city whose atmosphere leaves much to be desired.

Rhododendrons are flowering irregularly this year, and complaints regarding the absence of bloom are quite common on the part of small growers who introduced a few specimens within the past three or four years. It is a usual experience for the plants to produce a profusion of bloom in the first season after planting and fail to flower in successive years. Contributing causes may be traced to the practice of Dutch raisers who export their products when they are liberally clothed with flower buds and to the subsequent non-removal of the seed vessels after the period of bloom is over; but it is more than likely that the disappointing results are due to unsuitable soil conditions. Light loamy ground which is naturally moist and well drained is best suited to the welfare of rhododendrons; but they also thrive in heavy soil, provided lime is not one of the constituents. Leaf-mould is a great help in keeping the root system, usually to be found near the surface, moist and cool, and, being moisture-loving plants, copious supplies of water during dry weather are advantageous if the soil is sweet and suitable. Many of the hybrids are as hardy as gorse, but they do not all flower sufficiently late to escape the late frosts in May, and in our uncertain northerly climate the amateur gardener will obtain more satisfaction by observing the principle of "safety first," which may, in this case, be interpreted as restricting choice to those varieties which can withstand the weather and do not open their flowers before June.

Housewives who are in need of a good room or window plant should try an imantophyllum, an evergreen subject with long, strap-shaped, thick, leathery, glossy leaves which send up spikes of bright orange red tubular flowers every spring. There are several beautiful new hybrids with colour variation which are prohibitive in price, but one of the older and common kinds that cost 3s. has stood in my dining-room window for thirty years. During that long period it has never failed to bloom, and is the very picture of health. Beyond an occasional teaspoonful of Thomson's Plant Culture it has received no special treatment, and, being pot-bound, it requires re-potting in fibrous loam and leaf-mould every second or third year. ST. MUNGO.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Phlox Laphami as a Pot Plant.

This lovely phlox is not only a plant suitable for the rockery or border, but is most charming for the cool conservatory. I have grown it for several years in pots and its lavender coloured flowers in early spring have been much admired. Take cuttings in June. They will make nice bushy plants for flowering the following spring, providing they are pinched well back (twice will be sufficient, so as to encourage plenty of growths from the base). I strike a few each year and grow them the second year in pots. These make good specimens, after that they can be planted out in the rock garden or border. Ample drainage is essential, instead of crocks I prefer mortar rubble and plenty of grit with the potting soil.—F. W. D.

Seed Sowing in Dry Weather.

Not a week passes at this season without some kind of seeds requiring to be sown, and as they are more liable to fail from heat and drought than they were in the spring from the cold, attention should be given to prevent this. In all cases open drills for the seed. Fill them with water at once and again in two or three hours' time, soaking the ground well before sowing; then sow and cover at once with dry soil. It is astonishing how long this dry covering will retain the moisture, and the seed will germinate and the plants grow freely.—J. P.

Potting Materials.

Now is the time to look out for potting soils for the coming season. It may be difficult and too expensive to get the best loam, but good results can be obtained with any close texture sward, the thing is to get plenty of fibre and not cut more than 4ins. thick, 3ins. is better. If plenty of road or lawn parings can be found, this would be useful; it should be stacked sward side downwards with a layer of leaf soil every 6ins. When this has laid for three months and is chopped down it makes splendid potting material. If this and ashes from the smother fire, charcoal, peat, leafsoil, sand, and moss, both hedge and sphagnum, are in readiness, work can be carried out without delay when the time arrives.—G. W.

A Cheap Weed Killer for Paths.

Nothing makes a garden look so untidy as weedy paths, and yet how often one sees them neglected, mainly because it is a tedious job to keep them clean by the laborious method of weeding. A cheap effective weed killer can be made by mixing a pint of creosote with a gallon of water (preferably hot). Sprinkle it over the paths with a water-can and rose, and it will kill all weeds in less than twenty-four hours. Care should be taken not to allow any of the mixture to touch border plants. A path measuring 3ft. by 75ft. can be done in a few minutes at a cost of less than a shilling. Two applications a year will keep paths absolutely free from weeds.—R. B.

Propagation of Alpine Plants.

To strike cuttings of alpines quickly and safely prepare a small frame or bell-glasses with sand and leaf-mould. Keep the cuttings closely covered in *full sun*, water once or twice daily, and in three weeks or less the cuttings will have rooted, and ought to be uncovered and fully exposed. Few failures result from this treatment.—N. S. C.

Leaky Water-cans.

As an alternative to soldering a leaking can the following is a good method: Spread some thick tar over the parts that leak, and on top of this pour some boiling pitch. When this has dried the can will no longer leak, nor will it do so for a long time afterwards.—J. L.

WHAT OUR READERS SAY

PRIMULA MICRODONTA ALPICOLA.

SIR,—A plant under this name was put up for a certificate at the Chelsea Flower Show and won an award. It did not appear to me to be the true P. microdonta alpicola, but a cross, having the leaves of P. microdonta and the flowers of P. Florindæ. I had several similar plants on my stand and also one very distinct from the others, which I consider the true P. microdonta alpicola. I wonder if any authorities on primulas saw the plant which won the certificate and what opinion they formed as to its being the true P. microdonta alpicola or a cross.—JOHN MACWATT, *Duns*.

THE BOTTLE-BRUSH TREE.

SIR,—I am enclosing the photograph of a plant of Callistemon speciosus (Bottle-brush tree) of Australia. I purchased this as a small sprig with one bloom on it three years ago, and this spring it displayed over sixty blooms. I am surprised this handsome plant is not more popular, as it is easily grown in a cold greenhouse. It requires an abundance of water, especially while in bloom.—W. N. STANLEY, *Sydenham*.

THE BOTTLE-BRUSH TREE IS A HANDSOME AND EASILY GROWN PLANT FOR THE COLD GREENHOUSE.

CAMELLIAS OUT OF DOORS.

SIR,—In a recent issue of your paper I saw an interesting note on the growing of camellias out of doors. Your readers may be surprised to learn that in our gardens in County Down, about three miles outside Belfast, we have a bright red camellia, a semi-single with white blotches on the petals and a yellow centre, which blooms beautifully every spring in the open air. This tree was planted out several years ago, having previously been in one of the hot houses, and has been most successful. It is in a sheltered spot and there are two or three other camellias beside it, one of these, a lovely pale pink, has also bloomed this year, but the red one has excelled itself this season, being absolutely covered with flowers, and on May 15th I cut a branch from it with six blooms on one stem!

I thought this would be of interest to you and your readers, and this must testify to the mildness of our Ulster climate!—FLORENCE E. HENDERSON.

TRANSPLANTING POPPIES.

SIR,—I was quite interested in an article you published on transplanting poppies. For three years we have been raising annual and perennial poppies for the trade, in wooden boxes or flats as we call them. When the seedlings are large enough, we transplant them into boxes containing heavy soil and later cut them out and set them into the garden without the slightest wilting or difficulty. Our customers have equal success. Our surprise was great at our first success, because we had always believed such transplanting impossible.—MRS. HERBERT S. HICKS, *Rockford, Illinois, U.S.A.*

SLUG REMEDIES

SIR,—Every gardener must be interested in the letters appearing in THE GARDEN referring to the slug pest. Remedies are of two kinds—the one killing the slugs, and the other protecting the plants. This refers to the main practical effect of the treatment—the substances used are all capable of killing slugs if applied in sufficient quantity and sufficiently intimately to the slug.

We know that slugs die when common salt is sprinkled on them. We also know that a ring of fresh soot will protect a valued plant—so long as the soot remains dry, slugs will not cross it. A soluble neutral salt, such as finely ground kainit, scattered over the ground will kill many of the slugs that happen to be on the surface, and the lethal effect is greatly increased when a soluble poison, such as copper sulphate, is added to the kainit. But to kill, these substances must fall on the slug. Slugs underground, or otherwise protected, escape, and rain rapidly dissolves and dilutes the dressing so that it has no lasting effect.

The writer's own experiments indicate that an alkaline solution of copper sulphate and commercial ammonium "carbonate," or the same mixture (Cheshunt compound), applied dry, may be used in greater concentration without harm to the plants.

It is, however, to a different class of compounds that we look, after experiment, for the greatest measure of slug control. These are solid substances, not substantially soluble in water, but having a high vapour pressure at ordinary temperatures. They are of the class known as soil insecticides, or sterilisers. Naphthalene and p-dichlorbenzene are typical. Such substances can be applied to land and worked into the soil, and when this is done they continue to permeate the soil with a vapour for many weeks, killing slugs and other pests, and in the later stages still making the soil so distasteful to pests that plants are not attacked. Reasonable doses may be forked in among growing plants if necessary, without harm to the plants. A number of commercial preparations of this class are on the market. Experiments with one of these ("Sterole") indicate that the preparation may be sprinkled over the ground at the rate of 4oz. per square yard without harm to plants. Ground treated this way was sown with lettuce seed one week after treatment in a slug-infested garden and there was no loss of seedlings. Experiments are continuing, and if results seem of general interest to gardeners, they will be communicated.—J. BERTRAM WARD, *London*.

EXPERIMENTS WITH PRIMULAS.

SIR,—I am conducting an experiment with primulas which I think may be of interest to a few of your readers. It is that of planting a number of primulas in fairly large blocks, with the idea of getting pure seed from the plants in the centre of the respective blocks, and also of testing their hardiness.

They are planted in a small pinetum, so get considerable shade as well as shelter, and the ground is always moist. In fact, the conditions are such as were recommended recently by THE GARDEN, and also, I think, written about by Captain F. Kingdon Ward.

I had made no preparations beforehand to have plants in a similar state; some were old plants broken up, others seedlings, and all the plots may quite well be mixed. Quite a lot of P. acaulis, polyanthus and varieties have been planted to separate blocks of the Candelabra primulas, but I have not taken any note of those. In all, about 2,700 plants were put in.

I give a table of the Asiatic primula planted under woodland conditions, with numbers from which you will see the losses are comparatively small, being on the average under 3 per cent., and some of the deaths were, I think, due to the plants being trampled on during the winter.

I have come across cases of pelorial growth in two species of the candelabra group—P. Bulleyana (F. K. Ward's variety) and P. Cockburniana. They were grown in rich soil with shade. The lower tier of the flower stem developed leaves as well as flowers, the upper part of the flower stem was broken off, and there were quite big tufts of leaves by autumn, with air roots at the base. Those tufts were potted up; they struck readily making strong growth. They were grown on in a cool frame, but, unfortunately, were planted out before the cold snap in the end of April, when they were badly scorched by the cutting wind and frost.

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry.*

We have selected the following enquiries with their answers, as being of more general interest, and therefore worthy of publication.

Summer Treatment of Grape Vines.

This is the first summer in a new greenhouse. My grape vine was thoroughly pruned, but the foliage now is so dense that the other plants, notably the tomatoes, get hardly any sun. Is it wise to cut away some of the larger leaves or shoots when they are too close?—J. B., Sydenham.

Select one good branch on each spur of the rod and retain it, removing all the others. Stop the branch retained at three joints beyond the show of fruit—the bunch of grapes—and afterwards sub-laterals while small, beyond the first leaf. Retain all main leaves intact.

Treatment of Lilacs After Flowering.

I have a number of lilac trees which have been planted about fifteen to eighteen years. Last year they had little blossom, this year they were excellent. What can I do to ensure a good lot of flowers next spring? To what extent (if at all) should I prune them? Some of them are rather shapeless. Round about and in among the main stems or trunks are a large number of small shoots from an inch or two to a couple of feet. Are these seedlings, or are they from the main root? Should I cut them down, pull them out, or leave them?—G. H., Sanderstead.

Remove the old trusses from your lilac trees when the flowers fade. Cut out all thin and weak twigs crowding the middle of the trees. The growths at the base of the trees should be removed, as they are suckers, not seedlings. Carefully dig or pull them up without damaging the roots of the trees. Shorten the longest branches of the shapeless trees to improve their appearance. Thin the new shoots at the ends of the branches if numerous, removing the weaker.

Cutting Back Helianthemums.

When is the right time to cut back helianthemums? I have some very old plants which are now carrying long, leafless, straggling growth from the roots. If I cut them back to the old wood will they break again?—G. I., Sutton.

Cut back to the hard wood immediately after flowering, or do it now if there are not sufficient flowers to make it worth while waiting for the growths to finish flowering.

Diseased Tulips.

I am sending some tulips for your inspection. The foliage of all the tulips in the garden has turned brown like this. Out of hundreds I have only picked about two bunches. We had very severe frosts here the first week of May, seventeen degrees for several nights running, and the gardener thinks the tulips were all frosted; but, since reading the question in a recent issue about "fire" in tulips and your reply, I wondered if these are infected in the same way. I dug up some of the bulbs and they appear quite healthy. I shall be much interested to hear your opinion. The tulips have never been like this before in this garden. I had 300 new bulbs last year which flowered splendidly.—E. L., Lanark.

The foliage of your tulips is infected with "fire." Some varieties are more subject to infection by this complaint than others, and the fungus spreads with great rapidity under conditions of overcrowding and damp atmosphere. The trouble does not enter the bulbs, but they should be carefully examined when lifted, to see that they are not attacked by any other pest. If they appear healthy they should be well dusted with flowers of sulphur before storing. The spores of the fungus may adhere to the outer skin of the bulbs, and this should be peeled off before the bulbs are replanted.

Pinching Sweet Peas.

My sweet pea plants are now from 12ins. to 20ins. in height, and nearly all of them are showing buds (from the seed growth). Only four plants out of fifty have, so far, developed basal growths or side shoots. As it seems to me very early for buds to appear (they were planted on April 21st, would you advise pinching out the buds now showing? They are very healthy-looking, but it is the first season I have known them grow so tall without any side shoots. Of course, none of them has ever been pinched.—G. S., Reading.

The late severe frosts in many districts did much harm to sweet pea plants. It may be responsible for the trouble with your plants. As it is now getting late in the season for the removal of flower buds—advisable in the case of stunted plants—we advise you to cut the opening flowers regularly, water and feed the plants, and no doubt with this treatment they will be satisfactory.

Replanting an Old Border.

Can you give me any suggestions as to replanting an old and very wild border? The border is about 20ft. or 30ft. by about 3–4ft. It is on a slight slope facing south, and is backed with a yellow Scotch briar all the way along, which looks very pretty now it is out; but the border is higgledy-piggledy—masses of cerastium spreading over it, knapweed, perennial iberis, and single rocket and other miscellaneous things. It seems to me that low-growing plants will look best on it; but I do not want to be at the labour of bedding it out each season. It is on one side of a path, with just a narrow grass edge between it and the path. Also, there is a bit of rockery near the house which is a terrible jumble—chiefly feet square of cerastium, with large ferns at the back. What is the proper way of dealing with these very overgrown rock plants? Should I cut away the greater portion after flowering? I intend taking cuttings. Would it be best to root up the whole thing in the autumn and replant with young rock plants? It is also all mixed up with ground elder.—O. W., Windsor.

Directly such plants as the cersatium have flowered, cut them back severely and insert cuttings of all that you like best in a cool border in some other part of the garden. Next autumn and winter dig up the whole of the border and replant. Treat the rockery in the same way, thoroughly clearing it of roots of weeds. The rockery may be replanted next March. Cerastiums should not be grown in a rockery. Raise some seedlings now of campanulas, delphiniums, lupins, pyrethrums, gaillardias, lychnis, Michaelmas daisies, Coreopsis grandiflora, erigeron and Scabiosa caucasica. In autumn sow seeds of antirrhinums—the dwarf and intermediate varieties—and you will soon have stock for refilling the border economically next year.

Insect Pests of Apple Buds.

I am enclosing some apple blossom buds which some insect attacks. All the apple trees are more or less affected. The buds appear all right until they unfold, and this insect then eats into them and ultimately the buds drop off. Could you give me any advice about this? The trees had grease-bands on and were sprayed in winter.—C. R., Yarm, Yorks.

The damage to the apple blossom buds sent for our inspection has been caused by the small caterpillars of the Tortrix moth. These caterpillars are most destructive, eating out the buds almost before they unfold and doing considerable damage later on to young foliage that does appear. The blossom clusters have also been damaged by the apple blossom weevil. To prevent similar damage another year we suggest that you tie a band of sacking or hay round the apple tree trunks now, to trap the weevils. Remove and burn the bands, with hiding weevils, in autumn. Spray the trees in January with a good tar distillate wash, instead of the ordinary caustic alkali, using Mortegg or Carbokrimp. In spring, spray the trees with arsenate of lead, once just as the bloom clusters begin to unfold, and again when the petals have all fallen. The important spraying is that with lead arsenate in early spring, so that bud-eating catepillars are promptly poisoned.

Treatment of Neglected Land.

I am shortly removing into a new house, built on a rectangular site of old market garden, containing 900 sq. yds. It is six years since it was a market garden and my intention is to design it very similarly to that described on page 338 of THE GARDEN *for May 28th. The land is a mass of nettles and rough grass, and I should like your advice on how I should prepare the land before starting the design. I have been advised to dig it 2ft. deep and bury the nettles, etc., or, alternatively, to burn all top growth and use the ashes for mixing with the soil. Another suggestion was to fill the whole site with potatoes.—A. M., Newcastle-on-Tyne.*

It is now too late to plant potatoes, but the advice was good. If it is convenient, take off all growth, weeds, etc., and burn the rubbish, preferably in small heaps all over the ground; the fires will then kill insect pests and seeds of weeds, the ashes enriching the soil. Do not bury roots of nettles or tap-roots of coarse weeds, as, if you do, you will have more trouble. After the burning of the rubbish, trench the ground and remove every bit of weed root that is found. By far the best policy is to devote time this summer to cleaning the ground thoroughly, thus, than attempt to grow any crops, as the season is well advanced.

Silver-Leaf Disease in Plums.

I am sending shoot from one of my Victoria plum trees which appears to me to be attacked with silver-leaf disease, and I should be obliged if you would let me know if this is so. Last year I cut away a branch similarly attacked, but this year it seems to be spreading to other branches, and I should like to be sure of the cause of the trouble before cutting the tree further. Another branch is gumming badly and appears to be dying. Could you tell me the cause and preventive measures? This tree has always been troubled with suckers.—R. F., Dartford.

The plum shoot sent for our inspection is undoubtedly silvered, and all such should be cut out and burned. The "gumming" that has set in on another branch may be due to many possible causes, but as the tree is generally unhealthy it will probably be best to grub it up and burn it. With a combination of silver-leaf and gumming the tree stands very little chance of recovering, particularly as it is of the very susceptible Victoria variety.

EARLY SUMMER IN THE GARDEN.

IT is at this time when the garden should look at its best with a brilliant display of colour and bloom in the beds and borders. Among our early summer flowers irises and lupins are particular favourites, and no garden border should be without clumps of each. They combine well together and their range of subtle colourings and graceful habit render them most desirable plants for the small garden. This year the display of June irises and lupins has been particularly fine.

THE GARDEN

VOL. XCI.—No. 2900. JULY 2, 1927. PRICE TWOPENCE.

FORTHCOMING FLOWER SHOWS

The National Sweet Pea Society.

THE Annual Show of this special flower society, which is to be held at the Royal Horticultural Hall, Westminster, on July 7th and 8th next, promises to be fully equall to any previous show. Earlier in the year the weather conditions were very unfavourable to sweet peas, but the spell of warmth and the more recent showers have improved matters considerably. The society has arranged several new classes for the amateur members. One, which should be popular, is open only to those who have never won a first prize at one of the Society's shows. There is another for members who grow their own sweet peas unaided, while the Novices Division, which is always so popular, has been increased. The new London County class for sweet peas grown within the L.C.C. area, should prove to be very interesting. The annual outing of the Society will take the form of a visit to Reading on July 8th, when Messrs. Sutton and Sons have invited members to see their general trials, as well as the Society's novelty trials. The address of the National Sweet Pea Society is 19, Bedford Chambers, Covent Garden, W.C.2.

Southport Flower Show.

THE schedule for the fourth annual Flower Show at Southport, to be held on August 24th, 25th and 26th next, is of a particularly comprehensive nature, and it is clear that the municipality responsible for the organisation of these wonderful shows is determined to spare no effort still further to enhance the great reputation Southport has already achieved by reason of the amazing success which has attended the three previous flower shows held in that charming garden city on the Lancashire coast.

This year the Flower Show Committee have pleasure in announcing that they have arranged for the British Carnation Society to hold their thirty-third show in conjunction with the Southport Show. The Society's classes are incorporated in the Southport schedule, copies of which may be obtained, post free, from the Secretary of the Southport Flower Show, Town Hall, Southport.

The total value of the prizes offered at the 1927 Show exceeds £4,000, included among which are many new trophies. The *Daily Mail* £100 Gold Challenge Cup for the best scented carnation registered with the British Carnation Society will again be competed for.

Among the numerous interesting classes in the schedule are the open championship classes for a decorated table of fruit, and for a collection of twelve distinct kinds of vegetables.

Rock and water gardens have always been a great attraction at the Southport Show, and it is anticipated that, with the additional ground which is being specially prepared for non-competitive formal gardens this year, the Gardens Section of the Show will be better than ever.

In addition to the Great Marquee—which will be still further enlarged, and will occupy about 11,000 square feet more than at the 1926 Show—there will be two auxiliary tents.

The section for the exhibition of horticultural sundries and appliances has become a very important part of the Southport Show, and, in view of this, it is interesting to note that at the forthcoming Show, gold and silver medals and certificates of merit are offered in thirty interesting classes.

Blackpool Flower Show.

THERE is no doubt that the organisers of the first annual Blackpool Flower Show, which is to be held in the new Stanley Park on July 20th, 21st and 22nd, have been successful in compiling a schedule of classes and prizes for amateurs sufficient to induce them to exhibit there in large numbers. Included in the 324 classes are 200 specially for amateurs with over 600 substantial cash prizes and a number of silver trophies, and gold, silver and bronze plaques of an original and unique design.

Traders are keen in their support, and we are assured that there will be a record number of entries in the rock garden classes, while the non-competitive entries comprise several entirely new features never before seen at any provincial show.

We are reminded that the latest date for receiving entries is July 9th.

A Gardens Guild for Manchester.

READERS of THE GARDEN already know of the work which is done by the London Gardens Guild in encouraging residents in the congested and gloomy parts of London to brighten their houses by the growing of flowers. This great social work has now been extended to Manchester. A Gardens Guild is now being formed to carry out definite propaganda and organisation activities. An inaugural meeting for the inception of the Manchester and Salford Gardens Guild will take place at the Athenæum Club, Princess Street, Manchester, which has been kindly loaned for the purpose, on June 29th at 3 p.m. Our Manchester readers are invited to link themselves up with this movement by attending this meeting. The secretary is Mr. W. G. Ayres, N.D.H., and the headquarters are the Athenæum Club, Manchester.

This Week's Work

For Gardens in the South and Midlands.

Feed with liquid manure and soot water, sweet peas, dahlias and border chrysanthemums.

Continue the summer pruning of apples, pears and morello cherries.

Protect bush fruits from birds by throwing nets over the trees.

Sow cinerarias and herbaceous calceolarias.

Stake border carnations.

Thin the bunches of grapes and layer strawberries.

Plant out celery, winter greens and cauliflowers.

Top-dress tomatoes and cucumbers.

This Week's Work

For Gardens in Scotland and the North.

Earth-up main crop potatoes.

Transplant leeks for winter use.

Continue planting Brussels sprouts as ground becomes vacant.

Net strawberries and raspberries against birds.

Shorten side shoots of red currants and burn cuttings.

Give annuals their final thinning out.

Complete the planting of begonias and other late bedding subjects.

Sow short-horn carrots for winter use.

Pinch apple and pear shoots back to six leaves.

Thin French beans to 9ins. apart and water freely.

Thin polyanthus seedlings and bed the thinnings.

SUMMER-FLOWERING TREES AND SHRUBS

THE great blaze of colour in the shrubbery comes in spring with the generality of the brooms, most of the barberries, the double gorse, the lilacs, the laburnums and flowering cherries and apples, to mention only a few of the more noteworthy. Some of the spiræas hang on a little later and the beautiful exochordas usually blossom along with the Scotch laburnums. After this there is apt to come a blank.

In favoured gardens Buddleia Colvilei is not far behind. In this country in the south and west it is fairly hardy in the open; in colder parts of the country it is surprising it is not more frequently tried as a wall shrub. Where climatic conditions permit, its successful cultivation presents no difficulty, as it is a strong-growing plant and when flowering freely, presents a striking appearance with its flower spikes of small pentstemon-like flowers, which vary in colour from rose purple to a rich dark crimson. There appear to be at least two forms in cultivation; one the lighter-coloured variety and the fine, darker-coloured form which has rather smaller flowers. This buddleia is readily propagated by striking the twiggy side growths as soon as they are firm enough to prevent damping, such shoots rooting readily under a bell glass in a cool house. Success is, however, more certain if a pot-grown plant is introduced to a greenhouse and the young growth secured for cuttings.

Then comes quite a number of the mock oranges, perhaps the very best being the species Philadelphus grandiflorus, which has the merit—as most of us think—of being scentless. P. inodorus is an allied species, though less elegant in flower and foliage. Some of the dwarf-growing Lemoinei hybrids are late to flower, notably P. purpureo-maculatus. Another very handsome (probably hybrid) mock orange is P. insignis, sometimes—especially in Continental lists—catalogued as "Souvenir de Billiard." This, like P. grandiflorus, to which it probably owns relationship, grows 10ft., 12ft. or 14ft. high. The flowers, produced as freely as on the small Lemoinei forms, are cupped and pleasingly, but not strongly, perfumed.

HYDRANGEA PANICULATA WITH ITS LARGE UPSTANDING TRUSSES OF WHITE BLOOMS. *This is an excellent shrub for planting in beds and borders for a showy display this month.*

About this season Romneya Coulteri first begins to expand its satiny, golden-stamened platters, while a great wealth of escallonias helps greatly to keep the shrubbery bright. The great stand-bys in this family are still E. macrantha, E. Philippiana and the hybrid between them, E. langleyensis. There are quite a number of new forms with Philippiana and macrantha blood—edinensis, newryensis and Donard Seedling, for instance—and these are useful additions to the shrubbery, but if I were confined to two escallonias, the sorts selected would still be macrantha and langleyensis, and probably if three were wanted, Philippiana, deciduous though it be, would be the third.

Escallonia rubra, somewhat in the way of macrantha as far as general appearance goes, is a taller grower, ultimately attaining a height of 15ft. or so. It is fairly hardy in most localities, but less handsome in flower than E. macrantha; nor does it, like that species, flower the year round. The only other kind useful for the general run of inland gardens is E. exoniensis, a hybrid of rubra parentage sent out by Messrs. R. Veitch of Exeter. This easily attains a height of 15ft. and the flowers are white or blush white. This, like E. macrantha, is a continuous bloomer and, given open weather, it is quite possible to pick sprays in mid-winter.

The ceanothuses of the americana and azureus clan, including the invaluable Gloire de Versailles, provide cloudy blue colouring at this season and, like the escallonias, they will see that the shrubbery is not devoid of blossom until late in autumn. Another beautiful shrub with the same estimable trait is the scarlet and yellow Desfontainea spinosa, which, alas! stands our winter outdoors only in favoured gardens. There is quite a batch of late-flowering brooms of which the blossoms last into July, but there is matter here for a separate article. The Spanish or rush broom, Spartium junceum, is really in a class apart, not only because it has a genus to itself, but on account of its really late-flowering and very distinctive characters. This is the only broom which is at all useful for cut flower. The golden, sweet pea-like blossoms never wilt when placed in water. The spartium is apt to prove none too hardy in bleak inland gardens unless given shelter. It will thrive in the poorest of soil and tolerates half-shade.

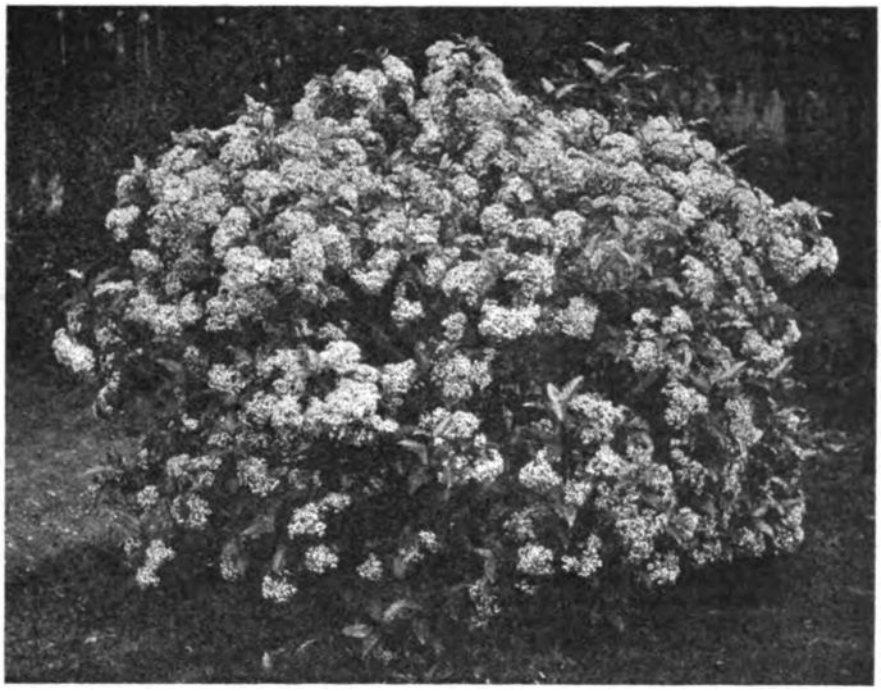
The hydrangeas are all summer and autumn flowering shrubs. The kinds usually met with in shrubberies are paniculata, including its sterile variety grandiflora, and arborescens, which produces masses of greenish or yellowish white trusses. A new sterile form of this, H. a. grandiflora, has pure white flowers, but, as in the typical plant, the trusses have a tendency to "go over" at the neck, especially after rain. The weakness of the footstalk is certainly a serious detriment to this hydrangea, which otherwise has many good points. Hydrangea Bretschneideri, which is earlier to flower than most, reminds one irresistibly of the wild Guelder Rose, Viburnum Opulus, when in blossom. It is quite hardy, but to enable

THE MOCK ORANGE (PHILADELPHUS) IS ONE OF THE BEST OF SUMMER FLOWERING SHRUBS. IT IS AT ITS BEST DURING THE PRESENT WEEKS.

Digitized by Google

t to flower freely, should have a sunny corner.

Hydrangea hortensis is hardy enough anywhere near our seaboards, and may be seen outdoors in many a cottage garden in mid-Sussex—to go no farther afield—but is unreliable at Kew. Where the type plant stands outdoors the fine variety Mariesii should also be grown. The marginal flowers of this variety only are sterile and of pleasing mauve pink colouring. Comparatively few in number, they are rendered conspicuous by their size, being often 3ins. across. There are, however, at least three forms of Hydrangea hortensis—or, at any rate, very closely related species—which will stand outdoors in many of the more favoured inland counties. These are called acuminata, Lindleyi (or japonica) and stellata, the two former with sterile flowers only at the corymb margin and the last named with curious "double" flowers.



OLEARIA MACRODONTA IS ONE OF THE BEST OF SUMMER FLOWERING SHRUBS.

The great glory of the late summer and early autumn shrubbery, however, is Buddleia variabilis. This was not always a highly esteemed shrub, and for its neglect there are two explanations. In the first place, the forms originally introduced from China were really not comparable to those collected a few years later mainly by Mr. E. H. Wilson; secondly, the necessity for hard pruning, if really fine trusses are desired, was probably not, at first, so well understood. The best forms in cultivation are (in their order of commencing to flower), Veitchiana, magnifica and superba. There is usually a week or ten days between Veitchiana and magnifica, and a good fortnight between the latter and superba. Veitchiana and superba are of much the same lilac and orange colouring, though the latter makes a finer spike. Magnifica, however, has flowers of richer colouring, a deep but bright violet purple, contrasting well with the orange at the throat.

No reference to summer-flowering shrubs would be complete which overlooked the olearias. The species illustrated on this page (O. macrodonta) is not only quite the handsomest, but one of the earliest to flower. It stands outdoors—away from a wall—in some of the midland counties, and is much hardier than is generally supposed. The same may be said of O. stellulata and the very similar, but rather laxer and larger-flowered O. Gunniana. The tenderness of the "Daisy-bush" family is largely legendary. Some of those considered most tender are at the present time hardier than many cistuses which are habitually grown outdoors, though the beautiful O. semidentata will not, at the time of writing, stand outdoors except in specially favoured districts. The fact is that it is unwise to accept evidence of a newly introduced plant's tenderness as final. Many species at first proved tender have in the long run acclimatised themselves, and this is particularly so with the olearias. A light, well drained soil and a sunny aspect should, of course, always be afforded the choicer ones. Olearia nitida, the curious semi-succulent O. nummularifolia and the truly remarkable O. insignis, which in its younger stages looks herbaceous, all stand outdoors in such inland counties as Warwickshire.

There are other families of plants which yield flower at this season, but, except the veronicas—the most useful of these is salicifolia—and the clematises, which are climbing shrubs, we have mentioned the showiest and most important, though mention should certainly be made of caryopteris and indigofera.

YELLOW DAISIES FOR THE BORDER

THE doronicums or leopard's banes are among the easiest of hardy herbaceous plants to cultivate. They are not at all particular as to the nature of the soil in which they are planted, although they favour a rather rich medium, more especially if the situation is a dry one. As for situation, that also is relatively unimportant, the doronicums being plants which will thrive in sun or shade. Every second or third year they should be lifted, divided and replanted, after digging over and manuring the ground. This operation should be performed directly the plants have passed out of flower, and showery weather should be chosen for carrying out the work, if possible; failing this, a good soaking of water should be given to the newly planted roots.

Given this simple treatment, the cultivator will be rewarded with a profusion of brightly coloured flowers during the early spring and summer months—blooms which are not only valuable for enhancing the beauty of the garden, but are also, by reason of the long rigid stems, eminently suited for cut flowers.

The propagation of leopard's banes is effected by division of the roots and by seed. Division is performed immediately after the plants have flowered; each single crown will form a good plant for the following year, and the strong growths from the outsides of the clump are the best to select for replanting. Seeds may be sown in shallow drills in the open ground from April to June inclusive. So soon as the seedlings have developed their first pair of rough leaves they must be carefully transplanted on a piece of prepared ground at a distance of about 4ins. apart. In the autumn they may be put out where they are to flower. They are useful subjects for filling flower beds, lifting them and removing them to the reserve garden when the summer bedding plants are put out.

THE LEOPARD'S BANE IS A USEFUL EARLY FLOWERING YELLOW PERENNIAL.

The following kinds are to be recommended as suitable for the great majority of gardens:

D. caucasicum.—Attains a height of from 6ins. to 18ins. and is very pretty both in flower and foliage. It flowers very early and is exceedingly hardy, being a splendid plant for shady situations, although it succeeds better in a position where it obtains the benefit of the sun.

D. austriacum.—Grows a little taller and is, perhaps, a slightly coarser plant than either of the preceding kinds. It thrives under similar conditions.

D. plantagineum excelsum.—Perhaps the best known and most useful species. It is taller growing than the foregoing kinds, and favours a rich soil. This plant usually produces a second crop of its delightful yellow blossoms in the autumn. A fine plant for the second row of the herbaceous border.

D. Pardalianches.—Grows to a height of 3ft. or even more, and produces its large yellow flowers during the summer. It is an excellent plant for naturalising in the wild garden.

T. H. E.

WHAT EVERY GARDEN NEEDS

A few simple pieces of garden furniture of good design form a valuable asset to every garden. Apart from their value in providing comfort in the garden they lend beauty to the surroundings if they are well placed.

CHARM is achieved in a garden by a variety of means that should be complementary to one another in order to gain harmony of effect. Much is determined by the choice of flowers and plants, but no garden can be considered complete without well chosen and—what is more—well placed furniture.

Choice should be governed by suitability and the question of permanency. Light garden furniture is not, for instance, suitable in a position that demands some degree of permanency, such as a seat at the end of a garden path. Broadly speaking, therefore, garden furniture falls into two groups—permanent and occasional.

GARDEN FURNITURE IN A PLEASANT SETTING.

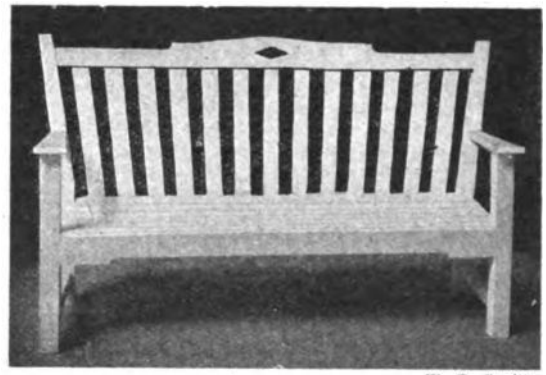
Chairs, a table and an umbrella for shade are all that is necessary to give that air of friendliness to a garden that is one of its chief charms.

In considering permanent furniture one is faced by a choice of two principal materials—wood and stone. Of the two, wood is, perhaps, the more generally preferable, as it is inviting as well as decorative. Ornament is the principal function of stone, which acquires an added attraction as time passes through the staining action of weather and the growth of moss and lichen.

Where permanent wooden furniture is being considered, we have the choice of three most suitable woods. Oak, teak and deal are thoroughly serviceable. The first two have a natural colour and grain that are attractive, and will not suffer from the effects of weather. Some people like to oil seats of these materials, but the writer's own feeling is that, in the case of oak at least, this method imparts a yellowness of tone that is displeasing.

If deal is used, it should most certainly be painted. White is the best colour to employ, more especially if the situation has a dark background; but light colours like pale yellow or blue have their place, and green of a suitable shade is always good. Seats of this kind may be obtained in shapes and styles to suit different positions. Those most in vogue are of three types—the straight, semi-circular and circular. Do not be satisfied with a piece that shows bad workmanship. "Any old thing" will not do for the garden. Furniture of indifferent character and poor manufacture is not only unsightly, but after a few years becomes unsatisfactory from the point of view of comfort.

Without doubt oak and teak are the best materials to use for wooden chairs, tables and seats, but deal falls only a little short. It is best to give seats a solid foundation on which to stand, preferably one formed of square paving, as then they are in some measure protected against the effects of damp. Although wood has its special merits, it should not be considered when stonework would look better. Stone seats may not be so inviting in appearance, but they are more durable and are generally wrought in architectural character and antique design. They are particularly suitable for corners into which they can fit snugly, or at the end of vistas, inset in a hedge of yew.



W. T. Revitt.

A WELL MADE SEAT OF SIMPLE DESIGN.

All wooden furniture should be painted white to blend in with the garden scheme.

We pass from garden furniture of a permanent character—or semi-permanent, if one prefers to keep wooden seats under cover during the winter—when we consider chairs and tables. They should be of light construction so that without much trouble they may be transferred to the house or some near-by shelter. As with seats, their design should be simple, and, as far as possible, they should conform with the former.

Chairs are to be obtained in a number of styles and materials. There are the collapsible kind, for example. These are exemplified by the plain deck-chair, which is the simplest of all. Then there are others that have arms of

Ernest R. Smith and Co.

Hugh Lane and Co., Ltd.

TWO DIFFERENT SETS OF MODERN GARDEN FURNITURE BOTH SUITABLE FOR USE IN A SMALL GARDEN.

Rustic furniture made of osier branches. *Cane furniture is both serviceable and attractive.*

Digitized by Google

good width and sturdiness, on which tea-cups and ash-trays may be laid, while an air of slight formality is imparted by a straight back. It is advisable to have flexible backs and seats of such chairs made of weatherproof material that preserves the bright striped colourings which can be obtained, and lend a gaiety to the effect.

Tables, of course, can be bought of plain design in wood, but for those who have no shady trees in their garden beneath which to set furniture in hot summer, it is well to draw attention to those tables that have a hole in the centre through which the central stake of a large umbrella may be driven.

Hammocks belong to the subject under discussion, but the ordinary sort are hazardous affairs, and it is better to consider the purchase of a swinging awninged settee.

Finally, one should consider furniture of cane and woven fibre (the latter made in gay colour finishes). Though now obtainable of excellent design and manufacture, in respect of the garden it may be put in the "occasional" category, for, obviously, it would be unsuitable to have a cane seat as terminal feature to a garden vista. But it has the advantage that it may be equally well used indoors, or in the garden house. Both in form and colour it is delightful.

Smith and Ellis, Ltd.

A COMFORTABLE FOLDING CHAIR.

Although there is a wide variety of patterns and makes of garden furniture, it would be difficult to define anything so suitable as that made from English willows. The charming autumn tints of the natural wood harmonise with the garden and in no way appear to be out of place. A few points concerning willow garden furniture might be of interest; the furniture does not require painting or varnishing. It may be left out of doors all the summer, but must be packed in a dry place during the rest of the year. To those desiring a coloured scheme, the furniture can be peeled of the bark and stained any colour. There is now a wide variety of patterns of chairs, tables, settees, etc.

SEEDLINGS AND THEIR TREATMENT

ANYONE who has raised half-hardy annuals, biennials or seedling perennial plants, knows that the seed is sown fairly thickly in boxes or special seed pans. In due course the majority of these seeds germinate, where, unless the seed was very thickly distributed, the seedling plants do not suffer from undue overcrowding if they are allowed to remain until they have made their first pair of true leaves. If, however, such a pan or box of seedlings is allowed to remain after this stage is reached, and not pricked off, the crowding which would ensue would eventually cause the whole of the seedlings to become drawn and weak in their fight for light and sustenance. Strong plants will never result from such seedlings. In fact, the formation of the pair of true leaves should be an indication that the correct time has come for the process known as "pricking off." Pricking off simply consists in giving the seedling plants a shift into other quarters, usually larger boxes or pans, in order that they may be permitted to have more room for development. The space at which the plants should remain in the boxes after this pricking off largely depends upon the type of seedling, and whether frame space is valuable. The nurseryman is rather apt to crowd seedlings in the boxes when pricking off, because he has to produce plants by the thousand, and every inch of frame space is valuable. The amateur, however, should always err on the side of too much space rather than to crowd the seedlings together. Provided the pricked off seedlings are to be given another shift into boxes before finally planting out into nursery rows, or the open border, the seedlings can be placed closer together than would be the case if they were to remain undisturbed until planted out. When a second move is to take place, the seedlings may be inserted at a distance of an inch apart, allowing 3in. each way when they have to remain in the boxes until large enough to take their chance in the open ground.

It is not usual to make nursery rows of half-hardy annuals such as asters, etc. These are pricked off in boxes, allowing sufficient space for development, and planted direct into their flowering positions. Dahlia seedlings, germinated in heat, may require as many as three moves into boxes or pots before they are planted out. The same applies to hollyhocks and similar flowers when treated as annuals. It is such things as forget-me-nots, wallflowers or other biennial plants, together with all the perennial plants raised from seed which require to be planted in nursery beds. The nursery row simply consists of any part of the garden where the plants may be planted out in a line at distances which will permit of full development without crowding. Space can usually be found at the foot of the early rows of peas, which will come off shortly after the seedling plants have obtained a root hold on the soil. Or a row or two, or every alternate row, of early potatoes may be lifted, and the plants placed in the well cleaned soil thus rendered available.

The illustration shows two such nursery rows, one of seedling violettas, and another of seedling hollyhocks, growing in ground from which, a week or so previously, crops of early potatoes had been lifted.

THE TWO NURSERY ROWS TO BE SEEN ARE EACH FIFTY FEET LONG.

The double row of seedling violettas is the produce of a small packet of seed and contains over two hundred plants.

Even with so common a flower as the wallflower, it is surprising what an improvement is seen in plants which have been lifted and planted out, over those left to mature undisturbed in the seed bed. Forget-me-nots, too, are greatly improved by such a move, there being no comparison between the plants resulting from this little extra care and those left partially starved in the original seed drills. In passing, it might be mentioned that wallflowers when planted out in nursery rows, should have their centre shoot pinched out when the seedlings have got hold of the soil. This will cause the plant to break, keep it growing in a bushy habit, and will be devoid of the "leg" so often seen in wallflower plants besides throwing twice the quantity of bloom that will be given by a plant which has been allowed to grow away naturally.

THE BUSY MAN'S PAGE

July Reminders.

PROPAGATE carnations and pinks by means of layers and cuttings.

Sow biennials, such as Canterbury bells, etc.

Transplant wallflowers, pansies, forget-me-nots and other plants raised from seed for outdoor flowering in the spring.

A final sowing of sweet peas for late flowering may be made.

Divide and replant polyanthuses.

Stake the flower spikes of liliums, hollyhocks, dahlias and any other plants needing support.

Mulch and water frequently such plants as sweet peas, dahlias, hollyhocks, phloxes, etc.

Remove fading flowers from plants generally to encourage the production of fresh blossoms.

Keep all surfaces on bed and border freely stirred with the hoe.

Cuttings of all kinds of hardy plants may be taken, and these will root freely under a hand-light in a shady border.

The budding of roses may be carried out as soon as the bark parts easily from the wood.

Trim evergreen hedges and box and other live edges to borders. Prune overgrown shrubs.

Plant celery, and earth up the early crop.

Plant winter greens of all kinds.

At the beginning of the month sow peas for a late crop, and at the end of the month sow cabbages.

Sow parsley and early varieties of carrot.

Sow lettuce and endive twice during the month.

Plant cauliflowers for autumn use.

Make the last sowing of French beans at the end of the month.

Sow a crop of turnips.

Thin out fruits where trees are too heavily laden.

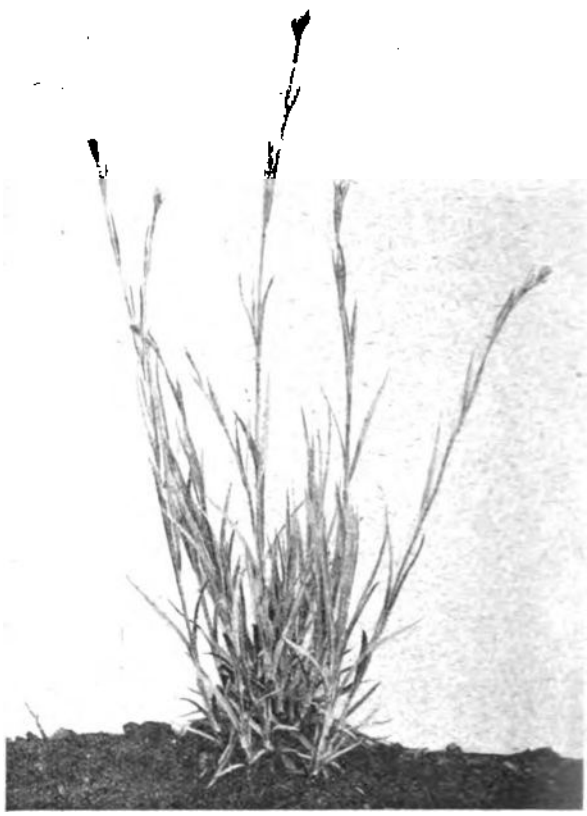
Thin out and atop the over-vigorous growth of fruit trees. This summer pruning should be done in stages, and may, with advantage, be spread over some weeks.

Many fruit trees will need mulching and watering in a dry season.

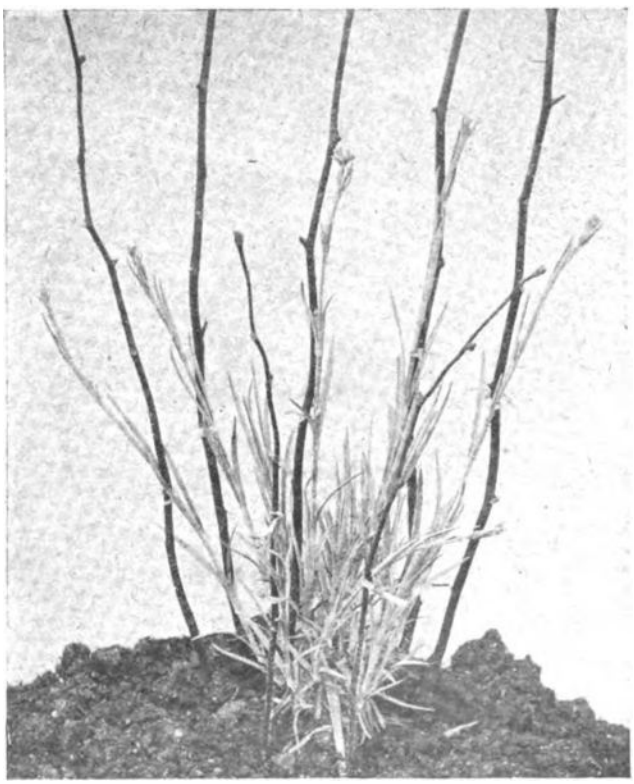
Keep a sharp look-out for the early runners from strawberry plants and layer these as soon as possible. Start the preparation of the new strawberry beds and remember that deep cultivation and a generous addition of well rotted manure to the soil will help much towards the securing of a good crop.

Staking Border Carnations.

IT is most essential that border carnations be staked as early in the season as possible, and that the stakes used do not detract from the natural beauty of the plants. Light twigs, old raspberry canes, green and natural bamboos all serve well; these are inserted close to the plant, but opening out upwards and cut off at a reasonable length. Fairly stout wire, coiled round a broom handle and then pulled out into a spiral stake, is a favourite method and quite useful where tying is objected to. Modern growers generally employ one or other of the patent carnation supports now sold, on account of their simplicity and permanence. However, the old plan, as illustrated, in which twigs are cut from the shrubbery and used, is still one of the best, because it does not destroy the natural effect of the plants and serves the purpose as well as any. As the stems extend it is, however, necessary to keep them tied, lest a storm break them off.



A BORDER CARNATION REQUIRES STAKING.
This work should be carried out at once.



LIGHT TWIGS USED FOR SUPPORTING THE GROWTHS.
These twigs can be trimmed off at the top.

Hanging Baskets.

HANGING flower baskets are always an attractive feature for the porch or veranda during the summer months. Baskets made of galvanised wire are the best, on the whole, for these are cheap and will last for years. The simpler these are in design the better, for one does not want to have the actual basket too much in evidence. Before putting in the soil the baskets should be well lined with moss to prevent the mould dropping between the wires. Rather a thick layer of moss is to be recommended, as this will help in conserving the moisture. In a general way, practically any good potting medium will do for the baskets, although very light composts are to be avoided because these will part with their moisture too quickly. It is a very good plan, after putting in the moss, to place a small saucer in the bottom of the basket. This will keep back a little of the water and prevent that sudden drying up which is so harmful to the occupants of the flower basket. Suitable subjects for the baskets are fuchsias, the ivy-leaved pelargoniums, the creeping campanulas, musk and creeping jenny (lysimachia). Care should be taken not to overcrowd the plants in any basket, and on no account must the baskets be placed straight away in their permanent positions. Until the plants show signs of having settled in, keep the baskets in some sheltered position where they will not be exposed to drying winds and strong sunshine.

How to Control Red Spider.

RED spiders are really small mites which attack the foliage of plants, both inside and outside the greenhouse. They are not easily seen, but close examination may reveal myriads on a plant and their little nests of fine web under which they live. These mites pierce the soft tissues of the leaves, suck sap therefrom, and gradually lower the energy of the plant or tree; under attack the leaves assume a woebegone and unhealthy appearance and the plant may die. Lack of moisture, bad ventilation, hot, fiery conditions, all lead to virulence of attack. Plenty of moisture and coolness are the first steps towards a cure. An insecticide also helps to hurry their departure; or soapy water, containing an ounce or two of fine sulphur per gallon, can be used; indeed, sulphur in any form is the best remedy, but liver of sulphur may also be used, 1 oz. in 2½ gallons. Always spray with force to penetrate the fine web; repeat two days later, and thereafter water and syringe the plants regularly.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Making a New Rock Garden.

NATURE planted the first rock gardens. They can be seen on any hillside. Some of the finest examples are to be found on the limestone hills of Yorkshire, where the weathered limestone forms cunning hollows in which highland plants can take shelter. Whole races of plants have adapted themselves to the conditions of a rock-strewn hillside. Saxifrages, rock roses, gentians and others are quite at home there. Artificial rock gardens find favour with many for the following reasons: The plants are all in miniature, and a large number of pretty varieties can, therefore, be grown in quite a small space; the appearance of the natural stone gives a picturesque and unconventional appearance to the garden; the succession of flowers, which can be obtained by a suitable selection, is a constant reminder of the hills where the air is clean and fresh.

Almost any kind of stone can be used to make a rockery, and I have seen a really charming rockery made from old bricks and clinkers. There are many types of rockery gardens. At Kew Gardens, the rockery is in the form of a ravine. In the Royal Horticultural Society's gardens at Wisley, the rock garden is on the side of a hill. In a small garden, the rockery can be in a corner, in the form of a mound or moraine. Build the bricks or stones in such a way that pockets of soil are left for reception of the plants. Fill the pockets with rich soil, with plenty of decayed leaves intermixed. Never leave hollows beneath the stones. A new rockery could be planted now with rock cress, aubrietia, London Pride, mossy saxifrage and violas. These will give early effects. Other easily grown rock plants are Arenaria balearica (which creeps right over the stones and bears star-like flowers), Ramondia (best for shade in a fissure), dwarf campanulas, trillium, oxalis, gentians, autumn crocus, sweet woodruff and sedums. Be careful to plant firmly, and water if the weather is dry. Weeds must never be allowed to grow, as they very soon spoil a rockery by robbing the soil of nourishment and smothering tiny rock plants. Go over the rockery every week or so, pulling out every weed, and at the same time removing any dead leaves or flowers.

Path Edges.

IN designing a garden or a flower border, some sort of edging to the path is usually made. It is possible to leave the plants in the border to grow over the edging and on to the path, but it is more usual to make a definite edging to form a frame to the picture. A grass path needs no edging. It should be slightly higher than the soil of the border, and the edge of the grass should be kept well trimmed. The border plants can be grown close to it. Crocuses, snowdrops and such dwarf bulbs are very effective grown just alongside the grass path. Old gardens have often brick edges to the paths. These can be very charming if they are moss-grown, and can be improved by clumps of aubrietia and arabis allowed to creep over them here and there. Glazed brick or tiles, glaring and unadorned, look atrocious, and were I the possessor of such a path edging I should hasten to smother the tiles with dwarf saxifrage or aubrietia.

The idea of an edging is, of course, conventional; nevertheless, a well defined line, particularly if it is a "living" one, sets off the border in a very pleasing manner, and, if it is evergreen, it often relieves the bareness during the winter months. A crazy pathway, edged with dwarf plants which just encroach on to the stone, can be particularly charming. The choice of plants need not be limited to one kind—arabis, pinks, crocus—any such subjects can be used in little groups, and their association with a crazy pavement is most effective.

For a straight edging of one kind of flowers only, there are a great many plants from which one can select a favourite. Pinks (Mrs. Sinkins), aubrietias, cerastium, violas, crocus, snowdrops, armeria (thrift), daisies, gentians, saxifrages—all such plants will make good edgings. It will be necessary to lift perennial edging plants every three years, or sometimes more often, as they overgrow each other. Also the weeds get rather troublesome as they often spring from the centre of the edging plants, and are difficult to eradicate. The best time to renew must path edgings is during showery weather, taking up the whole of the growths, and replanting small pieces with roots attached. They will have time to get well established before the spring flowering season comes again.

Box edging—now less grown than formerly—requires clipping two or three times during the growing season. It is quite a favourite with some growers, and where a new box edging is desired it should be planted now.

JULY IN THE TOWN GARDEN.

WHAT TO DO THIS MONTH.

1. *Spray potatoes as a preventive against blight.*
2. *Deal with woolly aphis—methylated spirit painted over the affected portion is a good remedy, or if the trees are badly attacked spray with a nicotine wash.*
3. *Sow Brompton stocks, forget-me-nots, Silene compacta, wallflowers and biennials, and transplant as soon as they are large enough to handle.*
4. *Layer carnations, clear withered annuals away, and plant out next year's biennials in their places.*
5. *Cut off flowering stems of delphiniums when the flowers fade, to promote second flowering.*
6. *Remove withered flowers from all bedding plants to extend the flowering period.*
7. *Thin out beet, carrots, etc., and keep the hoe going. Bend over tops of onions near the neck of the bulb so as to hasten their development.*
8. *Sow spring cabbage and stump-rooted carrots.*
9. *Water celery in dry weather, and dust with a mixture of lime and soot to ward off the celery fly.*
10. *Cut and dry herbs.*
11. *Sow salads.*
12. *Sow early varieties of peas for a late crop.*
13. *Pinch out side shoots from tomatoes, and keep tied.*
14. *Water vegetable marrows.*
15. *Summer prune fruit trees, and syringe wall fruits well with water as a preventive against red spider. Water copiously where required.*

Fruit in the Town Garden.

Summer Pruning and Training.

WHEN visiting gardens I have often been astonished at the remarkable skill displayed by amateurs in the cultivation of fruit. It is not always in the large garden that the best fruit crops are found. I saw a tiny garden in Ealing which, for its size, was a revelation in intensive fruit culture. Trained along the fence on both sides of the garden were several fine specimens of loganberries and American blackberries. In front of these was a row of bush fruits, including raspberries and black currants. Near the path were cordon apples and pears, and a number of gooseberries were trained as cordons against the wall.

It is often thought that the only important time for giving attention to fruit trees is in the winter when growth is dormant. There is no bigger mistake in the whole sphere of gardening, and for this reason: Shoots during growth are pliable and can easily be trained into the desired position. It is important, therefore, to give some attention at this season to the proper training and summer pruning of fruit trees.

The Desired End.

The object of pruning and training trees no matter what the kind, is to secure (1) an annual crop of well developed fruit and (2) a shapely and healthy bush or tree. Cordon gooseberry bushes, young espalier apple trees, or cordon pears should all have their leading shoots tied in. The laterals should be pinched back to about five leaves. Next week I will give a few hints on the summer pruning of apples and other tree fruits.

Late Dwarf Beans.

AS is well known, the dwarf bean is a rapid grower. Sow the seeds in drills 18ins. apart and thin out the seedlings to 9ins. apart in the rows. Ne Plus Ultra is the best variety for late sowing. Good results can also be obtained from sowings of carrots beet, kohl-rabi, onions, radishes, etc. But be sure in each case to sow early maturing varieties and to sow where they are to grow.

Some Garden Pests.

Onion and Carrot Fly.

Dust along the rows of plants with a mixture of soot and lime to keep the fly away. The same remedy can be used among celery and parsnips to keep away a species of fly which lays eggs that develop into the leaf-mining maggot. Paraffin emulsion is effective for these pests also if sprayed on the plants once a week until the plants are a few inches high.

Destruction of Ants.

Drive a metal rod or stick obliquely into the ground so as to get beneath any plants that are affected. Withdraw the rod and pour 2 oz. of carbon bi-sulphide (highly inflammable) into the hole, afterwards retilling it with soil. Another remedy is to use boiling water.

NOTES ON THE FLOWER GARDEN

Garden Steps.

Some Simple Types that may be Used in a Small Garden.

STEPS are becoming more common in small gardens, to which they are a picturesque adjunct, even if only in flights of from three to six. The amateur will not find them difficult to construct if attention is paid to a few important points. The following notes apply to home-made steps as distinct from the elaborate stone structures.

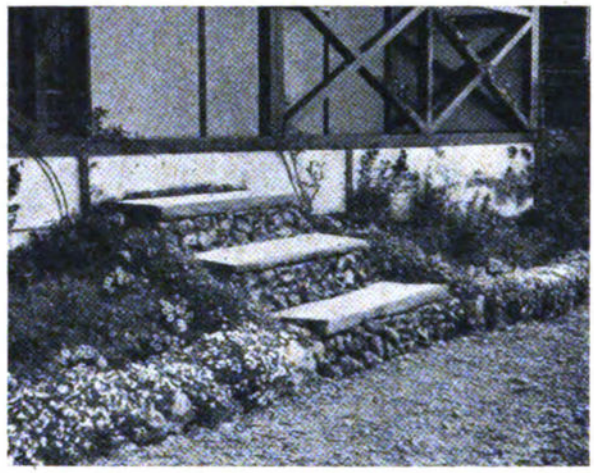
Grass is apt to be considered by the amateur as the easiest medium in which to work; nevertheless, it is not to be recommended for steps that are to be used much, as grass steps break away and subside with use, especially in damp weather, and they need endless attention if they are to be kept tidy and in good repair. If the builder wishes to avoid formality, stone or brick steps may be so constructed as to allow space for low-growing plants, as in crazy paving. All garden steps should be built upwards, the bottom one being the first constructed.

For brick steps old red bricks are the most picturesque. If they are set entirely in mortar, each step should slope slightly forward for water to drain off. Each step should consist of two courses; the lower course is best bedded in mortar, to give firmness, but pockets may be left for small plants, the upper bricks forming the "tread" in front should also be set in mortar, as they have to carry the weight when the steps are used, the back bricks may be bedded in soil to allow root room and moisture for plants.

Informal stone steps may be made from similar paves to those used in crazy paving; 18in. strips may form the tread and smaller pieces the second course, set in mortar, with earth pockets. The ground should be well prepared, and the front of the second step should abut on the back of the first, and so on, to prevent subsidence and slipping.

Picturesque steps may be made from wood, though it is best treated with creosote or some preservative to prevent its rotting rapidly and harbouring filth. If this is not done, larch is best, as it resists decay. It is simplest to use unhewn timber, two poles, about 6ins. in diameter and laid side by side forming each step. They should be laid in a similar way to the stone steps, to prevent slipping, and the crevices should be filled with soil for planting.

The best plants for garden steps are very low-growing ones, which become fragrant when stepped on, and which will survive such treatment without ill effects. It is essential to have such plants for the treads, and among them are the wild thyme, Alyssum montanum, Hypericum repens and Arenaria balearica. Seeds may be sown in fine soil in the joints, and near the back of the steps more erect plants may be used, such as Campanula pusilla and C. alba, Asperula hirta, Dianthus cæsius, small saxifrages and alpines, which are best established in spring. After planting has been done they should be watered freely, except during frosts, but after the first year the plants will need very little attention.—M. J. DEARDEN.



A SIMPLE FORM OF GARDEN STEP.

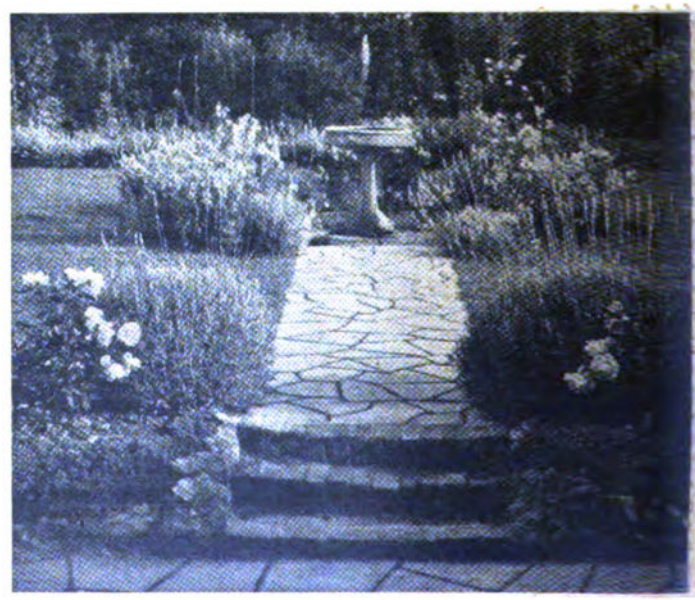
Made of paving slabs supported by cobbles embedded in cement to give a firm foundation.

An Attractive Shrub.

SOLANUM CRISPUM is commonly known as the Potato Tree, and a specimen about 15ft. high has been a source of interest during May and early June. Near London it is recommended as a wall plant; but around Chepstow it succeeds in the open without any protection, and it flowers freely every year. Four years ago a large holly tree appeared to be dying, and it was decided to plant a few pieces of Solanum crispum at the base. Now it is well clothed, and when in bloom it is quite a feature near the public highway. Being of quick and vigorous growth it is well adapted for such positions, and, wherever possible, it should be treated in this way, because it is then seen in all its splendour. Similar situations will occur to the observant gardener: old buildings, where it is allowed to ramble over the roof; and trellis-work; while for colder districts a south or west wall should be provided. Where space is available the plant can be allowed to develop; but if the area is restricted it may be pruned back in November or early spring, before growth begins. S. crispum is a native of Chile, from whence it was introduced about 1830, and although it cannot be compared with the tender S. Wendlandi in size of bloom and colour, nevertheless it is worthy of a place in every garden where accommodation can be found. With us it is nearly evergreen, and the delicate blue flowers are produced in clusters closely resembling those of the potato. The greatest display is in May and June, but occasional flowers appear till September. S. crispum is a loose-growing shrub or climber, and when in bloom it is a beautiful plant. Few, if any, can equal it at this season, owing to its graceful habit and freedom of flowering.

S. jasminoides is another of the same family, with clusters of pure white flowers. It is less rampant than S. crispum, and at Chepstow it is not quite so hardy. Both require similar treatment, and they will succeed in rather poor soil; in fact, a too liberal root run is often the cause of some plants dying during the winter months.—T. W.

INFORMAL STONE STEPS MADE OF SLABS OF PAVING STONES OF VARYING SIZES.



BRICK STEPS LOOK MOST EFFECTIVE WHEN USED ALONG WITH CRAZY PAVING.

A Fine Aquilegia.

MUCH has been written concerning the long-spurred hybrids of aquilegia, and certainly they deserve a lot of praise, but for sheer beauty and splendour a group of A. glandulosa can hardly be surpassed, especially when it is associated with lemon or orange coloured companions. Here at Castleford it has the double-flowered gorse as a background, and the combination is noteworthy. A. glandulosa is, no doubt, the garden name of this beautiful plant, and it is questionable whether the true A. glandulosa is in commerce, so the columbine under notice is A. jucunda or a variety of that species. It is most generous in its green foliage, and the flower spikes attain a height of 18ins., being at their best about the middle of May. The blooms are showy, large and somewhat spreading, the colour being a beautiful sapphire blue with white centres. When planted in isolated clumps of a dozen or more examples, the brilliancy and beauty of this species is fully revealed, and few members of the genus can excel it for health and vigour. Truly it is a garden plant of more than average merit, and it will succeed in almost any soil, but perhaps would reach its finest development in a deep, rich, cool loam. Fortunately, this desirable plant can be readily raised from seeds, and, moreover, it will reproduce itself true. Seeds may be sown at once, or directly it is ripe, and the seedlings should be transferred to their flowering quarters when small, as better results are obtained than from larger plants. If it is necessary to transplant large clumps such work must be carried out early in the spring, before growth begins.—T. W. B.

THE DAINTY BLUE AND WHITE AQUILEGIA GLANDULOSA, AN ATTRACTIVE COLUMBINE FOR THE ROCKERY.

Purple-Spiked Lavender.

Its Uses and Propagation.

AMONG the many hardy plants which will be dealt with in the coming weeks is lavender, a sweet old English garden herb which never loses one whit of its popularity. Everybody warms to lavender and wants to grow it, but perhaps most people think of it in the summer stage, whereas we should desire to have it in our gardens for its perpetual charms.

Lavender can be used in many parts of the garden with excellent effect. A lavender hedge beside a walk is an old-time garden feature, and as popular now as ever. Formal edgings of dwarf lavender are good, and this low-growing kind, which produces a crowd of heads of deep purple flowers is useful to plant here and there on the top of rockeries and on dry banks. A bush of lavender looks well in the front of a shrubbery—of course, in a sunny position, for the plant is a sunshine lover. Odd sunny corners of a garden may have a bush or two also. Then there is the white lavender, as sweet and generous in flower as the purple, and a most attractive plant.

A sandy loam is ideal for lavender, but it flourishes in any good, well dug garden soil which is properly drained. Increase can be carried out now by pulling off small, sturdy side branches and inserting them firmly in sandy soil in an open position. The soil should be kept nicely moist in dry weather, and when the divisions are rooted they may be transplanted a foot apart to grow on in a nursery bed until required for their permanent quarters. In some soils lavender needs renewing every three or four years, in order to preserve a pleasing appearance. Propagation from old plants for this purpose is easy, and should be practised every year to an extent necessary to maintain a supply of shapely young plants to take the place of the old.

The flowers of lavender are collected in July and August when they are just open, the stalks tied into little bunches which are set up to dry, not in full sunshine. Later on the individual blooms are stripped from the stalks, and they can be utilised in many ways. A useful home preparation is lavender vinegar, which has long figured as a popular remedy in fainting and in cases of fatigue. It is best made in the following way: Lavender flowers are loosely filled into a quart bottle, and a pint of white vinegar added. This is allowed to stand in a warm corner for a week or two, occasionally being shaken up. It is then emptied into a jug, the bottle cleaned out and again filled with flowers. A piece of cotton-wool is then placed loosely in a funnel and the contents of the jug poured through that into the bottle again; only the vinegar passes through, of course, and the infusing for ten days is repeated. After the second or third time the vinegar becomes heavily charged with the perfume and is ready for use. A little is poured on cotton-wool and daubed on the forehead and wrists.

BUSHES OF SWEET LAVENDER ARE PARTICULARLY DECORATIVE WHEN BORDERING THE PATHWAY TO THE HOUSE.

The Lemon-Coloured Rock Madwort.

A CHARMING companion to the well known rock madwort (Alyssum saxatile) is its lemon-coloured variety known as A. saxatile var. citrinum. It flourishes under exactly the same conditions as the better known type, and is altogether a splendid plant for the front of the herbaceous border, the rock garden, dry wall or other similar situation, while its early-flowering character renders it a useful subject for spring bedding purposes. Cuttings inserted in shaded frames immediately after flowering and carefully looked after will make delightful sturdy little plants for the following spring. —T. H.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

SUMMER has come. Of course, the spell of dry, genial weather experienced in mid-June did not suit everybody, for there were arrears of bedding out to be overtaken and without the aid of the watering can no prudent amateur would plant seedlings and other young subjects in parched land and expose them afterwards to the heat of a tropical sun. That way trouble lies. But the change came in the nick of time as it were; rain fell steadily and without intermission from dawn till dark. Alternate periods of sunshine and shower have since created ideal growing conditions, the grumblings of the past are forgotten and for the time being everybody is happy. The passing of the late frosts and the prevalence of seasonable weather have been most welcome, and there are few things in the garden that do not indicate visible signs of improvement. A number of plants that were flagging and whose future had reached an uncertain stage are now standing erect and healthy looking, seedling annuals and vegetables are coming away quickly, and roses are beginning to show bud, but the greatest difference is to be seen in the sweet peas, which are progressing up the canes and stakes by the proverbial leaps and bounds. The growth of the grass and the weeds, too, has been stimulated so that more time must needs be devoted to the routine work of the garden during the remainder of the season.

An outstanding feature of Scottish gardens this season is the promising condition of the onion crops. Amateurs have long since held a high reputation as successful raisers of those large bulbs which reach maturity in autumn, and apart from the numerous entries and keen competition witnessed at flower shows in that particular class, there is evidence of increasing interest being taken in the production of that popular vegetable by small growers. In the gardens which I have visited recently the sizes of the beds ranged from 6ft. by 4ft. to four or five times that dimension, but the area had no relation to the quality of the onions, for all were in a forward state of growth and free from disease and those ominous signs which denote the presence of insect pests. The mining classes in particular take pride in their onion bed, and as a rule they have little to learn in the way of cultural methods. It is the common practice to raise the plants from seed sown under glass early in the year, but where these facilities are non-existent the seedlings are purchased in spring, after being hardened off, from those nurserymen who specialise in that branch of the trade. The secret of success lies in a deep and richly cultivated soil followed by liberal treatment in the form of liquid feeding or fortnightly applications of artificial manure and soot during the period of growth. Such stimulants, however, are generally discontinued by the end of July, otherwise the largest and best bulbs have a tendency to split. Ailsa Craig, raised by the late Mr. Murray, gardener at Culzean Castle, is the favourite variety.

While visiting Pollock Gardens the other day I was favourably impressed with the system of growing annuals in a long border. Instead of growing the varieties in customary rows the varieties were arranged in medium-sized beds. One which attracted attention was devoted to Cynoglossum amabile, a member of the hound's tongue family, which Mr. McTavish, the head-gardener, observed deserves wider popularity than it receives at present. Although biennial by nature, it is treated as a half-hardy annual, and the blue flowers, which are produced freely, contribute to the glory of the garden from early July onward. The plants attain a height of 12ins., and being of a bushy habit, require to be spaced about 9ins. or 12ins. apart. Readers who desire a novelty should make a note of Cynoglossum amabile and give it a trial next season

The craze for the bungalow type of residence and the creation of housing schemes all over the country are in large measure responsible for the formation of strange-looking masses of stone and earth which, by a stretch of imagination, are commonly called rockeries. Some of them are suggestive of a quarry, others are arranged with mathematical precision, while a third type would almost justify the inscription "Here lies John Brown." The initial mistake that is commonly made is the selection of the wrong kind of stone. White or light coloured material seems to be popular, and the besetting sin of the builders is to use double the quantity that is actually required. The effect is impressively garish and so kenspeckle that, as a wag remarked, "the owner should experience no difficulty in identifying his domicile when he returns home late on a dark night." In course of time, when the stonework is clothed or when exposed to the elements it will assume a subdued tone that might have been obtained at the outset by substituting the more common and less expensive dark grey stones usually found in the demolishing of old buildings. Compared with a rockery a rockeried bank is much more easily constructed because it is one-sided in its formation. Good drainage, however, is the foundation for both, and as far as possible the gardener should imitate nature by placing the stones at a slight angle in the direction of their length. Set the stones firmly in the soil and, above all, avoid placing them in an upright position, as stones set on end look unnatural.

Arabis is presently in its full splendour just now and growth is so vigorous that it is difficult to keep the masses of white bloom within bounds. When planted in alternate clumps with aubrietia the colour effect produced by the combination of white and blue is very beautiful. Catmint and aubrietia also associate together and make a pretty edging to a bed or border. The latter was used very effectively in an Ayrshire garden where the scheme was composed of delphiniums and lupins as a background with clumps of campanula, aquilegia and Geum Mrs. Bradshaw in front. It was the occasion of one of the outings of the members of the Glasgow and West of Scotland Horticultural Society, which have become very popular in other parts of the country as well. Dupplin Castle Gardens were visited by Dundee Horticultural Society last month, and recently the Hamilton and District Gardening and Forestry Association spent an afternoon at Neilsland. ST. MUNGO.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Repairs to Tools.

Tools, the heads of which have become loose, are a constant source of irritation. Repairs often prove to be but temporary remedies, for the heads work loose again in a short time. To make a sound repair plug the hole with an easy-fitting piece of soft wood. Remove the brass collar from the handle and replace by three or four turns of strong wire, say, about 16 S.W.G. Bore centrally with a gimlet to provide a starting point for the spike of the tool head, which is now driven into the handle. Hold the tool head and strike the handle on a firm surface for this operation. This method will be found of value if it is desired to put a different handle on a tool head; as, for example, the long handle to the hand fork mentioned in issue for April 16th, page 256. The preliminary binding with wire is the essential point.—D. C.

A Cure for Disease in Lilium candidum.

The appearance in recent years of disease in the bulbs of the lovely Madonna lily has robbed many gardens of one of its most charming features. Three or four years ago one of the finest beds I have ever seen was attacked, and ruin seemed imminent. Two years ago, however, it was decided to lift the bulbs at resting time and transfer them to a garden some distance away. The bulbs were carefully lifted, cleansed of all surrounding soil, and thoroughly dusted with flowers of sulphur before being replanted in their new home. The year following there was growth, but no flowers, but this year they were finer than ever before, and give every indication of continuing in robust health.—H. J.

To Keep Wasps Away from Grapes or Peaches Under Glass.

One of the best and surest methods, and the least trouble, to protect grapes or peaches from the ravages of wasps is to plant a few tomato plants in pots and place them in the vinery or peach house. Wasps detest the smell of tomatoes, and if this is done it will be found that the fruit will not be eaten or disfigured by the insects which are such a source of trouble to the gardener.—G. J. J.

Scum on Exposed Masonry.

Ornamental masonry often becomes covered with a green scum. This is unsightly and difficult to remove by ordinary washing. Obtain some hydrophioric acid, and make solution in four parts of water, and wash with this. Keep the acid clear of polished surfaces. Afterwards wash with soap and water. Sandstone, marble, polished granite and fancy stones are best painted with a paste of chloride of lime and water. First wet the stone. Then allow paste to dry on afterwards brushing it off.—T. H.

A Lawn Hint.

Where the lawn runs alongside the house wall or tennis boundary net, etc., one often sees a ragged line of grass which is difficult to deal with, as the mower will not reach it. Far better than laboriously clipping this is to remove a strip of turf about 3-4ins. wide along the walls, etc., so that a hoe can be run along periodically, thus maintaining a neat appearance always, with the minimum of labour. —F. T.

THE FRUIT AND KITCHEN GARDEN

July in the Fruit Garden.

Strawberries.—Runners which have been pegged down into pots or turves will require water in dry weather. When the roots have reached the base of the pot, sever the runner from the parent plant and stand the pots in a cool, shady place for a few days. Clean the strawberry beds that have finished fruiting. Collect the straw, remove superfluous runners and hoe in between the beds. A light dressing of stable manure will greatly assist the development of the crowns upon which fruit will be formed next year.

Raspberries.—Water well if the weather is dry and renew the mulching, if necessary.

Apples.—Apply sack or grease bands to the apple trees early in the month to trap the caterpillar of the codlin moth. Look out for apple blossom wilt fungus and destroy all rotten apples.

Morello Cherries.—Tie in shoots for next year's crop and remove those not required by cutting away close to the main branches.

Netting.—The nets which have come from the strawberry beds will soon be required for throwing over the currant and gooseberry bushes. Raspberries should also be protected.

Summer Pruning.—Summer pruning which was started last month should be continued. All laterals which develop from the pinched shoots should be themselves pinched at one leaf. Trained trees can be balanced by the removal of growths and leaves from the stronger growing area, thus making for uniform development.

Watering.—If the season is dry, all wall trees will need constant attention with regard to water. A good soaking when the ground is dry is better than a number of partial waterings. Grass cuttings, make an excellent top mulch for the soil round fruit trees and help to conserve the moisture.

Mussel Scale.—This pest attacks all fruit trees and if the lice are present spray with a nicotine soap wash or weak paraffin emulsion early in the month.

Outdoor Vines.

ALTHOUGH in this country open-air grape culture is not carried out extensively, a good many people have a vine trained up a wall or, perhaps, growing along a veranda. It is to be feared that, in the majority of cases, the fruit secured is not very satisfactory, and it is certain that matters might be much improved by careful attention to a few points. Summer pruning should never be neglected, and this should be carried out before the growths have become too much entangled. In a general way one should leave only as many shoots as can be accommodated on the wall, or whatever the position may be, without overcrowding. It is best to stop all shoots one or, at most, two leaves beyond the bunch and to rub away all side shoots. Many outdoor vines are allowed to overcrop, and no spur should be permitted to carry more than one good-sized bunch. It is worth while thinning those bunches which look the most promising. The removal of a number of the inferior berries from a bunch will result in an increased size on the part of those that remain. Many outdoor vines suffer badly owing to want of water in the summer. Loosen the soil well round the main stem of the plant, and then saturate the ground with water quite often. Mulchings and the application of liquid manures will also be very helpful in swelling the fruit. Mildew is the only serious trouble which is likely to affect the outdoor vine. A common cause of this is extreme dryness at the roots, and here the remedy is obvious. Another cause is found in an ill drained position, and here the only thing is to lift the roots in the fall and to open up a trench to some depth in the bottom of which drainage material (stones, broken bricks, etc.) is introduced. Now and again an attack of mildew is brought about by uncongenial weather, and here dusting with dry sulphur over the affected parts will quickly put matters right. There must be no delay in applying the remedy, for mildew spreads rapidly and with disastrous results.

Summer Treatment of the Tomato.

Pinching and Stopping.—All laterals which arise in the axils of the leaves on the main stem should be pinched out as soon as they are formed. (The points where these young shoots arise are indicated in the illustration by the arrows.) For tomatoes outside no more than four fruit trusses should be allowed to form. When four fruit trusses have appeared, pinch out the terminal bud. Keep all side shoots pinched out as they appear. For

A STURDY YOUNG TOMATO PLANT WHICH WILL SOON NEED PINCHING AND STOPPING.

tomatoes inside, the number of fruit trusses carrying fruit may be greater. The number will depend upon the variety and the time of planting, *i.e.*, the length of time available for maturation of the crop.

Pollination.—To assist pollination go over the plants with a rabbit's-tail brush, gently brushing the blossoms.

Tying.—All plants should be carefully tied to their stakes as they grow, and when the fruit is maturing a supporting tie to the bunch is desirable.

Manuring and Watering.—Keep the tomato plants free from excessive moisture, as this is injurious to them. On the other hand, they should not be allowed to become dry. When the fruit has set, a top-dressing of well decayed stable or cow manure will be beneficial, and this may be supplemented by a top-dressing of nitrate of potash applied to the soil round the plant and watered in. The tomato needs a large amount of potash. The finest top-dressing to give tomatoes in pots or boxes is a light one consisting of chopped loam, cow manure and bone-meal. Too much nitrogen results in a soft tomato.

Feeding Tomatoes.

TOMATOES in full growth, carrying a large number of leaves and fruits are gross feeders, but it is most unwise to start off the seedlings in a rich soil medium. In such a case there is a distinct tendency towards the formation of luxuriant but comparatively fruitless growth. The best compost is mainly of good loam; this, with firm planting, means short, stubby growth and a good "set." In July, when the plants are growing fast, a top-dressing of a rich nature should always be given. This may be manure alone, or manure and soil in about equal parts, or soil enriched with artificials. Any seedsman will supply a good mixture for the purpose. Liquid nourishment may also be given and, when such a plan is preferred, the top-dressing may be reduced to a soil compost without manurial matter of great importance. Weak liquid from natural manure twice a week is a good average rule, or liquid food made by stirring 1 oz. up to 2 ozs. of fertiliser per gallon. Probably the best plan is to use natural and artificial "drinks" week about. Do not apply liquids to a dry soil; water first and several hours later feed. Do not feed, of course, for several weeks after applying a rich top-dressing.

Winter Spinach.

WHERE once the average gardener contented himself by growing a supply of the round or summer spinach only, and leaving the winter sort out of his purview, he now looks upon it as an asset, and provides accordingly. In mild winters one may have many pickings, and after a severe time it is so hardy as to recover quickly from any setback when milder conditions prevail. From July to September is a suitable period for seed sowing. This should be in drills, and may follow on ground occupied by summer spinach or early peas. Rows ought to be from 15ins. to 18ins. apart, and thinning out of the seedlings to 6ins. apart should be the rule.

From a July sowing one may gather many useful pickings in November, which will be found a change from winter greens.

I have noticed with interest during the last few years that many amateurs with quite small gardens contrive to find room for a row of winter spinach, and this is to the good; but sufficient should be grown to admit of a few leaves being picked from each plant at a time, without denuding them too much. On heavy land, a July sowing is best.—C.

A Second Crop of Broad Beans.

WHEN there is no special hurry in the matter of clearing the ground a second crop of broad beans may be secured in this way. After the final gathering of the first crop, cut the stems of the plants to within 4ins. of the ground. Loosen the surface soil round the plants well and, if the weather is dry, a few good soakings with water will be appreciated. In a very short while there will appear large numbers of new shoots which flower freely and set pods well. The beans produced in this way are on the small side, but they are very tender and sweet and in flavour are rather like green peas. If the pods are closely picked a good many dishes of beans can be thus secured almost to the end of the growing season.

Growing Fruits and Shade.

IN any summer pruning that may be carried out on fruit trees, care should be taken to leave plenty of foliage for the protection of the developing fruit. It has been shown that apples, pears, plums, etc., are very much

Digitized by Google

harmed if they are suddenly exposed to strong sunshine. The intense light and heat has the effect of hardening the tissue and reducing the elasticity, so that the power of extending in response to the action of the sap is reduced. Any young fruit exposed to the full sunshine will be smaller than one shaded by leaves because the skin will be hardened, and it is not possible that the sap can swell the specimen in the proper manner. When the growth of any fruit is complete, the matter takes on a different aspect. After arrival at full size great benefit will arise from full exposure to the sun, as this will impart flavour and colour and also bring about a perfect ripening.

OUR PHOTOGRAPHIC COMPETITION

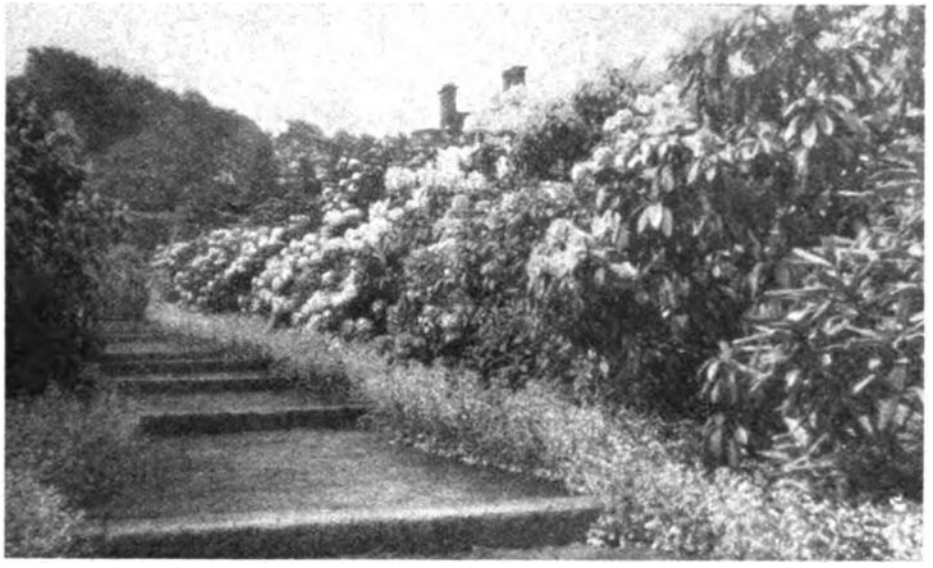
Some of our competitors seem to be under the impression that the photographs which they submit must of necessity be taken in their own gardens. This is by no means essential. As will be seen from time to time, awards are not so confined. There are beautiful and interesting garden pictures to be found all over the country, in public parks, in the gardens of friends, in wayside cottage gardens, as well as in those of more imposing character, and photographs of these are just as acceptable and likely to be instructive and interesting to other garden lovers. For these reasons they are equally as welcome as those taken in the particular garden with which the competitor is associated, though in the latter case opportunity is afforded of intimate notes of personal experience which in themselves may help other readers.

In spite of the poor, sandy soil and the north-westerly gales, this garden of blue and mauve flowers flourishes on the outskirts of a large city within a mile of the Liverpool Docks. During the past few weeks it has been a blaze of colour, with the iris, lupins, lilacs and bluebells. The beds were deeply dug and prepared some years ago, and they are periodically top-dressed. The common flag iris has been thinned out and replaced with the newer varieties with a view to prolonging the flowering season. The lupins were grown from Messrs. Downer's seeds, and young plants are grown annually from seed saved from the best blooms. The bluebells are planted in masses under the trees in the border by the busy high road.

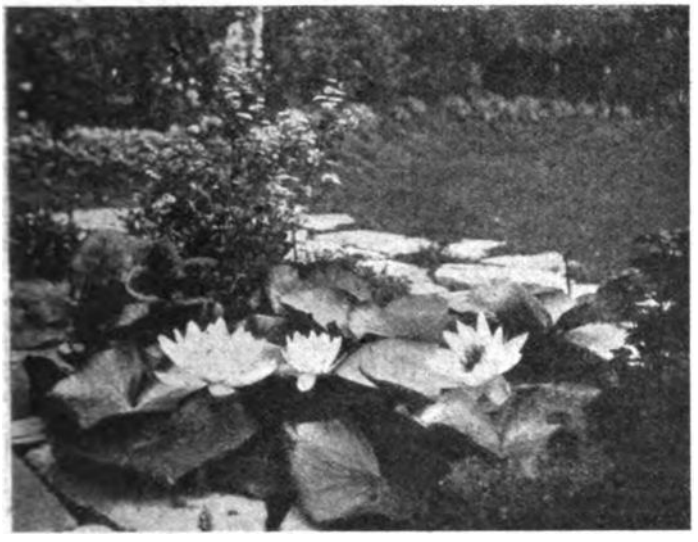
The guinea photograph sent in by MISS HOBBS, *Waterloo, Liverpool.*

This little corner of the garden makes a study in white and blue. The white iris throws up its strong heads above a plant of white saxifrage on the left, and the gentian blue Lithospermum prostratum on the right. In the background is a clump of purple aubrietia. The combination of colour tones is a most happy one and the plants have been given positions on the wall where they would look most effective. There is a secret in clothing such walls with plants so that the wall itself will gain in appearance while the plants will be shown off to advantage. The small retaining wall was built three years ago with bricks which were available from the house when alterations were being carried out. MRS. MOLESWORTH, *Crawley Down, Sussex.* Award of 5s.

Digitized by Google



This photograph illustrates the value of mass planting of rhododendrons. During May they form a perfect riot of colour and greatly add to the beauty of the pathway, which they border with their handsome trusses of flowers of all shades of colour. They make a particularly fine display. London Pride has been planted as an edging to the path, and its feathery sprays of blossom look particularly attractive in front of the rhododendrons. T. HOWARTH HEAPS, *Keighley.* Award of 5s.



These water lilies are planted in a wire basket and placed in half a barrel with charcoal at the bottom. This is kept full of fresh water and the lilies have been most satisfactory. There are three of these barrels surrounded with paving stones and choice little moisture-loving plants. It is an idea which many amateurs may like to carry out in small space. MISS E. WINGFIELD, *Exeter.* Award of 5s.

The photograph shows a small group of plants which we call cultivated hyacinth bells. They are like an ordinary bluebell to look at, only these are in pink and white shades and require no cultivation whatever. They are exceedingly useful for filling up any gaps in the shrubbery where nothing else will grow successfully. In front of a greenhouse they are exceedingly attractive. MISS SMITH, *Ecclesall.* Award of 5s.

These two photographs illustrate different ways of draping a rustic pole, or the front of a veranda. On the left is seen Clematis Nellie Moser with individual blooms some 6ins. to 7ins. across. It looks very attractive surrounding a cordon plum. It is one of the most decorative of clematis varieties. The plant is now three years old. C. C. UNDERHILL, *Canterbury.* Award of 5s.

On the right is seen a very fine plant of Wistaria covering one of the uprights of a veranda in the front of the house. There are few more useful subjects for adding beauty to the house wall than this elegant shrub. MRS. K. CLARK, *Rye.* Award of 5s.

VEGETABLES FOR WINTER USE

IT may appear out of place or at least premature to write about winter crops while summer has only begun, but it is one of the elementary principles of a gardener's life and work that he has constantly to be looking ahead and anticipating the wants of his household in respect of the food supplies that are produced in the garden. From a purely economical point of view it is even more desirable to raise vegetables for winter use, when market prices are usually high, than to grow them in summer when they are more plentiful and cheap. It may, however, happen that the limitations of space prevents many amateurs from participating in the late culture of vegetables to the extent that they would like, but in many gardens the ground is not utilised to its full capacity, for there is much that may be done in a practical way by double cropping the land, which simply means growing a late crop of vegetables on the ground previously occupied by early cabbage, potatoes, peas, etc.

In the selection of vegetables for winter use, consideration must be given to family tastes and prejudices. For instance, there are people, young folks especially, who do not like leeks; savoys and kale are not so popular as they used to be, and broccoli is an uncertain crop in certain parts of the country. But be that as it may, the gardener will require to make up his mind at once as to the kinds of vegetables that are to be grown, as sowing and planting are obligatory, at the very latest, in the early days of July, and no time must therefore be lost.

Brussels sprouts are not only popular, but they are a profitable winter crop. Seed sown outside in spring will have produced hardy young stuff that is ready to be transplanted, or plants may be obtained from a local nurseryman. The distance between the rows should not be less than 2ft., and 18ins. between the plants is sufficient space for most varieties. In common with other members of the brassica family, they like a good, rich soil, but it must not be heavily manured, otherwise there is a tendency on the part of the plants to produce loose instead of firm buttons. Keep the ground moist in hot weather, and any stimulant in the form of nitrate of soda or manure water should be given sparingly and at fairly long intervals.

Kale is similarly treated. As there is a great difference in the quality of this vegetable, try to obtain a dwarf, curled variety. Tall-growing sorts are sometimes distinguished by coarse leaves, which are not suitable for table use.

When sown late, carrots are less liable to the attack of the carrot fly maggot. The ground should be deeply dug over and, as the winter roots are larger when they reach maturity than those intended for summer use, thin out the seedlings to 3ins. Always retain the strongest specimens and make the soil firm after it has been disturbed in the process of thinning.

The leek is one of the most wholesome and hardy of winter vegetables, and its food value is approximately the same as the onion. Strange to say it is not prized so much in the south of England as it is in the north and also in Scotland, where it is grown to perfection by amateur gardeners, both for exhibition and culinary purposes. Leeks crop well when transplanted in ground previously occupied by a crop of early potatoes. After forking the soil and removing the weeds, dibble a series of holes to a depth of 6ins., in rows sufficiently wide to permit of the free use of the hoe, and allow a space of 3ins. between each plant. When the plants are put in, do not fill up the holes with soil, but give them a good watering instead. This treatment serves a two-fold purpose. It supplies moisture to the roots and carries down sufficient soil to establish the plant, leaving the remainder of the space to be filled up gradually by the summer rains. Occasional applications of manure water stimulate growth, but care must be taken to produce medium sized leeks that are preferred in the household to the bulky specimens with coarse green leaves. In a series of trials at the Norwegian Vegetable Research Station, near Oslo, which extended over a period of three years, it was found that there was some relation between flavour and frost resistance, on the one hand, and the colour of foliage on the other. Varieties with grey blue foliage had a milder flavour and withstood winter conditions best. Those with green or yellowish-green foliage have a stronger flavour and are less resistant to frost, but this may be mitigated by earthing up. Of the leeks on trial, Suttons' Prize-taker headed the list, and the others which proved superior were Dobbie's Champion and Lyon Selected. These are all good for autumn and winter use.

Every housewife values parsley, and as it is liable to be injured by frost a pinch of seed sown in summer will provide plants that can be transferred to a frame in late autumn. An alternative method is to select a few plants from the main crop in the garden and winter them under glass.

Like all other members of the cabbage family, broccoli takes a lot of nouriahment out of the soil and the ground should, therefore, be deeply dug and liberally manured. Planting may be done in July, and as the leaves flag readily in warm weather the operation should be carried out on a dull day and when the ground is moist. Firm planting and plenty of moisture are essential to the welfare of broccoli.

The garden swede is a useful winter vegetable that is being more generally cultivated by amateurs. This type is smaller than the field-grown swede and is not so coarse in the texture, while the flavour is considered to be superior to the ordinary turnip. Seed may be sown as late as the beginning of August in ground that was previously occupied by early peas or potatoes. After the soil has been got into a good tilth by hoeing and raking, draw out drills 2ins. deep and from 15ins. to 18ins. apart. As turnip seed germinates freely the seed should be scattered lightly, otherwise considerable waste will take place when the seedlings are thinned out to 9ins. or 12ins. apart. A point to remember is that while sunshine suits the turnip, a dry soil is the chief cause of failure. During periods of hot weather, such as is experienced towards the end of August and early September, it must have moisture and this can best be provided, not by simply watering the surface, but by a good soaking of water plus frequent hoeings between the rows.

Other winter vegetables, such as beet, parsnip and celery may also be grown if there is space available. K. G.

WHAT OUR READERS SAY

THE POISONOUS PROPERTIES OF PRIMULA OBCONICA.

SIR,—With reference to the poisonous properties of Primula obconica, it might interest you to know that I am one of the "few supersensitive individuals" who suffer without actually touching the plant. Finding it caused a bad rash on hands and arms, lasting from ten to fourteen days, I wore gloves next time I had occasion to handle the plants and was careful not to let them touch my face. Next day my whole face was covered with a rash—ears, neck and chin included, and one eye nearly closed up with swelling. I had twice to go to the doctor, as my eye was swollen and inflamed for over a week.

This surprised me the more in that hitherto I had considered myself immune from the irritation, so think they are poisonous in the spring, in the height of flowering time.

I find that Vaseline rubbed in on face, neck and arms affords complete protection, as I have since handled the plants with perfect safety.—(MISS) ROSAMOND DOWDING, *Lancs.*

SIR,—In the Service Bureau column of the June 18th issue, you answer a query about Primula obconica. May I relate my personal experience of its terrible effect which occurred some years ago? I became attacked by a rash that was most irritating upon my chin and neck. This broke out into large blisters which, besides being painful, were most disfiguring. After consulting several doctors in vain, I learned the real cause from a gentleman whom I met accidentally and who was a botanist. He told me that the whole trouble arose from the fact that I had around my rooms many Primula obconica plants, the flowers of which I occasionally pinned in my dress near my neck and chin. After every plant was destroyed, I became quite free from my misery, but the scars from the blisters have remained till now and will never disappear.

I relate all this to your readers, for no doctor ever suggested the real cause, and the trouble cost me, in money to doctors, etc., over £20, and in pain and irritation and sleepless nights much misery and ill temper to all around me.—A "GARDEN" READER.

ALPINES IN SMALL GARDENS.

SIR,—There are no plants out of which the possessors of small gardens can obtain more pleasure and interest than the alpines, but, unfortunately, so far as my observation goes, the so-called rock gardens are more often eyesores than things of beauty. The name, perhaps, has something to do with this: a rock garden must be a garden made of rocks, and so the said rocks are dumped into a bank wrong way up, or made to form a kind of cairn in the middle of the little lawn.

It would be much better to set apart a small portion of the border, facing south, put in a foundation of clinkers, then a few good rocks and a scree mixture a foot deep, and to grow nothing but the very best alpines, Dianthus neglectus, Saxifraga Burseriana, Viola gracilis, etc.; and if the work is properly done from the start, there is no reason why the owner should not be able to grow the more difficult species which have failed in the gardens of his richer neighbours.—C. G. FIELD-MARSHAM.

[We can only say that we agree with the opinions expressed by our correspondent.—ED.]

A GARDEN WHEELBARROW.

SIR,—I note in the June 18th issue of THE GARDEN a letter signed "C. J.," drawing attention to the lack of a suitable standard wheelbarrow. He requires one that guarantees "a maximum load, ease of filling, ease of tipping, and the weight when full should rest on the point of balance rather than on the arms and shoulders of the person operating the barrow."

About fifteen months ago I constructed such a barrow of English elm sides and English ash wheel and strines. The wheel is quite standard, but the body is carried out over the wheel, the front and tail boards are removable for ease in tipping, and the sloats

Digitized by Google

are stub-mortised into the strines, thus avoiding the too common failure of fracture at the mortises.

Very little more than half the manual effort in wheeling the load is required, as contrasted with the older type. In a levelling and excavating job in my own garden I found the trouble of designing and constructing this barrow more than repaid by the ease with which I removed about 120 loads of clay and stones.

I must emphasise, however, that the path to be travelled must be hard and dry, and "C. J." should be warned that this type of barrow, with a full load, is not so manageable when not on an even keel. This is due to the fact that the centre of gravity of the load is farther from the operator, and therefore less under control.—G., *Harpenden.*

ALLOTMENTS MADE BEAUTIFUL.

SIR,—I should like to express my appreciation of the Editorial in one of your recent issues, on the subject of "Making Allotments Attractive and Beautiful." We should claim more public interest in the working man's allotment if those who are in charge of the letting would only take trouble in the selection of suitable tenants and choose those who take a keen interest in gardening. The modern tendency is certainly to have flowers as well as vegetables as in my own case. I grow half and half, and my garden took the first prize last summer out of 600 allotments, which speaks well for this district, when it is remembered that many of the allotment owners work in the mines. We find plenty of enjoyment in cultivating our gardens. Since I started introducing flowers two years ago, there are now about twelve of our members who have a small flower garden and have introduced ornaments and furniture to add further beauty to the allotment ground.

My own flower garden consists mainly of roses—about fifty of them—with sweet peas on either side of the walk to the summer seat, with a bed of gladioli bordered with snapdragons and violas, with an edging of white alyssum, and last year it looked particularly fine.

I may say we run an open show in connection with our gardens. This is our third year, and a very good show we have for a small village. At present it is in a very flourishing position.—B. HALSTEAD, *Thornhill.*

HOW NOT TO GROW DAFFODILS.

SIR,—The note in your issue of June 11th, by an Oxford correspondent headed "A Daffodil Classification," is a little difficult to follow. The only possible way to deal with it is to pick out a point or two and answer them. He says, for instance, that "Weardale" only attains to "perfection" when pampered with all the nurseryman's arts. It requires no "art" to grow Weardale; let your correspondent plant it on a cool, deep soil, enriched with a little bone manure, and it will thrive and give him of its best; it wants nothing more. It is the taking of a little common-sense pains that brings out the best in the daffodil, or, for the matter of that, any flower we grow. In my experience, the daffodil hardly ever goes back, *i.e.*, reverts to something similar in appearance to some of its (inferior) ancestors, unless treated just anyhow and that is, I suppose, what your correspondent means by planting it, as he says, in "natural" conditions and leaving it to multiply. His concluding sentence is so characteristic that it is worth quoting in full. He writes: "It may be that it would take, not thirty, but a hundred years for this retrogressive horticulture to produce interesting results. Even so, it is worth undertaking." I emphatically disagree. Even if, as is sometimes argued, we do too much for posterity, because it has done nothing for us, I fail to see why we should treat it so badly as your correspondent suggests. For myself, I shall endeavour to continue to improve the daffodil, on useful, progressive lines, and with no desire to interest those who come after us in the fantastic and unprofitable way proposed.—F. HERBERT CHAPMAN.

WORK IN THE GREENHOUSE

Cinerarias—The Amateur's Flowers.

IT would seem that it only requires a very short step into complete hardiness, could it be taken by the cineraria, for it will stand a cold temperature that verges upon freezing point and if slightly attacked by frost, the plant will send forth fresh shoots, providing the roots are not injured. Indeed, it is essential that the plants should be grown under cool conditions all the time, introducing them into heat only as flowering is required. The amateur with no heat at command can grow cinerarias providing he can keep out frost from his glasshouse or give the plants sufficient protection from its influence.

As a rule cinerarias are required to bloom in spring and early summer, but flowering is possible at other times of the year, if wanted; a batch of seedlings may be pushed ahead or held back as desired. The seeds, however, are usually sown during June and July; the amateur would do well to sow early, taking advantage of a warm spell to get the seeds to germinate—there is no difficulty about that, nevertheless, but a good start is a factor of success where "cool" culture is the rule.

Sow the seeds in well drained pans of light, rich, peaty soil, covering the seeds but lightly. When up, prick out the seedlings, or pot them up into the smallest size pots, and shift on as required. All this should be done in a greenhouse or frame that is not exposed too much to the sun. In many localities the seeds may actually be sown out of doors in July, if care is taken to pot up the plants in September.

The after-care of the plants consists chiefly in keeping them neither too moist nor too dry—the latter is probably the worst trouble, for a well drained pot will prevent excess of moisture. Although necessary for their well being, cinerarias cannot stand the too direct attentions of the sun, and show signs of great distress if the sunshine is allowed to fall upon them for a length of time. Greenfly is one of the chief pests of this plant.

As a pot plant for table decoration, the cineraria is excellent, for it stays in good condition of flowering for quite a long time. For this purpose, tall, much branching plants are not desirable, but well grown compact specimens should be aimed at. This is all to the advantage of the person who has little or no heat at command in his greenhouse, for he can ensure the steady, continuous growth that will make the moderately-sized plants necessary for indoor decoration. Never allow the plants to flag or receive a check through neglect. Keep them under shady conditions without depriving them of light and plenty of air, and for several weeks under management, a succession of blossom in mass formation will be the result during May—earlier or later, as desired.—H. A. DAY.

A FINE DISPLAY OF CINERARIAS IN AN AMATEUR'S GREENHOUSE.
Seeds should be sown this month for next year's show.

Summer Treatment of Perpetual Carnations.

First Year Plants.

ALL perpetual-flowering carnations intended for winter blooming should be in their flowering pots by the beginning of July. The size of the pot will depend on the variety, but it is rarely necessary to use a pot larger than 7–8ins. The compost for the final potting should be: 4 parts good lumpy loam, 1 part leaf-soil, 1 part manure, ½ part rubble, ½ part burnt ash, with a 5in. potful of bone-meal per barrow-load of compost. Crock the pots well and pot firmly. Do not bury the stem.

Place the pots in a frame where they can be protected from heavy rain. Do not water

Digitized by Google

on dull days, and encourage growth as freely as possible. Allow plenty of space and a free circulation of air. The plants should not be watered unless they are dry, when the pots should be filled to the brim with the water.

Stake the plants as required. Syringe forcibly under the foliage daily, if fine, at about 4 p.m., to keep down red spider. Feed about once a fortnight with dilute manure water, and also give guano or some recognised brand of carnation manure. Pinch back to six pairs of leaves the shoots thrown up from the first stopping. Do this at different times to obtain a succession of bloom.

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry.*

We have selected the following enquiries with their answers, as being of more general interest, and therefore worthy of publication.

Cutting Back Tree Lupins.

Will you kindly tell me whether tree lupins should be cut back. I had a very fine yellow specimen which was a mass of bloom 5ft. high last summer, in the autumn it was cut back to the root and this year it has only grown about 2ft. and borne a few miserable spikes of bloom, besides looking very unhealthy. Also I should be glad to know when planning a new border of lupins, delphiniums, Michaelmas daisies, etc., whether better results are obtained if new plants are planted in the autumn for blooming the next summer, or whether in spring for blooming the same season.—T. G., Streatham Hill.

Tree lupins are cut, of course, but such drastic pruning as that to which you refer would have very bad results. Herbaceous subjects are best transplanted in the autumn. Delphiniums should be transplanted early in the autumn or late in the spring. Do not plant them in the winter time.

Old Rhododendron Bushes.

I have two rhododendron bushes in my garden. Both are very twiggy, with foliage or flowers only at the ends of long, crooked twigs; one is bearing flowers fairly well, though some of the buds are decayed; the other has only one bloom, and gives signs of putting forth only poor leaf. Can you tell me what pruning, manuring or other treatment they require, and when.—R. C., Ilkeston.

Early April is the best time to cut rhododendrons very hard back into the old stems. All that can reasonably be done now is to shorten the longest of the straggling branches to improve, at least, a little, the appearance of the bushes. Pick off the old flowers when they fade. Clean the ground beneath the bushes now and lightly prick over the surface soil. Do not dig it, as that would destroy the surface roots. Give a mulching of leaf-mould and water once a week for about eight weeks with Peruvian guano dissolved in rain water, or at least, lime free water.

Propagation of Berberis stenophylla.

The enclosed cutting is from a bush of Berberis stenophylla, which is about 10ft. high. Will you please inform me how I can increase the bush. That is, what sort of cuttings should I take? I have no greenhouse or frame. Also, when should the cuttings be taken? Flowering finished about two weeks ago.—B. H., Waltham Cross.

Cuttings should be made about 2ins. to 3ins. long of this year's new shoots, taken off with a very thin heel—or skin—of old wood, just at the point of union with last year's growth. The cuttings should be inserted in a box of sandy soil in August or September. The box should be at least 1ft. deep, allowing 4ins. for drainage, 4ins. for soil and 4ins. at the top for the cuttings, above the soil. Cover with a sheet of glass to keep the cuttings close and moist.

Plants for a Shady Greenhouse.

I have a large greenhouse at the back of my house. It is very light, but the sun does not reach it until late in the evening. Could you give me a list of plants, flowers, etc., to grow in boxes and pots in this non-sunny position? I could make arrangements to have it heated for the winter.—T. F., Newcastle-on-Tyne.

You will find the following kinds of plants very useful for the position you mention

Our Photographic Competition

1. All photographs sent in must be taken by the reader or submitted with the consent of the actual photographer.
2. Prints should be on smooth surface paper and preferably in black tones, and can be of any size. Figures may be included where these are helpful to the composition.
3. Prints need not be mounted and negatives must not be sent.
4. The name and address of the sender must be clearly written on the back of each photograph, together with a few explanatory words, such as the names of the flowers, where grown, when planted or sown, or anything which gives point or lends interest to the picture.
5. Each photograph must be accompanied by a coupon, to be found on page xi, and a piece of cardboard should be used to prevent damage in the post. Envelopes should be marked "Photographic Competition" on the outside and addressed to The Editor, THE GARDEN, 20, Tavistock Street, Covent Garden, W.C.2.
6. A stamped addressed envelope must accompany all photographs. The Editor will endeavour to return those which are considered unsuitable. If this rule is not complied with, prints will not be returned.
7. The Editor will not hold himself responsible for photographs lost or damaged in the post or otherwise.
8. No correspondence can be entered into.
9. All photographs published will become the copyright of THE GARDEN.

To the reader who sends in the photograph which the Editor considers the best of the week a prize of 21s. will be awarded. For all other competition photographs published 5s. will be paid. Payment will be made about the 7th of the month following date of publication.

Tuberous begonias, fuchsias, calceolarias, cyclamen, cinerarias, primulas, heliotrope. Nerium Oleander, streptocarpus, mignonette. A few azaleas, spiræas, Deutzia gracilis and of course, bulbs, such as narcissus and hyacinths for autumn and winter use, would keep the structure bright all the year round.

What to Plant Under Fruit Trees.

Could you inform me what could be planted with advantage in a light, dry soil under fruit trees—in the flower or vegetable line—everything I have tried so far "bolts." Also what is the best time of year to re-arrange an herbaceous border? Autumn or early spring?—R. H., Reading.

Gooseberries and black currants do best between rows of fruit trees, also lily of the valley, some irises, turnips, radishes, lettuce and spinach. It is not wise, however, to have any crops nearer than 2ft. of the fruit tree stems. The re-arranging of the herbaceous border should be done in the autumn if the soil is light, but early spring would do quite well if the soil is heavy. If you like bulbs, narcissi, would do well under the fruit trees. They should be planted in the autumn.

Anemone apennina in a Town Garden.

Last autumn I bought bulbs from a well known firm and planted them early in October in my rock garden and herbaceous border, both facing south. Most of the bulbs flowered very well, but Anemone apennina, after a lusty show of leaves, only produced one flower from a dozen bulbs. Can you give me any hints for next season? My garden is in the town, but Gentiana verna flowered well.—M. H., Nottingham.

Anemone apennina, like most other varieties thrives best in a compost in which there is a lot of rotted leaf-soil. The plants are surface-rooting, so that portion of the soil should be good. A covering soil one inch deep is sufficient. So treated the plants should do well, and if you can get clumps properly established they would flower most profusely.

New Plants at Vincent Square

THERE were so many plants and flowers before the two sections of the Floral Committee at the Royal Horticultural Hall, Westminster, on June 21st last, that the large room was almost a flower show in itself.

To the garden lover, perhaps, the best new plant was the Alstroemeria hæmantha B. Ladhams. Quite a number of good seedlings from the Chilian species have been raised during recent years, but none more beautiful than this lovely soft pink coloured variety which was shown by Messrs. B. Ladhams, Limited. Lilium concolor Dropmore variety was a close second to the alstroemeria. The normal flowers of the Chinese orange lily are somewhat rusty in colour, but this new variety is a glowing orange-red. We were told by Mr. Amos Perry, who showed the spikes, that it was raised by a lady in Manitoba, who, having an affection for the Buckinghamshire garden which is famed for its collection of coniferous trees, named it Dropmore variety. It is of comparatively dwarf habit, for Mr. Perry's plants were only 2ft. in height.

Calceolaria sp. A.C. 405 requires a specific name. It was raised from seed recently collected in the Andes by Mr. Coomber. Mr. Clarence Elliott told us that several plants withstood last winter quite unprotected, so it is comparatively hardy and should prove to be valuable for summer bedding and for the lower parts of the rock garden. Although it has a certain superficial resemblance to Calceolaria amplexicaulis, this new species is distinct in its large ovate leaves and harsh texture and in the bright yellow flowers, having lobes around the pouch. It is evidently a very free-flowering plant. Two very good single-flowered herbaceous peonies received awards. Globe of Light, shown by Messrs. Kelway and Son is a large flower of soft pink colouring, rather paler at the margins and has a large cluster of pale yellow filaments. Orion, shown by Mr. W. B. Cranfield, is a little smaller, but substantial and rounded. The petals are of rich ruby colour and it has a compact cluster of golden filaments striped with ruby.

THE GARDEN

VOL. XCI.—No. 2901. JULY 9, 1927. PRICE TWOPENCE.

GROW MORE IRISES

IN this number readers will find a few pages devoted to irises and their cultivation, and it is hoped that this special iris number will encourage many of our readers to take up the growing of this fine garden plant in real earnest. Within recent years, owing to the untiring efforts of such pioneers as the late Sir Michael Foster and the late W. R. Dykes, the iris has been greatly developed and improved, till to-day there exist varieties and different types of the graceful *fleur de luce* suitable for every taste and almost every situation in the garden. We have not as yet reached finality in the development of the flower. Much work is at present being done by many of our large nursery firms which specialise in iris culture, and from year to year new sorts appear which outshine their predecessors.

There has been one aim in this development of the iris, and that has been to make it an attractive and easily grown garden plant fit to take its place alongside of our most beautiful summer garden flowers. That aim has been accomplished. It is now a plant to be grown by every amateur who desires his garden to look its best during the summer months. It is handsome in flower and foliage, offers a wide range of the most beautiful shades of colour, and in addition, what is probably of more importance to the beginner in gardening, it is a plant of simple culture. There is no place in the garden into which the iris will not fit. Varieties can be found for the general herbaceous border, others for moist situations, along the banks of a small pond or stream, while still more make first-rate plants for the rock garden or for edging a small flower border. While they are particularly decorative in the garden either growing by themselves or in association with lupins, they are most effective when used as a cut flower for house decoration.

As regards cultivation, readers will find detailed instructions given in the cultural article, but a word as to the time of planting may not come amiss here. Many authorities advocate July planting, and the advice is excellent provided good growing weather could be guaranteed after planting. There are few plants, and the iris is included, that can withstand a period of drought and heat after planting and come through successfully. For this reason therefore, let the planting, transplanting or division of the iris be governed largely by weather conditions, and as these are often uncertain, it will be found better to withhold planting until later on in the summer, say, at the end of next month or during September, the earlier the better. At this time the weather conditions are more favourable for the plants becoming readily established in their new positions. If this happens to be a wet summer season, then planting may be carried out earlier. Order now to ensure early delivery of the plants, but plant at the end of next month or the first or second week in September. You will find that success will lie that way. The question of soil and situation is important, and the intending grower would do well to pay careful attention to the remarks on page 446. There has been a prevalent idea with many gardeners in the past that because our native iris, I. Pseudacorus, grows in boggy places and along the edge of streams, that all irises want abundant moisture. Such is a mistake. There are certainly a number which revel in moist places, but there are others such as the section of the bulbous irises that will only succeed in light well drained soil.

When one comes to sections and varieties it is manifestly an impossibility to make a choice. Every gardener has his own ideas and tastes and a selection is best left to the grower. But for those amateurs who may find a suitable choice of varieties of irises for their garden a matter of some difficulty we give the following list of good all-round standard sorts that will succeed in every garden if the cultural hints given elsewhere are followed. These are all inexpensive, and we understand that stocks are available of each kind. They may be planted from now on until September. The colours and time of flowering are given to assist the grower in the planting and arrangement of each individual variety so that the very finest display will be obtained next season.

May-flowering.—Albicans (pure white), Chateaufort (a fine deep claret), Argus (violet and purple, a great improvement on the old blue flag), and Zwanenburg (glistening bronzy fawn and old gold.

June-flowering.—Varieties with white standards and blue or purple falls: Nakomis, Miss Willmott and Rhein Nixe. Varieties with lavender to purple standards and mostly rich purple falls: Alcazar, Archeveque, Monsignor, Perfection, Radiance and Tamerlane. Soft blue and lavender to rosy crimson varieties: Astarte, Caterina, Crespuscule, Ed. Michel, Her Majesty, Lohengrin, Oriental, Rhodda, Ringdove and Wyndham. Varieties with standards soft blue to purple and falls crimson, rose or purple shot with gold, all beautiful: Eldorado, Grevin, Le Vesuve, Mary Garden, Mount Penn, Marian Loat, Prosper Laugier, Quaker Lady and Queen Mary. Varieties with standards in shades of yellow, falls mostly crimson and bronze: Lorelei, Marie Corelli, Minnehaha and Mrs. Neubronner.

This Week's Work

For Gardens in the South and Midlands.

Layer border carnations and strawberries.

Make a final sowing of dwarf beans, stump-rooted carrots, endive and parsley.

Plant out cabbages, Brussels sprouts, broccoli, and earth up late potatoes.

Continue summer pruning of apples, pears and bush fruit.

Remove spent flowers from rhododendrons, lilacs, spiræas, herbaceous perennials, sweet peas, etc.

Keep the herbaceous border well hoed and all plants securely staked.

Top-dress cucumbers in frames and thin out the growth.

Cut back aubrietias, arabis and other early-flowering rock plants.

Spray potatoes with Bordeaux mixture to keep disease in check.

This Week's Work

For Gardens in Scotland and the North.

Increase saxifrages by cuttings or division.

Sow seeds of herbaceous plants in border or frame.

Give perpetual carnations that are to bloom in November a final pinching.

Plant violets in a moist shady border.

Thin or cut back philadelphus as soon as the flowers fade.

Mulch young plants of raspberries, currants and gooseberries with manure.

Sow East Lothian stocks for spring or summer bloom.

Transfer pot roses that have finished flowering indoors to a sunny spot in the garden.

Plant broccoli in very firm ground.

Dress asparagus beds with agricultural salt or seaweed.

Digitized by Google

AN IRIS GARDEN FOR EVERYMAN

EVERY garden lover who has kept in touch with recent developments in horticulture must have been attracted by the expansion of possibilities for garden enjoyment offered by the advance that has been made in iris culture.

Twenty years ago the iris was a plant that was introduced into one's garden with little enthusiasm, or omitted without regret. To-day the genus takes its place with those flowers that one must have, such as roses, carnations, delphiniums, etc. Moreover, such a wealth of material is offered and such a wonderful range of colour and form, owing to the progressive efforts of the hybridist, that there is a justifiable inclination to devote some portion of the grounds mainly or exclusively to the cultivation of irises. Such efforts will, naturally, be in proportion to the total area of the garden, but there are few so small that their owners will wish to be without an iris corner.

To the specialist, that is, the man who grows irises simply for themselves, a rectangular border will suffice; but to the gardener who desires to use his plants in such a way that he will get the maximum of pleasure out of them by associating them with other subjects in such a way that each derives some added attraction from the other, something more is necessary.

They can, of course, be used freely in the herbaceous borders or in sunny open spaces in the front of the shrubbery (providing such spaces are not too full of roots). Indeed, they should always be included in such planting schemes.

If, however, it is desired to achieve the most satisfactory results, it can only be done by devoting some part of the garden mainly to their cultivation, wherein the irises are the main *motif*, and such other subjects as may be used are merely background, colour complements, or plants used to redeem the area from a sense of dullness during the period when the irises are not in flower.

Having chosen the spot, and this can be anywhere where it gets a sufficiency of sunshine, the next thing is to consider the design. The best effects are obtained by adopting lines of an informal nature. The tall June-flowering irises are intolerant of restriction

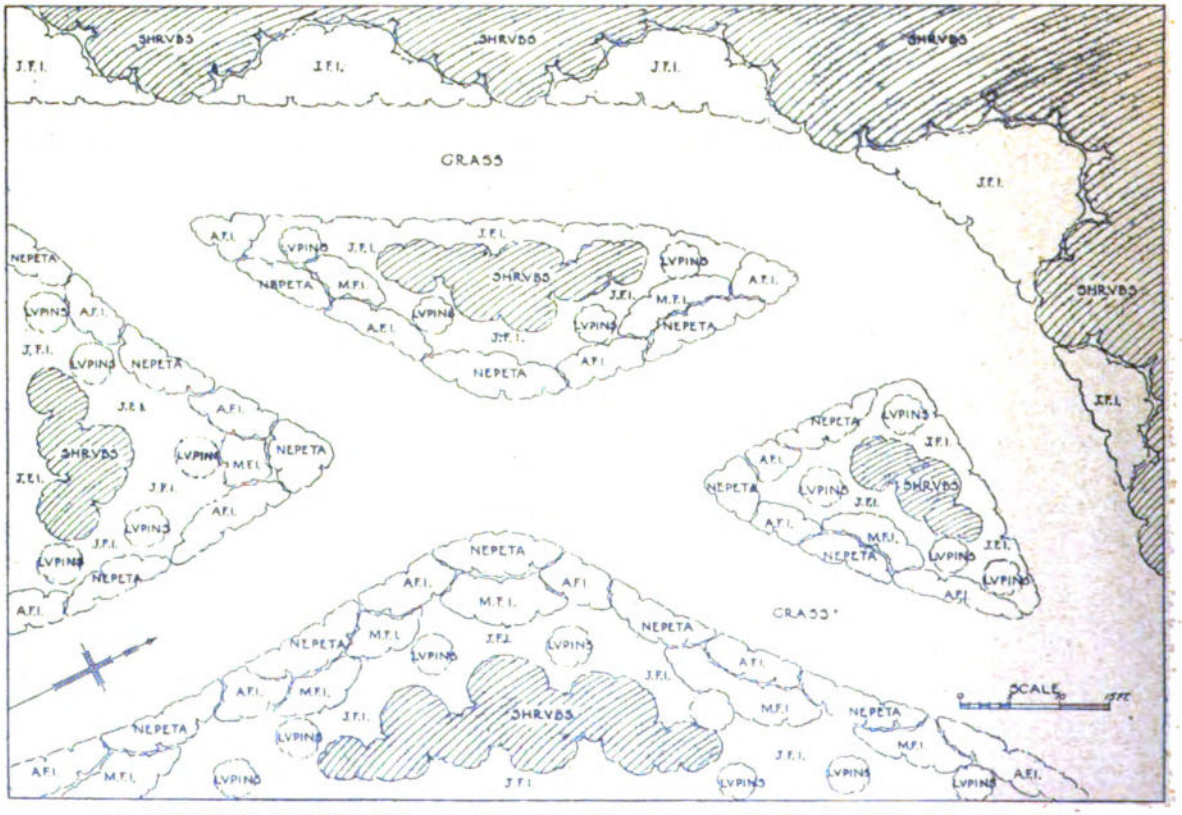
IRISES AND LUPINS MAKE A PLEASANT COMBINATION.

to rigid lines. They will spread themselves out and throw up flower spikes as and where they choose. The accompanying sketch plan indicates a treatment that can be applied to practically any site and enlarged *ad lib.* to almost any proportions. The actual development of the design consists merely of arranging the path system and thus dividing the actual planting areas into more or less irregular spaces or mounds. The word "mounds" is used intentionally, because, for both cultivation and æsthetic effect, it is best to valley out the paths, depositing the top soil so removed on the planting spaces and thus creating undulating contours over the whole areas. Incidentally, this also assists in draining the beds, and good drainage is essential to the best cultivation.

Then it will be as well to consider the chemical constituents of the soil. If it contains lime or chalk, little need be done beyond ensuring that there is a sufficiency of organic matter to produce free, healthy growth. If, however, it contains little or no lime, this should be added, either by introducing lime, chalk, superphosphate, or one of the agricultural or horticultural preparations easily obtainable, such as Limbux.

Next, consider what shrubs or plants will associate well with irises, and three examples must suffice, but there are many others equally desirable. Prunus Pissardi makes a fine background; lupinus gives wonderful colour combinations; and Nepeta Mussini (catmint) creates a cool-coloured grey-blue carpeting effect if used in bold masses between the irises and lupins.

One thing must be remembered, and it is, that, having introduced lime into the soil, such plants and shrubs that dislike it must be avoided; for instance, Erica carnea could be planted in groups as a fringe to the iris plantings, and would make an interesting splash of colour when the irises are at their very worst; but the equally attractive Erica Tetralix mollis would not tolerate such conditions. There are, however, hundreds of shrubs and plants that are indifferent to the presence of lime, which can be used effectively. Another point that must be remembered is that in the irises themselves there are certain sections that object to lime.

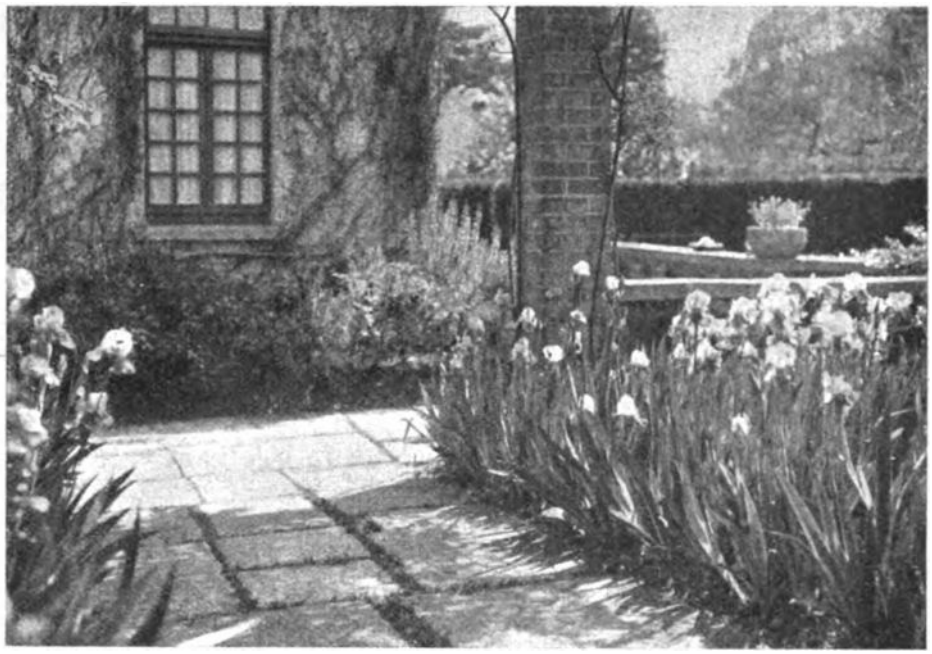


A SUGGESTED SCHEME FOR AN IRIS GARDEN WHICH CAN BE ADAPTED TO ANY SIZE.
A. F. I.—April flowering irises. M. F. I.—May flowering irises. J. F. I.—June flowering irises.

Digitized by Google

All the bearded irises are safe—April, May and June flowering. Many of the bulbous varieties will do quite well under the conditions described; but Iris Kæmpferi and a number of the fibrous-rooted species object to lime. Most nurserymen make this distinction quite clear in their catalogues.

It is impossible to review the whole genus for examples of what can be grown, so I will restrict the present suggestions to the April, May and June flowering bearded irises. All the April-flowering varieties are of dwarf habit, and should, therefore, be planted in little groups in the front of the borders: Azurea, sky blue; Excelsa, yellow; Orange Queen, with a fine orange "beard"; Formosa, violet and very fragrant, are some of the most useful. None of them grows more than about 9ins.



IRISES ARE PARTICULARLY ATTRACTIVE IF PLANTED ALONG THE PATH TO THE HOUSE.

The May-flowering or "Intermediate" varieties grow taller, from 18ins. to 2½ft., and one of the oldest, cheapest and best is the deep violet Kharput. Blue Boy, a free-flowering violet blue with a blue beard; Etta, cream; Florentina, fragrant white; Yellow Hammer, a bright amber yellow; Zwanenburg, silver grey and old gold; Kochii, dark violet; and Purple King, a rich red purple, are all worth growing. Now we come to the June-flowering varieties, the best of all irises. These can be purchased at from anything between 6d. and £20 each, but there are a few sterling varieties of moderate price that will form the nucleus of a collection and encourage further ventures when their wonderful beauty is realised. If I had room for only twelve varieties, I think the following would be my selection from those of moderate price:

Alcazar, tall and branching, standards blue, falls velvety red purple with bronze veining.

Ambassadeur, very tall, late flowering, standards reddish violet, falls a deep ruddy brown of velvety texture.

Asia, very tall, standards a curious but beautiful mixture of lavender and yellow, falls violet to purple, with a distinct reddish tint towards the edges.

Colonel Candelot, medium height red bronze standards and crimson mahogany falls.

Dream, tall, one of the best of the series usually described as pink. In reality it is a soft rose with an underlying suffusion of pale violet.

Flaming Sword, medium, a combination of deep maroon and varying shades of yellow.

Iris King, medium, old gold and velvety crimson.

Lord of June, a giant in all ways, standards pale lavender, falls bright violet blue.

Ma Mie, medium, ivory white with blue reticulations on margin.

Pallida dalmatica, tall, deep lavender, wonderful glaucous grey foliage.

Prosper Laugier, medium, standards pale brown mingled with heliotrope. Falls violet, in which is mingled a warm brown tint.

Souvenir de Mme. Gaudichau, tall, rich deep violet throughout, unique among the June-flowering irises.

The preceding collection is weak in what are known as blue-purple bicolors, but there are plenty that can be added.

GEO. DILLISTONE.

BEARDED IRISES WORTH GROWING

The bearded iris is undoubtedly an amateur's plant. Its cultural requirements are simple, while its period of flowering, wide range of colour, especially if many of the more modern varieties are grown, and its decorative effect in the garden, make it an invaluable plant for every garden, large or small. In this article a selection of varieties is given suitable for growing in all gardens, either in the north or in the south.

IRIS SOUVENIR DE MME. GAUDICHAU OF A DEEP VELVETY PURPLE COLOUR.

"IT resembles nothing but itself. There mingle in its upright and broad frills all pale shades of auburn, sepia and rose. The beard is of light gold. I have haunted the magnificent thing for a week and yet know not how fittingly to describe its beauty." Thus Mr. Eden Phillpotts, in writing of Isoline, one of Vilmorin's bearded iris creations, which any gardener can possess for the modest sum of 1s. 6d. Readers who have grown this elegant flower, with its falls and standards of fine form and substance, together with the association of fascinating art shades, will appreciate the novelist's difficulty in reproducing a pen picture that does justice to its charm. Other and newer irises may excel it in novelty of colour, texture etc., but there is no other example that is better suited for a small collection, such as is becoming popular in the amateur's garden of to-day.

I can, however, recall the time, and that not so long ago, when the amateur's experience of iris cultivation in Scotland was confined to the German, English and Spanish types. The first named pair were familiar subjects in old country or cottage gardens and were held in high esteem but it was more by good luck than good guidance that the plants managed to exist and flower regularly in early summer as they were left pretty well to look after themselves.

IRIS DOMINION, ONE OF THE BEST OF MODERN BEARDED VARIETIES.

Digitized by Google

The introduction of the Spanish iris and its rapid advance in public favour is of more recent date. The planting and lifting of the tiny bulbs involved a little more labour and attention than that usually bestowed on the German and English species. To the keen gardener with limited space at his disposal, the culture of Spanish iris has presented a perplexing problem, for the poor man's orchid flowers well into June and thus interferes with summer bedding operations. Not only is the bed required for other subjects that are to provide a succession of bloom, but the decaying foliage presents an untidy appearance that is seldom in keeping with the rest of the garden. Every year I have a bed of Spanish iris in rows of distinct colour varieties and these difficulties have been overcome by spacing the rows sufficiently wide as to enable the bed to be interplanted with chrysanthemums. By this arrangement the irises are not disturbed and the presence of the early-flowering chrysanthemums serves as a screen which hides the withered foliage until such time as it can be removed.

Within the past four or five years the bearded iris has obtained a measure of popularity among amateurs in Scotland that is expanding as the merits of the hybrids become known. Their rich and wonderful colourings reflected in the harmony or contrast of the standards and falls command unusual admiration and among their other attractive qualities, fragrance is present in a varying degree of strength.

The cultural requirements of the bearded iris are simple in the extreme. Any good garden soil meets their requirements, but if it is deficient in lime, a light dressing may be forked in preparatory to planting in August or September. Before winter sets in a mulch of rotted manure on the soil surrounding the plant is beneficial, while a covering of ashes will serve as a protection against slugs, which damage the young growth in spring. As the rhizomes have a tendency to rot when put deeply in the soil, shallow planting should be the rule. Care should therefore be taken that the junction of the leaves with the rhizome is just above the surface. Irises appreciate moisture during the period of growth, but after flowering they require dry conditions.

As regards the selection of situation, some authorities advocate a partially shaded position in preference to one fully exposed to the sun, the reason being that the flowers remain longer in bloom in the former site than in the latter. This probably represents the difference in the conditions existing in northern and southern latitudes. Judging from the experience of the past two years, such a precaution is quite unnecessary in Scotland and as the iris delights to bask in sunshine especially after the flowering season is over, a nice sunny place should be chosen.

New irises of distinctive colours are introduced annually and the number of varieties in commerce offer a choice to suit every taste, position and purse. The following list, arranged in accordance with the classification scheme of the Royal Horticultural Society, is prepared in the interests of small growers who can form their own collection by choosing varieties that range in price from 1s. to 2s. 6d. each.

Class I: White.—May-flowering, Ingeborg, 2ft. June-flowering, La Niege, 2ft.

Class II: White, feathered with purple.—Jean d'Arc, 2ft. Dimity, 3ft.

Class III: Standards, white; Falls, purple.—Tristram, 2ft. Richard II, 1½ft.

Class IV: Purple bicolors.—Oriflame, 2½ft. Alcazar, 3ft., or Lord of June, 3½ft.

Class V: Purple selfs.—Ed. Michel, 3½ft. Pallida dalmatica, 3½ft.

Class VI: Standards of shot shades.—Isoline, 3ft. Iris King, 2ft., or Jacquisiana, 2½ft.

Class VII: Standards, yellow; Falls, blue, red or purple.—Romany, 2ft. Dusky Maid, 2½ft.

Class VIII: Yellow selfs.—Eldorado, 2½ft. Sunshine, 2½ft.

To the more ambitious grower who desires a more up-to-date collection of moderate priced varieties, the following will be found representative of the best:

Ambassadeur (Vilmorin).—Standards, reddish violet, suffused bronze; falls, deep violet crimson; scented, 2ft.

Asia (Yeld).—Standards, silvery lavender, suffused yellow at base; falls, violet purple, paler at edge; bright yellow beard; scented, 4½ft.

Ballerine.—A new heliotrope self, flowers waved at margin and sweetly scented.

Crusader (Foster).—Standards, lavender blue; falls, violet blue; orange beard; strongly perfumed, 3½ft.

Corrida (Millet).—Violet blue self, the falls being just a shade deeper, scented, 3ft.

Flaming Sword.—Standards, deep yellow; falls, purple, edged gold; very effective, 3ft.

Souvenir de Mme. Gaudichau (Millet).—Deep velvety purple bicolor, one of the best of modern introductions, scented, 3½ft.

Magnifica (Vilmorin).—Standards, light violet blue; falls, dark reddish violet, striped brown at base; scented, 3ft.

Shalimar (Trojana seedling).—Standards, almost a true blue; falls, violet; shading lighter at the edge; scented, 3ft.

Lent A. Williamson (Williamson).—Standards, lavender violet; falls, velvety purple, edged violet. One of the best varieties raised in America, 3ft.

To complete a dozen, I would recommend Dominion and Aphrodite to those amateurs who do not require to consider cost. The former is admittedly one of the most beautiful irises in cultivation, while the latter is regarded as the best of the so-called "pink" irises and each of these are now purchasable at less than a pound. J. Y.

How to Grow Fine Irises

In this article full details are given as to how to attain success in the growing of irises. All the necessary information as regards culture, time of planting, and choice of situation is divided up according to the different groups which go to make up this attractive genus of garden plants.

THIS beautiful genus has always been deservedly popular, including, as it does, so many beautiful species and varieties. Many of them are so easily cultivated that there are few, if any, gardens in which they may not be successfully grown.

The Flag or German Irises.

In recent years the raising of many new and attractive varieties in the tall bearded section, generally known as German or flag irises, has resulted in almost a craze for the acquisition and cultivation of these beautiful plants. The common early purple flag iris, I. germanica, as well as many of the strong-growing varieties in the June-flowering section, will grow almost anywhere except in shade and in very poor soil, and on this account are ideal for town gardens, I. germanica specially thriving in very poor soil in hot, dry positions.

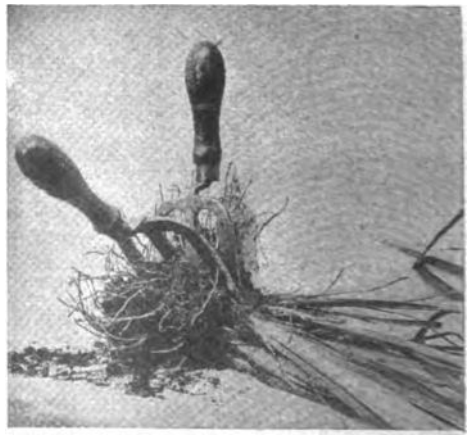
A clump of the Siberian iris now ready for division immediately after flowering is over.

Cultivation.

We will now consider briefly the cultural requirements of this large and popular class of bearded iris. Although they will thrive in very poor soil, a good medium loam may be considered ideal for them. Too heavy, cold and wet soils are unsuitable. In such situations it would be wise to grow them on raised beds or banks, as warmth and free drainage are very essential for ripening the rhizomes. In preparing the beds or borders avoid the use of fresh manure. Well decayed farmyard manure should be dug in deeply so that it does not come in contact with the roots of newly planted irises. In this connection it is well to note that fresh loam is of more importance than manure; in fact, where large collections are grown it is necessary to give the plants fresh soil or move them on to new ground occasionally if attacks of disease are to be prevented. Lime is essential to this section, and in lime-free soils a good dusting should be forked into the surface before planting. If it can be obtained, lime rubble is excellent for this purpose, and on heavy soils may be used with advantage to keep the soil open and porous. Basic slag applied at the rate of 6 oz. to 8 oz. per square yard may be used instead of lime. Although best applied during the autumn, it may be used at any time when the beds are being prepared. Bone meal or steamed bone flour may also be used at the rate of 6 oz. to 8 oz. per square yard.

Time to Plant.

They are very accommodating plants, and may be successfully planted any time



When dividing large clumps it is best to do so with handforks, discarding the central portions.

Digitized by Google

during the autumn or spring, and even during the winter when the conditions are favourable. There is, however, no doubt that the best time is from July to September or, indeed, as soon as possible after they have finished flowering. This gives them plenty of time to form new roots and get established before winter, with the result that there should be little loss of flowering the following season. Shallow planting is very important, the rhizomes being covered with no more soil than what will hold them in position, as naturally they grow on the surface of the soil, which indicates the importance of growing them in open positions well exposed to the sun. When dividing large clumps for replanting, the strongest portions should be selected, discarding the weaker portions from the centre of the clump. Old and useless portions of the rhizome should at the same time be cut away. If the planting is done during July, it may be necessary to keep them watered if a dry spell should intervene.

Grouping.

For practical purposes we shall consider the flag irises in three groups, roughly divided by their flowering period. In the first or April flowering group we have the Iris pumila and Chamæiris varieties as represented by such sorts as alba, atroviolacea, azurea, Excelsa, Orange Queen and Snow Cap. They are all dwarf growing and are well suited for the rock garden, also for making edgings to beds and borders. The second group of intermediate bearded irises flower during May, and are derived mainly from crosses between the dwarf I. pumila varieties and the later flowering germanica varieties, and includes such fine varieties as Blue Boy, Cretan, Ingeborg, Kharput, Margaret and Dolphine. Here we must include the sweet-scented I. florentina, the source of orris-root. The third, or June-flowering, group is the largest and most important from the standpoint of the cultivator, and in recent years many fine new varieties have been added to this group, which includes the pallidas, variegata, squalens, amœna, neglecta, plicata, junonia and trojana varieties. We can, however, only consider them collectively and out of a bewildering list indicate a few of the outstanding varieties that are reasonable in price, *viz.*, Albert Victor, Alcazar, Asia, Black Prince (very late), Camelot, Lord of June, Lady Foster, Gold-crest, Dimity, Isoline, Mrs. Neubronner and Souvenir de Mme. Gaudichau. Intending planters should, however, see them in flower and make their own selection.

Iris sibirica and its varieties also flower during June, and although they can be successfully grown in beds and borders like the larger flag iris, they are, however, specially suited for planting in masses near the waterside, as they succeed well in moist situations. Their successful cultivation presents no difficulty. They may be replanted after flowering during autumn and spring. There are several fine varieties, such as Perry's Blue, George Wallace, Snow Queen, Ariel, Maxima and Baxteri.

Iris Kæmpferi is another group of moisture-loving irises which love a warm, sunny position by the margin of ponds and streams, although they can be grown perfectly in beds or borders where they can be occasionally flooded during growing and flowering season. Planted in such situations one must remember that they must be high and dry during the winter. They enjoy a rich root-run and, like all the groups already dealt with, are best replanted after they have finished flowering. Other irises suitable for planting by the waterside in full sun are I. aurea, Delavayi, Monnieri Monspur, ochroleuca and our native Pseudacorus. With the exception of the last they are all worth growing in an ordinary well cultivated border.

Iris stylosa and its varieties flower during the winter and spring, and on account of their sweet scent and freedom of flowering should find a place in every garden where they can be planted in poor soil at the foot of a hot, sunny wall. This iris is best replanted during March after it has finished flowering. It may also be successfully planted during September.

THE WINTER FLOWERING IRIS, I. STYLOSA, FLOURISHES AT THE FOOT OF A SUNNY WALL.
This species is best planted in March or early September.

IRIS TINGITANA, ONE OF THE MOST BEAUTIFUL OF ALL OUR BULBOUS IRISES.
The bulbous or tuberous rooted varieties should be planted in late September or October.

Bulbous and Tuberous-rooted Irises.

Beautiful and useful as the so-called flag irises are, it is in the section under consideration that the most exquisite gems of a wholly beautiful genus are to be found. They are ideal for growing in pots and pans for the furnishing of the alpine or unheated greenhouse. Most of them are also suited for choice situations in the rock garden, or they may be grown to perfection in narrow borders at the foot of warm walls. Their cultural requirements are quite simple, the essentials being a light to medium, warm, well drained soil. As the small, choice species and varieties are usually grown in small quantities, it is easy to prepare special sites for them if the original soil is at all unsuitable. They should all be planted during the autumn as soon as they can be procured. Generally speaking, October is the best month for planting. This section includes such well known and beautiful species as I. alata, Danfordiæ, histrioides, orchioides, persica, reticulata, tingitana and Vartani.

The bulbous section includes what one might term everybody's irises, *viz.*, the well known and popular Spanish and English irises, which are unrivalled in their many beautiful varieties for a supply of cut flowers and are so reasonable in price that they can be used in quantity for this purpose or for furnishing beds and borders in the garden. There is also a new section known as Dutch irises. They resemble the Spanish varieties, but bloom at least a fortnight in advance of them. They all enjoy a warm, well drained medium loam, and should be planted during October.

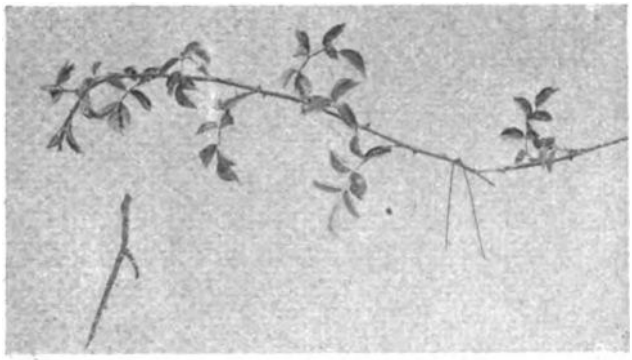
THE BUSY MAN'S PAGE

Layering Roses.

ROSES can readily be propagated by layering, which may be carried out at any suitable time now. Select a well ripened growth coming from near the base of the bush or so placed that it can readily be bent down to the ground. At the spot where it touches the soil make an incision to one-half of the thickness of the stem in



A ROSE SHOOT PREPARED FOR LAYERING.

a slanting direction up towards the tip of the shoot and always through a leaf-joint, the leaf having been previously removed. Scoop out a shallow depression in the soil underneath where this wound has been made, gently push the shoot into this, bend the tip upwards a little so as to leave the incision gaping, then pin firmly in position, with a bent wire or a V-shaped twig or with a proper layering pin. Cover up with soil in such a way that a depth of some 3ins. is placed over the incision, press firm and see that all is secure. In many gardens no further attention is required, but should the soil be a porous one, then daily waterings are necessary to keep the soil moist and to encourage rooting. In very sandy loams some leaf-mould or fine lawn mowings may be laid on top for a similar purpose. By spring roots will have formed; the new plant may then be severed from the parent bush and planted elsewhere.

Plants During Holidays.

IF holidays do not extend over a prolonged period, readers may easily provide for their pot plants without anticipating any harm or even deterioration during the time when they are away. First of all, let us state that the plants must not be kept in darkened rooms, nor must the pots stand in water; water in the saucer, too, is to be avoided, as it tends to sour the lower soil in the pot and destroy the roots of the plants. Let the plants stand in full light, but not in direct sunlight. To keep the soil moist, pack the pots round with wetted newspapers in a box, or plunge them in a pail containing wet sawdust, soil, peat or fibre. Aspidistras, palms, araucarias and many other plants will be better in the open for the period; indeed, they come in, after a spell outside, refreshed and vigorous. Scoop out a hole under a tree or in semi-shade beside a bush, drop in a handful of ashes, place the pot in this, fill soil all round it, water well and leave it alone for a month or two. Plunged in ashes in semi-shade they are almost equally well provided for. Window-boxes, tubs and plants in boxes should be taken to a shaded corner, well watered and then packed round with leaves, ashes, wet bags, fibre ora nything else which will keep the soil inside the receptacle cool and moist. It is impossible, however, to provide in any effective way for a greenhouse collection, and readers must be obliged to a neighbour or to a jobbing gardener—who, please note, should be given explicit directions.

Rose Leaf Diseases.

BLACK spot is a parasitic fungus appearing on the foliage as purple blotches which rapidly darken and become black. Leaf scorch differs in appearance, the pale yellow spots gradually darkening and having a purple margin. Blotch is a brown infestation which also attacks the soft new shoots and buds. Unfortunately, it is not possible to do very much in the way of eradication; spraying with liver of sulphur, 1 oz. in 3 gallons of water, or with any fungicide which does not discolour the leaves or leave a white deposit, like Bordeaux mixture, should be practised, however, to prevent the diseases from spreading and to keep them somewhat in hand. Mildew, on the other hand, can be cleared away by any of these fungicides, and, as it is much more destructive and crippling to the bushes than is generally supposed, we urge every grower to treat it with respect and eradicate it. Rust is seldom harmful to any extent on garden roses. In all cases rake up and burn or bury deeply the fallen foliage in autumn, a most essential point in the case of the spot, blotch, scorch and rust, and give the soil a dressing of slag and potash salts, equal parts of each, applied as soon as mixed, at the rate of ½lb. per bush. Spraying with formalin in winter and spring is also advisable where spot, blotch and scorch are known.

Watering Hints.

STRICTLY speaking, in every garden there should be the means for the storage of rain-water. Where no such facilities exist or the supply of rain-water is exhausted, arrange to have a tub or a tank in an open position and fill this from the main. The action of the sun and air on the water will have a softening effect, and supplies drawn from the tub will be almost as good as rain-water. The receptacle can be easily filled by means of the garden hose.

Of course, much may be done by the use of the hoe to help plants to withstand a dry spell; but, if the rainless period is prolonged, watering will have to start. It is most important that this should be done thoroughly on well loosened soil. The idea is to apply the water so that it will penetrate to some depth; if the moisture only gets down a few inches the fine roots of the plants are encouraged to come too near to the surface instead of penetrating into the soil as should be the case.

On the whole, the evening is the best time in which to water, and, during hot weather, many plants benefit greatly from being sprayed all over with cool water. Overhead watering during the day is not so harmful as is commonly supposed. In this connection it may be pointed out that days in which showers alternate with bright, hot sunshine are often experienced without harm to the plants. Probably where scorching occurs after overhead watering the trouble is due to the use of cold, hard water. If soft water, taken from a tub fully exposed to the sun, is employed, there is very little fear of damage to foliage.

Plants that grow against walls or fences, or close to large shrubs and trees, will have special need of moisture in the summer. These never get the same amount of natural moisture as the subjects growing in more open positions. Wall fruit trees often suffer very much indeed in this way, and fruit dropping and a generally poor development is the result. The dryness may be prevented by a loosening of the surface soil, followed by a good soaking of water as required. Follow with a mulch of leaf-litter, grass cuttings or any similar material.

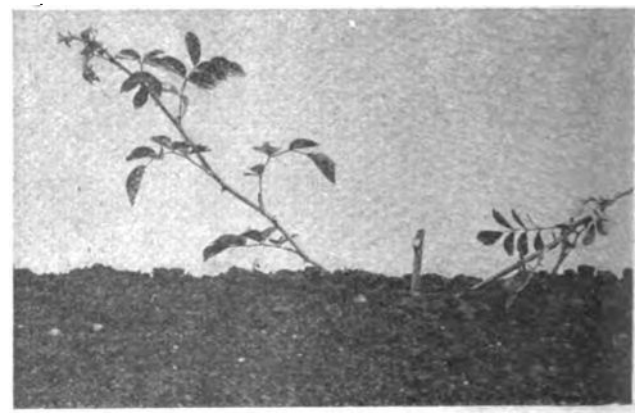
A long dry spell often affects shrubs (particularly rhododendrons) very badly indeed. It is a very excellent plan to dig a shallow trench all round the specimen which can be filled right up with water. Roses will also be helped by a similar arrangement.

Ants on a Lawn.

A COLONY of ants on a lawn will often make a very unsightly patch, and it is difficult to deal with the pest without damaging the grass. A very excellent plan by means of which all the ants may be trapped is carried out in the following manner: Get a large empty flower-pot in which the hole has been stopped, and then invert this over the opening that the ants have made. Ants will always build their nests in the driest possible positions and they are sure to go up into the pot. The removal is hastened if, after the placing of the pot on the ground, the outside is well soaked with water on a few occasions. When on looking through the hole in the pot, it is seen that the interior contains the nest, push a spade under the pot and drop the whole thing into a tub of water.

Gathering Roses.

THE condition of the blooms when taken from the plants largely determines their lasting qualities afterwards. Gather the buds, then, just as they are on the point of opening.



AFTER LAYERING: THE SHOOT PEGGED DOWN IN THE SOIL.

Early morning is, perhaps, the best time for cutting the buds. The next best time is late evening. Always secure a good length of stem; three or four buds at the base will produce sufficient shoots for a plentiful crop of blossoms in the autumn. Besides, length of stem has a great deal to do with the arrangement of the blooms. A word as to the actual cutting: a keen-edged knife is undoubtedly the best implement to use, as it makes a perfectly smooth, clean cut.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Training Gooseberries.

I WAS at Wisley last week, and was greatly impressed with the care that had been bestowed on the training of bush gooseberries. The trees were about ten years old. From a central stem branches had been trained to radiate, and kept pruned so that there was plenty of room between the branches to gather the fruit. This desired condition has been gained by thinning out the shoots and disbudding during the summer. When once a tree is developed into the right shape, all the treatment required is to thin out the young shoots where these are too crowded and to shorten the side shoots four "eyes" to form fruit spurs, and to regulate the leaders to retain the symmetry. The illustration shows a well grown gooseberry trained as a five-stemmed cordon. Any number of shoots can be trained in this way from one plant, although seven is generally the maximum, and frequently only two leaders are allowed to grow from one plant. This method of training bush fruits, such as gooseberries, red and white currants, is especially commendable in the small garden.

Late Seed Sowing.

IN some parts of the country brought has been a severe set-back to the vegetable crops. Peas, green crops and salads have been the worst sufferers.

It is not generally known that excellent vegetable crops can be grown from seeds sown in July. The secret lies in sowing the seeds where the crop is to stand; in other words, avoid transplanting. Sow thinly, and single out the plants at the earliest possible moment. Seeds germinate rapidly in summer because the soil, which has for the past few weeks been storing up the sun heat, is warm. Suppose a row of peas has failed. There is no reason why another sowing should not be made in the same trench.

It is essential to sow early varieties, such as Little Marvel. Pods should be ready for gathering in seven or eight weeks. Lettuces, both of the cabbage and cos varieties, can be grown to maturity before the winter comes on. They, too, must not be transplanted, or they will not heart until spring. Round or summer spinach is the best kind to sow for a quick crop of this vegetable, and this can follow the early potatoes. If the land was manured in spring no further manuring need be done.

The Problem of Staking Tall Perennials.

UNFORTUNATELY many of our most beautiful garden flowers require support of some kind. Delphiniums are a case in point. They grow quite 6ft. tall, and bear heavy spikes of blossom. When these are weighted with rain, and blown by the wind, it is not surprising that they fall over unless given some support. The most artistic method of giving this is by means of inch square wooden stakes, painted green. Each clump will need three stakes placed trianglewise round it. Fairly stout string is essential to hold the weight. In placing the stakes, leave one stem loose by each, so that it can afterwards be tied to the front of the stake. When the work is completed, each stake should be hidden, and after a few weeks of growth it should look as though no staking has been done.

The Gardener's Friends and Foes

Big Bud on Black Currants.

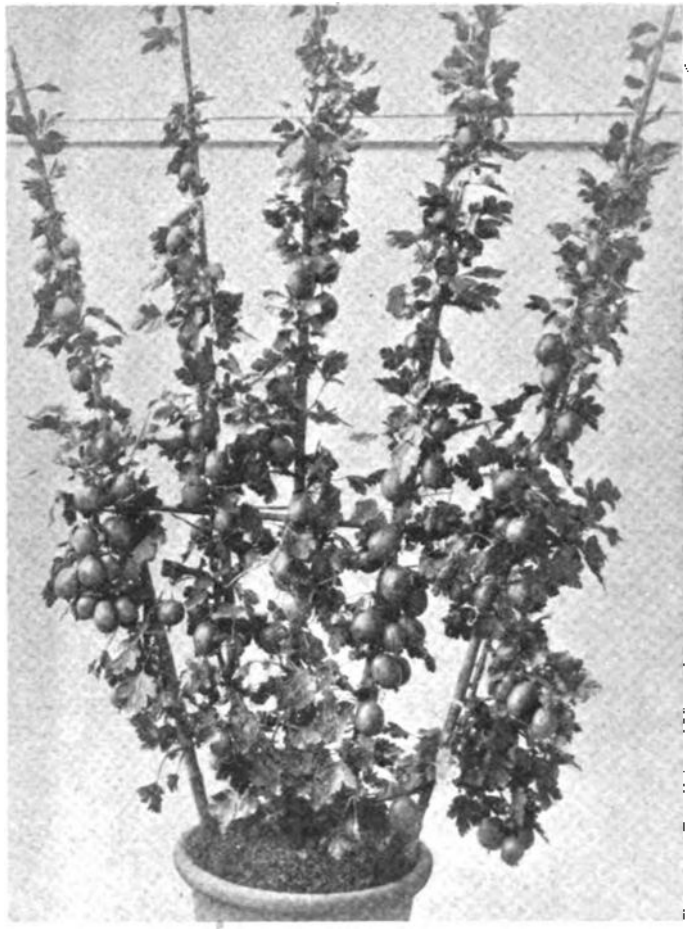
WE can now easily detect the presence of big bud on black currants. If, instead of shoots, the buds form round knobs on the stems, it can be assumed that the big bud mite is present. Cut one open, and the mites will be seen as tiny white specks. This is about the only serious pest of black currant. The remedy is to burn all badly affected bushes, and hand-pick the swollen buds and burn them. This is but a temporary measure, and in districts where the mite is common replanting with a variety such as Seabrooke's Black, which is almost immune, is advisable. Young wood should be encouraged and old wood cut away after fruiting.

Cabbage Butterflies.

The whitish butterflies over the cabbage patches in early summer are themselves harmless enough, but as they lay eggs which hatch out into caterpillars we must make war on the butterflies. Invert bottles on sticks so that the bottoms are above the leaves of the plants. On each put a few pieces of broken brimstone. This should keep the butterflies away. Should caterpillars appear, spray with a solution of common salt in water—as the cabbages are natives of the seaside they do not mind salt.

Garden Friends.

Many insects are our friends. Spiders destroy flies, moths and swarms of aphides. Glow-worms destroy snails. Hover flies and lace-wing flies and ladybirds feed on aphides. Some ground beetles (generally those which are very active on their legs) live on insects and snails. And in the animal world, birds (especially the song birds), frogs and toads are also our comrades in the war on troublesome insects.



A WELL GROWN GOOSEBERRY BUSH TRAINED AS A FIVE STEMMED CORDON.
Several shoots can be trained in this way from one plant.

Summer Pruning.

"SPARE the knife and spoil the tree," might well be the fruit-growers' motto. Hardy fruit trees and bushes always make an abundance of growth during the summer months, even while the fruit is still on the trees. This growth is essential, as upon it depends next year's crop.

Usually, however, a plant will make more growth than is needed, and it is necessary to summer prune in order to reduce the formation of sappy growth, to encourage the formation of fruit spurs, and to allow a free access of sun and air to the centre of the tree.

Apples, pears and plums should have in-growing shoots cut away, as well as any dead or diseased wood. Take away all weakly side shoots and shorten strong ones to about four leaves, allowing the leading branches to remain until autumn. Note trees that are growing too strongly and root prune them in autumn.

A few varieties of apples (Lady Sudeley, Irish Peach, Golden Noble, Waltham Abbey and Devonshire Quarrenden), and also the Jargonelle pears, fruit chiefly on the ends of the shoots, and their summer pruning should be limited to thinning out weak or overcrowded shoots. Cherries with the exception of the Morello bear their fruit on spurs, and the less the wood of one year's growth and upwards is pruned the better, for fear of setting up gummosis—a bleeding of gum from the wound, which causes much injury. The Morello cherry (which is one of the best fruits for a north wall), bears its fruits on the previous year's growth, consequently the young shoots should be retained. After the the fruit has been gathered, cut out shoots that have borne fruit, and if the tree is trained on a wall or fence, tie in the growing shoots. If grown as a bush, thin the side shoots to prevent crowding.

Treatment of Loganberries.—A phenomenal grower, the loganberry makes huge shoots before its fruits are ripe. As soon as the fruit is cleared the old wood should be cut away, and the young shoots trained in their stead. In the meantime, a temporary tie, either to a stake or the fence, should be made, to prevent the tender shoot from being broken by high winds or other agencies. Also, cut away the old canes of raspberries as soon as the fruit has been gathered.

Digitized by Google

WORK IN THE FLOWER GARDEN

Seed Pods on Rhododendrons.

NOW that the bulk of the flowers are over, time should be found to remove the seed vessels, as, if allowed to remain, next year's crop of blossoms will be much reduced. The best and earliest varieties should be dealt with first, but none should be overlooked if they can possibly be attended to. Generally, nice young buds are to be found in process of development at the base of the seed pods, and a certain amount of care is needed when picking off the latter, or injury to these buds will result. Future displays must be considered.—J. C.

Antirrhinums.

Mid-season Duties.

ANTIRRHINUMS are becoming increasingly popular every year, and will grow well in most districts and soils, and anything which can be done to help their duration of flowering should not be omitted. During the next few weeks much assistance can be given. If the weather be dry and hot, it will be an advantage to hand-fork about them, but not too near the roots, and spread over the surface a mulch, either of old rotted manure or leaves. This will conserve a deal of moisture and save much labour of watering. As with sweet peas and violas, the secret of a continuity of blossoms lies in keeping spent flower stalks cut. With antirrhinums, the presence of seed pods should be a danger signal that ought to be observed. Every week, at least once, if not twice, they should be gone over, and all decaying flowers cut away. In the case of the tallest, it is wisest to give each a stake, tying them to prevent their being dashed by heavy rain or wind. At the time of their flowering, one may administer a little fertiliser every week, in the shape of bone-meal, forking it in. Watering is best done at night. The idea should be to prolong the present display for as long as possible, and therefore seed formation should be prevented. If one desires to perpetuate some particularly good sorts, this can be done by taking cuttings in late autumn and planting in a cold frame; but there is nothing gained in a small garden by allowing plants to go to seed and stopping the development of other spikes.—W. F.

M. VIOLACEA WITH VIOLET BLOOMS.

A Fine Summer-Flowering Shrub.

Fabiana imbricata.

AMONG flowering shrubs during the month of June, the evergreen heath, Fabiana imbricata, is most conspicuous, and here, in

A HANDSOME SUMMER-FLOWERING SHRUB FOR A POSITION ON THE LAWN.

the Chepstow area, it has proved hardy in the open border. In some districts it is reputed to be somewhat tender, but there are many readers of THE GARDEN who would succeed with it in the open, or as a wall plant with a south or south-west aspect. Fabiana imbricata attains a height of several feet and is somewhat spreading, and when in blossom it is very effective. The large, waxy white, tubular flowers are thickly set around every shoot, giving the effect of a long raceme of bloom, and at this stage it is a most beautiful shrub. It enjoys a light soil to which a little peat and sand have been added. Small plants flower freely, and as a pot subject for the cool greenhouse it has much to commend it. This charming shrub is readily increased by cuttings, and young shoots soon form roots during August and September if placed in a cold frame or hand-light. If desired, plants can be kept small by fairly hard pruning and pinching immediately after flowering.—B.

Two Blue Poppies for a Bed or Rockery.

BURMA is not generally regarded as the home of alpine plants, but in the extreme north, where the Irrawaddy rises, are snowy mountains covered with flowers, such as primula, gentiana and meconopsis.

Among the latter are two fine species, a form of M. Baileyi, and a new species called M. violacea. The first to flower is M. Baileyi, a sky blue meadow poppy, which at low altitudes (10,000ft. to 11,000ft.), flowers early in June, but which may be found in fine bloom as late as August at 12,000ft. and over. The steep alpine meadows, where the soil is a rich loam, overlying gravel, are blue with its floppy balloons at the end of June. Ample moisture, good drainage and a fairly rich soil of leaf-mould and sand are required. Unlike typical M. Baileyi, this variety—which comes nearer M. betonicifolia—dislikes shade and grows right out in the open. But it must be remembered that in its native country it gets almost no direct sunshine, and that unless it gets plenty of water, an English summer sun will burn it. So long as the roots are kept moist, it will suffer no ill effects, however. It is quite hardy and perennial. A full grown specimen stands 3ft. to 4ft. high and it will no doubt come as easily from seed as M. Baileyi itself.

M. violacea flowers later. It is not found below 11,000ft. and scarcely opens its topmost flower before the end of June. When the snow is melting you will find big rosettes of this plant, which have passed through the winter preparing for the season. The leaves are very big, almost pinnate (actually very deeply divided) and covered with golden yellow hairs. Soon the tall flowering stem begins to rise from the centre and it rapidly shoots up, bearing small leaves from the axil of each of which a silken flower hangs out like a flag. The flowers are of a beautiful shimmering violet, with the texture of Japanese silk, and in the centre of each is a sheaf of golden stamens. The leafy column of buds and nodding flowers is very effective.

The plants grow singly, two or three together sometimes, but never massed, on steep alpine meadow slopes, where the rough stony soil is very wet, but well drained. If you dig up a plant, you find that the carrot-like root goes down 3ft. or 4ft. into the loose, slipping earth. A light soil composed of at least half sand is recommended for this plant, and it must have sufficient depth for the root to descend, and sharp drainage. It is biennial, but will probably seed itself. Throughout the summer M. violacea continues to grow, unfurling flower after flower and in spite of their apparent flimsiness, they last long enough to accumulate six or eight in bloom at the same time. Eventually the plant attains a stature of about 6ft. Its nearest ally is probably the yellow-flowered M. robusta.—F. KINGDON WARD.

A BEAUTIFUL FORM OF M. BAILEYI WITH NODDING BLUE FLOWERS.

A Good Wall Shrub.

COROKIA COTONEASTER is a remarkable and interesting shrub from New Zealand, from whence it was introduced about 1875. For a number of years it was considered rather tender, but time has proved it to be fairly hardy, and even in less favoured parts of the country it would probably succeed as a wall plant without any further protection. As a wall shrub it has much to commend it, and, moreover, in such a position its quaint system of contorted branches, with numerous similar twigs, could be readily examined, and these never fail to arouse the interest of all plant lovers. The tiny evergreen leaves are spoon-shaped, and the leaf stalks, which are flattened, are also an additional attraction. We have examples planted against a south wall and in the open ground; both flower freely each May, but so far the plants have not set any fruits. These it is stated are small, red, and oblong in shape.

The blooms are yellow, star-shaped, and about ½in. across, and a specimen when in full flower is quite a decorative shrub. C. Cotoneaster is rather slow in growth, and specimens 4ft. to 6ft. high are usually seen, although it is said to attain a height of 8ft. This plant may be increased by cuttings in July and August.—B.

An Excellent Trellis Plant.

POLYGONUM BALDSCHUANICUM is one of the best possible climbers for covering trellis, etc., and of recent years it has appeared in many gardens. The vigorous growth shown by this polygonum is often astonishing when a specimen has become really established. Those who have newly planted examples should note that during the first year of growth the climber benefits enormously if the ground about the roots is well soaked with water in dry weather. In succeeding years no attention of this kind is ever likely to be needed. From a foliage point of view, P. baldschuanicum is attractive, but when its masses of white flowers are produced the effect is really very fine indeed. As a rule, the flowers begin to appear about midsummer, but the season of blossom may be much prolonged if a little summer pruning is carried out. During the growing season the climber develops large numbers of new shoots, and as soon as the plant is well in flower some of these shoots should be cut back to about half their length. The pruning might be done at intervals of about a fortnight. It will be found that the stopped shoots break into flower at a later date and a good display of blooms is thus maintained until well into the autumn.—L. B.

Work in the Rose Garden.

ROSE beds should be kept free from weeds, and the hoe should be kept working the surface soil, preventing it from becoming caked. This helps to prevent excessive loss of water by evaporation. A top-dressing of partially decayed farmyard manure will greatly benefit the trees and will keep the soil round the roots cool and moist. During the blossoming period the roses should be given a good watering once or twice a week with dilute liquid manure. The liquid manure may be made by placing a bag of sheep manure into a tub of water, and after this has soaked for a few days, using a quarter of a can of this solution, filling up the can with water.

Ramblers.—The new growths that are springing up from the base of the plant should be tied in and any weak ones or those in excess of the number required for next season's flowering should be cut out.

Disbudding.—For choice flowers disbudding should be practised, leaving only one bud per shoot. This should be done as soon as the lateral buds are large enough to be seen, when they can easily be removed by pinching out with the finger and thumb or breaking off.

Pests and Diseases.—Green Fly: This insect pest of the rose often spoils the shoots and gets on the young growths and the leaves. A good spraying with soft soap and nicotine is a sure remedy for aphis; while pure water, if applied with sufficient force, will control them to a large extent.

Mildew.—Mildew on roses can be combatted by spraying with lime sulphur, summer strength 1 in 60, or by dusting with flowers of sulphur. Certain varieties are particularly susceptible to mildew, *e.g.*, Lady Waterloo, and should be sprayed as soon as the disease occurs.

Achilleas for Every Rockery.

THE achilleas are worthy subjects for any rock garden, and particularly are they of interest to the enthusiast who wants something which is showy and, furthermore, not too difficult of cultivation. Not to the flowers alone is the attraction of achilleas confined, for those which have the silvery leaves are very ornamental at all times, and there are also sorts having pleasingly scented leaves. As a whole, these plants require a sunny position with light porous soil to which, if you wish, you may add a little lime, though this does not seem absolutely essential. Following are a few which any enthusiast may try with every hope of success:

Achillea argentea, which is usually one of the first to flower, is a silvery-leafed plant of neat habit, producing white flowers arranged on a 5in. or 6in. high umbel. Another with silvery leaves and white flowers which ought to be included in any collection is A. Clavennæ.

A. Kellereri is not so generally known, but is a very deserving plant. Its bluish grey leaves are about 4ins. long and finely divided. The flowers are white, and the whole impression is that the plant is very distinct and a tidy grower.

A. Letisii, a comparative newcomer, is to be particularly recommended, in that its sulphur yellow flowers provide a welcome change of colour. Other points in its favour are that it is easy of cultivation, is not exacting in its requirements and, what is of great importance, has a long flowering season.

A. Portæ commences to produce its white flowers early in the season, and its abundant supply of silvery grey leaves provides a pleasing effect at all times.

Perhaps one of the daintiest of the achilleas is *A. rupestris*. This has white flowers and silvery leaves which are slightly scented.

A. tomentosa, with its green ferny leaves, is also to be considered. Though not such a good winter furnisher as some of the foregoing, it is by no means to be despised, and its head of yellow flowers seen in mass are very effective.

A. Wilczekii is a plant differing from most of its tribe in having broad leaves which are slightly downy and saw-edged. It is a free-grower, producing 9in. high umbels of white flowers.

Those mentioned are but a few of a fairly long list of good achilleas, but if the writer has succeeded in arousing any measure of interest in the reader then he has achieved his purpose.—W. H.

ACHILLEA KELLERERI IS NEAT AND COMPACT IN GROWTH.

An Easily Grown Veronica.

UNFORTUNATELY, Veronica gentianoides does not appear to be cultivated to nearly so great an extent as its undoubted merits deserve. It is a most excellent subject either for the rockery or herbaceous border, although it is as a plant for inclusion in spring bedding schemes that this veronica excels. As a groundwork for a bed of tall Darwin or May-flowering tulips it is particularly striking. The racemes of greyish-lavender flowers are from 6ins. to 1ft. in height, and are produced with great freedom.

V. gentianoides is of very easy culture, and it will succeed quite well in a sunny open position in any ordinary garden soil. It is readily increased by means of division immediately after the flowering period.

The Staking of Dahlias.

AS the side shoots develop, secure them to the stake by a piece of raffia looped around the branch and then to the stake. As the plants grow, place three or four other stakes so that their bases form a triangle or square round the central stake, and loop twine around these to keep the plants together.

The plants will make numerous shoots and some of the weaker of these should be removed to obtain best development. Seven to eight shoots may be left. When the plants are blooming freely occasional watering with diluted liquid manure water will be found beneficial. The beds may be top-dressed with partially decayed stable manure, and this will keep the roots cool and act as a fertiliser.

Empire Stone Co.

ORNAMENTS FOR THE GARDEN

Empire Stone Co.

To even the smallest garden an ornament, whether it be a vase, a sundial or a bird's-bath if well placed with due regard to its surroundings and the design of the garden, will add beauty and interest.

THERE are few people who will deny the necessity of ornaments if a garden is going to have that finish which emphasises the owner's love of it. Beyond remarking that restraint and appropriateness should be cardinal principles in the decking of a garden, one cannot generalise on this subject without becoming merely verbose. It is better, therefore, to pass forthwith from the general to the particular and to direct attention to certain matters that should especially be borne in mind. Consider the sundial. This is a feature that can be introduced with good effect in any garden. It looks best when given a special position—at the end of a vista, or at the junction of two intersecting paths, or in the centre of a lawn or garden enclosure. Elsewhere it is apt to look lost and inappropriate. For the pedestal, most people will incline to stone for the material, and the baluster shape has much to commend it. A brickwork pedestal has the merit that it may be specially designed to suit individual taste, and brickmakers have moulded bricks which assist to this end. For a birds'-bath it is well to choose some place in the garden where this feature not only has some definite value as ornament, but also one where it can be seen from the windows of the house. To watch birds taking their bath is a constant delight. Another position that recommends itself is one where it is in view from a garden seat, and for this position a birds'-bath of basin form, set in the grass, is well suited. The pedestal type has much the same decorative effect as the sundial, and, accordingly, the positions suitable for it are much the same as those first indicated.

A GARDEN ORNAMENT HAPPILY PLACED. "Sussex" Garden Ornaments Co.
This bird's-bath is made of reinforced imperishable stone.

Then there are garden figures. These look well at the end of a path or grass walk, or ensconced as the genii of nooks, more especially when they have a background of clipped yew; but they can be equally effective in the centre of a lawn or as the dominating feature of a fountain pool. In the tangled growth of a garden wilderness it is engaging to create the surprise of a figure of Pan.

Tubs and boxes have a certain rotundity about them which is pleasant, more especially when they hold the earth for some exotic plant which has to be protected from the cold. To weather well, they should

Horsecombe Quarries.

ORNAMENTS AND FURNITURE OF BATH STONE.

Usually they are designed to be set on terrace pedestals or walls, but there is no reason why they should not be judiciously placed, for example, at the four corners of a lawn. They are made in great variety of shapes and their materials may be lead, cement, terra cotta or stone. Large earthenware jars, those first cousins of the vase, can be used with excellent effect as garden ornaments.

There is a lively charm about a dovecote which furthers its claims to be considered as an ornament of the garden, for it combines decorative value with interest. Generally speaking, the less elaborate the design of a dovecote the better the effect.

Well-heads, water-butts and cisterns all have their place as garden ornaments. The first-named, however, demands a special setting, and not every garden offers this. Water-butts and cisterns can be set in any ordinary surroundings; and whether one prefers the "tubby" wooden plainness of the one or the beautiful designs in lead to be obtained of the other, they serve equally a practical purpose, by conserving rain-water which would otherwise be washed into the drains. The water, it is true, is apt to get dirty, but it can be filtered through sand when it is wanted for personal use and not for the garden plants. J. G.

be made of oak or teak. In a similar way, barrels can be used bored with small holes in the side and filled with earth, wherein such gay trailers as nasturtiums may flourish. Vases are, of course, entirely formal.

A SMALL BIRD-BATH SUITABLE FOR PLACING ON A LAWN.

WHAT OUR READERS SAY

WATER HENS AND GOLDFISH.

SIR,—With reference to the article (page 381) in THE GARDEN of June 11th, 1927, I may mention that in our garden we thrice put goldfish into a securely closed pond and yet the fish have always disappeared. Water hens occasionally visit the pond. Can they have taken the fish? We have not seen them do it, but there are no other intruders to the pond. A leading ornithological authority informs me he never heard of water hens taking fish, and he is quite sure they would not swallow them. However, I saw one of the fish dead with a wound in its side.—ROSYTH.

THE WINTER DAFFODIL.

SIR,—In connection with the notes on Sternbergia lutea (winter daffodil) in your May 28th issue, I quite agree that this plant should be more known, as it is quite easy and multiplies well in a sunny place in sandy soil. It flowers at a time when flowers are scarce, and, moreover, it stands the buffets of bad weather very well. I enclose a photograph taken last autumn. Each group represents a single bulb planted two seasons previously.—W. STEWART WACHER.

PROTECTING FRUIT TREES WITH NETS.

SIR,—Your correspondent "S. L. B." in THE GARDEN of June 18th recommends tying nets over fruit bushes to protect them from birds, but there are two drawbacks to this plan. One is that the birds can help themselves to a good deal of fruit through the mesh of the netting, the other, that if they *do* discover a gap large enough to get through, they will not only eat the fruit, but may entangle their claws in the netting and, not being able to get free, die from fright or thirst. Since finding a dead blackbird caught in one of our nets we have given them up. This year we are having an enclosure of wire netting made to protect most of the fruit, and, for outlying bushes, are using old lace curtains, and old mosquito net, etc.—G. F. J., *Berkshire*.

PRIMULA MICRODONTA ALPICOLA.

SIR,—I bought a plant of this name at the end of the Chelsea Show last month. I was told that Captain Kingdon Ward had seen the plant and formed the opinion that it was not the true P. microdonta alpicola, but a hybrid, probably between P. microdonta and P. Florindæ, as Dr. Macwatt suggests.—R. BEVAN, *Harrow*.

THE GOLDEN-HOODED ARUM.

SIR,—Reference was recently made in THE GARDEN to this remarkable arum (Lysichitum camtschatcense) having been exhibited at Vincent Square. It may interest readers to know that I have grown the plant for several years at the edge of the water and found it in every way satisfactory. It appears to be perfectly hardy and not at all fastidious, any moist soil and fairly open position suiting it admirably, but some shelter from cutting winds and spring frosts may be advisable in some localities. I first saw this handsome aroid in its native bog (near Victoria, B.C.) and shall not forget the wonderful golden spathes rising to about 15ins. in height and the splendid glaucous, or cabbage-green leaves which follow, these latter alone being sufficiently ornamental to afford this species a prominent place among kindred subjects. Here L. camtschatcense never fails to flower freely, usually at the end of April. The blossoms are followed by bold clubs of seed which, when mature, sink to the ground and ripen in a mass of transparent jelly, like frogs' spawn. These seeds germinate in the open and the ease with which plants can be thus raised makes it the more surprising that such a fine subject is not more widely grown.—A. T. JOHNSON, *N. Wales*.

FLOURISHING CLUMPS OF THE AUTUMN FLOWERING STERNBERGIA LUTEA.

HOLLYHOCK RUST.

SIR,—In your answer (June 25th) to "M. M.," of Sevenoaks, you state that there is "no cure" for Puccinia malvacearum. I should like to point out, however, that I grow a considerable number of these beautiful late-summer hollyhocks, both in beds and borders. While "rust" sometimes makes an appearance, I invariably find spraying with liver of sulphur very effective in checking the disease. I mix 1 oz. in about 3 gallons (a bucket) of rain water and syringe the plants hard with a fine spray. It is, of course, advisable to burn all highly infected matter.—G. N. S., *Carshalton*.

REMEDY FOR BIG BUD MITE.

SIR,—In a number of gardens big bud is the cause of great loss among black currant bushes. Numerous remedies have been recommended and tried without effect.

I had given to me, about two years ago, half a dozen two year old black currant bushes, which were rather badly affected with the mites. I tried picking and spraying with lime sulphur solution, without any improvement.

When syringing my apple trees last January with the tar oil wash Carbo-Krimp (1 to 10), I also gave the black currant bushes and ground around them a thorough washing with Carbo-Krimp, using the same strength wash as for the apple trees. I expected the bushes to be killed, but was agreeably surprised to find them unharmed when growth commenced in spring. The malformed buds gradually died off and the bushes are now clear of big bud mite and bearing a crop of black currants. I would recommend those whose bushes are affected with big bud to try the above remedy.—T. V. C., *Uxbridge*.

PRIMULA OBCONICA: A REMEDY.

SIR,—Having read in THE GARDEN for June 18th about Primula obconica and its poisonous properties, I send you a remedy for the rash which I found cured it, and may, therefore, be of use to other of your readers.

The following is the remedy, to be applied as soon as the hands have come in contact with the primula leaves: Bathe affected part with very hot water containing 1 teaspoonful of boric acid powder; then apply methylated spirit with a sponge, which will take out the irritation.—M. A. NEWINGTON, *Sussex*.

OUR PHOTOGRAPHIC COMPETITION

We have already called attention to the fact that the photographs that are likely to be accepted are those which will prove instructive and interesting to other garden lovers. On this occasion we publish a photograph showing what may be done in the way of beautifying an unsightly corner in the garden. There are many such existing in almost every garden, as for example, along a tradesman's path, a garage entrance, a drive round the back of the house and so on. We feel sure many of our readers have found ways of making these unsightly places attractive and that photographs exist showing the result of their efforts. These, if published, with the experiences of the reader given, would prove most instructive to those of our readers who are faced with the same problem. In view, also, of the article published in last week's issue on garden furniture the illustrations shown on the opposite page are interesting. They indicate how garden shelters and garden seats of simple design can be placed in the garden to distinct advantage. They lend that air of friendliness to the garden that is one of its chief charms. Doubtless many other readers have attractive pictures of furniture and ornaments used in their gardens which would be most welcome if accompanied by personal notes.

This border of forget-me-nots and tulips has been particularly effective this spring. The border, which is quite a narrow one, runs down the right-hand side of our back drive, by the stables. Delphiniums and other summer blooming perennials have been planted behind the tulips and when the latter have finished flowering, these plants take their place. In this way a succession of blooms is obtained over a long period.

The guinea photograph, sent in by MISS M. HUGHES, *Lea Hall, Mollington, near Chester.*

This photograph shows a corner of my rockery. In the foreground can be seen flourishing clumps of Linum arboreum and Aster alpinus. The linum, which is three years old, has made a fine bush; it is a mass of yellow bloom and is quite hardy. On the right near the asters are mauve and purple aubrietia and stachys. C. UNDERHILL, *Canterbury*. Award of 5s.

Digitized by Google

This snapshot of our rock bank was taken quite recently. The dry wall and crazy steps in the foreground were erected by us just a year ago and in such short time they are well clothed with plants. They have been a picture since February. Several varieties of aubrietias, anemones, bulbs, Nepeta Mussini, cerastiums, have all flowered well and some are still in bloom. At the foot of the wall is a row of St. Brigid anemones, raised from seed two years ago. MRS. P. S. RICHARDS, *Swindon.* Award of 5s.

On the rockery in front of the garden house, maples in copper and green are planted. These form a pleasant contrast to the soft red of the old pantiles which roof the garden house, up which is planted a clematis and a wistaria. MISS BLACKBURN, *Harrogate.* Award of 5s.

Many happy hours are spent in this summer house, which is both light and airy. It overlooks a delightful bed of deep blue forget-me-nots. Stocks in all their many colourings, are growing in the left-hand border; while white double daisies, pinks, saxifrages, etc., flourish in the crevices of the crazy paving on the right. MISS G. DARRAH, *Marple, Cheshire.* Award of 5s.

The raised path, pergola, stone wall and also the summer house, were designed and laid out by me. The large tree on the left is a pear, which is about seventy years old, and I think its placing is particularly effective. It provides just that necessary shade during the summer and does not interfere with the cultivation of the plants. Trees are always to be welcomed in the garden, for if they are placed with regard to their surroundings the garden is made more attractive and inviting. F. TALIESIN REES, *Birkenhead.* Award of 5s.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE old saying that "delays are dangerous," is particularly applicable to the protection of garden plants, and those amateurs who put off to a more convenient season the elementary work of staking and tying will now have reason to regret their dilatoriness, for a summer gale, with characteristic suddenness, swept the country on Midsummer week and left devastation in its trail. Lupins, delphiniums and other tall flowering subjects, suffered most, but sweet peas, dahlias, chrysanthemums, etc., also bore evidence of the damaging force of the wind. This latest example of the vagaries of summer weather in Scotland has further disheartened those gardeners who postulate that it is hardly worth while trying to grow flowers or fruit in such a climate. Admittedly the weather has been exceptionally trying during the first half of 1927, but a true perspective is seldom to be got during transient periods of depression. Plant life in the vigour of youth is endowed by nature with recuperative powers that diminishes with age, consequently annuals and biennials survive the vicissitudes of weather in May and June which would terminate their existence in August. Pessimists seldom make successful gardeners.

Notwithstanding the unseasonable weather, bloom is becoming more plentiful in the garden. My sweet peas are beginning to show colour and in the rose beds Mme. E. Herriot, Mrs. Courtney Page, Mrs. Wemyss Quin and a new crimson raised by Peter Lambert of Trier, are in flower. Growth may not be so vigorous as one would desire, but the foliage, though somewhat scant, is healthy looking and clean. Green fly, maggot and other insect pests have been successfully controlled by systematic spraying and the condition of the buds gives promise of abundant bloom in July.

Mention of sweet peas recalls one or two cultural points on which the inexperienced grower usually seeks guidance at this season. The first refers to the removal of the first blooms. Broadly speaking growers may be divided into two classes, *viz.*, those who do not practise disbudding and those who sacrifice all flowers produced in the early stages of growth. The former represents a fairly large constituency, to whom quantity is more desirable than quality; while the latter are inspired by the desire for superior flowers. Usually the plants begin to bloom when they have reached a height of about 2ft. and at that stage the stems are short and seldom carry more than two or three medium-sized flowers, and for that reason I never hesitate to practise disbudding until such time as the haulm is 3ft. high. This is a good rule to follow, especially in the case of February sown peas, that are not of robust growth. The question of feeding is much more simple, as stimulants in any form should never be given until the plants begin to bloom. Overfeeding, like over-watering, must be studiously avoided, particularly in heavy soils. Where the ground has been trenched and enriched in winter or early spring, and the plants are in a healthy condition and flowering freely, sooty water reduced to a consistency of weak tea may be sufficient to maintain the plants in a healthy condition; but liquid manure is beneficial when the blooms show visible signs of deterioration. Mr. Unwin, in his book, advocates a mulch of well decayed manure or spent hops as a means of conserving the moisture and keeping the surface roots cool.

The inauguration of the Scottish circuit of flower shows is at hand. In accordance with custom, it opens on the 16th with the exhibition of the West Lothian Pansy and Viola Association, which is to be held this year at Linlithgow, while Falkirk Rose Show takes place on the following Saturday. In this connection it is interesting to note that Messrs. Austin and McAslan's annual list of fixtures, just published and distributed gratis, contains a list of over 200 summer and autumn shows, and of that number, sixteen are to be held in Glasgow, irrespective of the Scottish National Sweet Pea, Rose and Carnation Society and the Glasgow and West of Scotland Horticultural Society.

Mr. George Mair, the grand old man of the Scottish nursery trade, has "crossed the bourne from which no traveller returns." He had a striking personality. Something like fifty years have elapsed since he entered into occupation of the then small nursery at Prestwick, which in these early days was a small, unimportant seaside resort and throughout the long, intervening period, he specialised in the hybridisation of the gladioli. Progress at first was slow, but he never lost confidence in the future popularity of the flower or the ultimate success of his work. To-day Mair's hybrids are familiar to every member of the trade and are distributed annually all over the world. His exhibits were an attractive feature of the leading flower shows and in this connection he created a record which is probably unprecedented in the realms of horticulture. During the thirty-six years he competed at Glasgow in the class for twelve vases of gladioli, he only failed on one occasion to secure the first prize award, his successful opponent in that particular year being the late Mr. Campbell of Gourock. As an indication of initiative, it may be related that when war broke out, Mr. Mair began the cultivation of white heather on a large scale and as the emblem of luck formed part of the contents of the parcels sent from Scotland to the various areas of conflict the enterprise was rewarded beyond expectation. As the gladioli trade increased, additional land was acquired and the work will be continued by his sons, who were associated with the father in the development of the business. ST. MUNGO.

GREENHOUSE NOTES

Potting Begonias for Winter Flowering.

THE class to which these begonias belong is now regarded as one of the most beautiful and most useful of all. It is not of much use any amateur attempting to grow the plants well if he cannot command a night temperature of at least 50° during the winter. The young plants rooted last spring will now be in good condition for repotting the most forward ones in their flowering pots, the others in intermediate sized ones. None need be finally potted in pots larger than 6in. ones. Fibrous loam two parts, sweet leaf-soil one part and some well rotted manure one part will form a suitable compost. The sand used to make the compost porous should be coarse, washed and dried before it is added to the bulk of soil. Low houses, or pits, from which the early melon or cucumber crops have been cleared from ideal structures in which to house the plants at this stage. But, of course, failing such houses frames or stages in greenhouses must be utilised. There must be some shade afforded or the soil in the pots will get dry too quickly and the immediate surroundings of the plants too. Quite sound drainage of every pot is essential, and pots and crocks should be clean and dry. Press down the new compost firmly with the fingers, it is not advisable to use a potting-stick. Place the pots on a bed of well washed ashes, ventilate and water carefully.

Propagating and Potting Show and Fancy Pelargoniums.

THESE large-flowered pelargonium are most valuable for the greenhouse, glass porch and conservatory. Old plants and those of one year's growth are partly cut back after the flowers have faded and the best of the branches are divided and cut to form cuttings, which are inserted in just the same way as those of the zonal pelargonium. The earliest batch of cuttings will be nearly rooted by this date, and the batch propagated now will form late-flowering specimens that will be useful on small stages and for placing in small vases in the dwelling-house. All cuttings inserted now should be of the youngest wood, the stem being severed from the harder wood of the parent plant; then the new growth will be free. Good fibrous loam, leaf-soil and sand in equal proportions should be thoroughly mixed and placed in the smallest pots—72's. Insert one cutting near the side of each pot; pack together all the pots containing the inserted cuttings in finely sifted leaf-soil or in coconut fibre in a shallow box, water and place the box on a stage in a greenhouse or in a cold frame. When the cuttings are well rooted they can be potted on without any check to their roots. The old plants that have been pruned and rested should be placed in an upright position in a sunny quarter, watered and allowed to produce some new shoots so that when the latter are about 1 in. long the old balls of soil can be reduced and the plants repotted in smaller pots, to be in due course again shifted to larger pots, when they will soon become good bushy specimens.—HANTS.

How to Fumigate and Vaporise Greenhouse Plants.

AT this time of the year aphides and red spider, also thrips, increase rapidly on the leaves and young shoots of plants grown under glass. These pests suck the juices out of the stems and leaves, thus crippling growth and hindering healthy root action. When the first few aphides are seen they should be killed instantly; a small dose will suffice in such cases better than large ones when the insects get a firm hold on the plants. Suitable materials for the purpose are sold by firms advertising in THE GARDEN, and they may be relied upon if used according to the directions accompanying each kind. I only intend to refer to the way in which the remedies should be applied—time, conditions of plants and weather at the moment. In every case the weather should be calm and the structures must be closed. This can only be safely done after sunset, as sun shining on the house while fumigation is being done, would cause injury to the foliage. If the evening is dull and showery, the glass overlaps will be closed by moisture and thus help to retain the fumes. Fumigation, in moderation, on two successive evenings will prove more effective than one big dose on one evening only. It is important that the ventilation be early and gradual the following morning, especially if the day breaks bright and sunny.—G. G.

THE FRUIT AND KITCHEN GARDEN

Notes on Strawberry Cultivation.

WHERE it is intended to make new strawberry beds, consideration must now be given to selecting the strongest runners and pegging these down in large 60-size pots filled with some old potting soil or similar material. Attention must also be directed towards the plot the new bed is to occupy, which should be well trenched and manured some time beforehand, working into the top spit a good sprinkling of soot and bone meal.

When the plants have rooted freely in the pots they must be severed from the parent plant and collected in a place by themselves for a week or so until going strongly on their own roots, when they may be safely planted in their permanent quarters. Tread the soil firmly before each plant is put in, make sure that the crowns are well exposed when planting is completed and water them well in. Follow this by the use of the Dutch hoe in loosening the surface soil, thereby conserving the moisture and keeping the soil well aerated and free from weeds. The hoe should be used frequently, and every encouragement given to keep the plants growing freely, removing all runners as they appear.

Spring Cabbages: July Sowing.

THIS is such an important crop that it is always wise to make two sowings, one about the third week of July and the other three weeks later. Prepare special beds for the seeds and distribute them thinly on a firm level base; commence thinning directly the plants are large enough to handle, as sturdy growth is essential to success. If the permanent positions are not ready by the time the thinned plants touch each other, transfer them to nursery beds, planting them firmly, and later set them out. This plan may involve a little extra trouble, but it will often make all the difference between success and failure in the spring cabbage crop.—L. B.

Plant Out Brussels Sprouts.

NO time should be lost in getting the plants of Brussels sprouts sown in March into their permanent quarters. Land which is to be given over to this crop should be fairly rich, and it is most important to have it deeply dug. The ground needs to be firm, and, if it has been dug during a dry spell, it is a good plan to roll or beat it down to make the surface somewhat solid. Brussels sprouts do not produce stout stems in loose soil, and without these the heavy production of close sprouts is not possible. Have the rows about 30ins. apart, and let there be from 20 to 24 inches between each plant. If the land is in very good order more space may be allowed with advantage. Apply a dressing of lime before working up the ground for planting and, if possible, settle the plants in during a moist spell. If the weather is very dry each plant should be puddled in, and waterings at a later stage will be highly beneficial.

How to Grow Fine Endive for Autumn and Winter.

ENDIVE forms a most valuable crop in the garden, but justice is rarely done to the plants. They are hardier than lettuce, but repay the cultivators well if they are properly treated. It is a mistake to grow plants too early in the season. In naturally rich, moist ground the first sowings may be made in June; in a drier, poorer soil the early part of July will be soon enough. For the earliest supplies the fine curled varieties may be grown, as there is less risk of loss in frosty weather in the case of the round-leaved Batavian, and the latter should therefore, be grown to withstand the winter season and the early part of spring. The end of July will be a suitable time for sowing seeds of the round-leaved Batavian. Two sowings will be advisable as stated above. Ground recently cleared of early potatoes will be ideal for endive. It will only be necessary to level and break down the lumps of soil so that drills 1ft. apart can be opened with a draw-hoe. Endive seed is cheap, and where the ground is now available it is more economical to sow the seeds thinly in the shallow drills and thin out the resultant seedlings than to sow in beds or boxes and transplant the seedlings. Transplanted seedlings run to seed sooner than those not transplanted. Firm ground is essential for endive plants, then the outer leaves are smaller and those forming the heart, or centre, larger, thus there is a considerable gain to the cultivator. The curled-leaved should be thinned out to 9ins. apart and the Round-leaved Batavian to 1ft.—HANTS.

Some Vegetable Seeds to Sow Now.

IN some districts cultivators have experienced much disappointment this year owing to a long spell of dry weather preventing the free growth of young vegetables. By sowing now a few rows of early maturing varieties of certain kinds really good tender vegetables may be obtained late in the year, and they will be much appreciated. There must not be any transplanting of seedlings. All plants should be left in their seed drills, being duly thinned out only. Seedlings resultant from seeds sown early in June are now advanced far enough to be thinned out. There should not be any delay in carrying out this important work, as when seedlings become large and are then uprooted their removal unduly disturbs those seedlings retained. When seedlings are transplanted the check given to them causes a month's delay in the maturing of the crop for use. Early in the year we thin out seedlings of beet to 9ins. apart, but now we need only thin them to 6ins. The roots will be smaller but of high quality. The principal seeds to sow now are those of globe beet, stump-rooted carrot, Early Milan or other early turnip, such as White Model or Golden Ball; Broad Batavian endive, kohl-rabi (green for preference) early cabbage lettuce White Queen and Paris Silver-skin onion earliest pea, summer or round-seeded spinach, and turnip-rooted and French Breakfast radish. The best winter and spring crop of parsley is generally raised from seeds sown now. Not only do vegetables grow rapidly at this season because the soil is very warm but seedling weeds also, and these should be destroyed while quite small.—GEO. GARNER.

Treatment of Onions.

THE onion, like the cabbage tribe, is a gross feeder, hence to get the best results the soil should be rich or otherwise well fertilised. A sprinkling of nitrate of soda two or three times during showery weather stimulates growth. This crop also responds well to applications of liquid manure. A simple and practical way of obtaining liquid manure is to suspend a small bag of soot, sheep droppings or other fertilising matter in a tub of water.

The chief difficulties to contend with in growing onions are the onion fly and mildew. There appear to be various ways of coping with this fly pest. Among the simplest and most effectual remedies is elderberry leaves, a decoction from those being applied from a watering can at intervals during the early stages of growth. A successful gardener known to the writer makes a practice of digging in the green leaves of the elderberry in early autumn, by which means the soil becomes permeated with the odour; while another neighbouring gardener sows parsley with his onions.

Mildew, fortunately, is not general, although some districts seem to suffer more than others, it being more prevalent in humid weather. Keeping the ground firm and allowing plenty of room between the plants in order that they may get a sufficiency of sun and air is helpful, the object being to encourage the growth of hardy plants.

The crop should be lifted on the first dry day after the stalks have died down. If the weather is dry, the onions are benefited by a day or two outside, otherwise they should be spread on a dry floor under cover and well dried before being tied up for the winter use.—G. S. T.

Trouble with Peas.

GARDEN peas are, as a rule, singularly free from trouble, but at times one may be severely tried by the appearance of certain pests. A species of thrips may arrive suddenly in warm, droughty weather. These tiny insects infest the leaves in countless numbers, suck sap from them, cause them to flag at first and latterly to become blotched, unsightly and sickly. The application of water twice a day gradually removes them, but an insecticide is speedier and very effective. Always keep the syringe and the watering can going when thrips are about. The weevils are also annoying visitors. The grubs of these weevils live in the ground and attack the roots, while the mature insects nibble away at the leaves, eating little portions from them and quickly reducing their vitality. As they feed at night they are seldom seen, and the tyro wonders what the pest is. First of all tramp the ground alongside the rows, then dust lime or soot, preferably the former, in round the roots. Occasionally in the evening spray with paraffin emulsion or other insecticide as a further precaution and apply a stimulant in liquid form to urge the plants on.—H. H. A.

THE AMATEUR SHOW

THIS, the third amateur flower show arranged by the Royal Horticultural Society, much more nearly approached the ideal. Many real amateur gardeners took advantage of the opportunity to enter into friendly competition with the floral products of their gardens. Perhaps when the new hall is ready the R.H.S. will arrange classes for seasonable fruit and vegetables, and then, judging from the success of this year's show, it will be the ideal amateur show.

Sweet peas were the outstanding feature of the Show. The prize-winning collections were of such superb quality that many really splendid vases were not "in the running." The dozen vases of Youth, Magnet, Constance Hinton, Mammoth, Daventry, Picture and other sorts staged by Mr. F. W. Franks, Loampits, Tonbridge, were of such excellence as to be adjudged the finest individual exhibit in the whole of the Show and, in addition to the first prize, received the Garden Club Cup and the National Sweet Pea Society's silver-gilt medal. Major Krabbe of Calcot Grange, Berks, was a worthy second in this important class. In the other divisions Mr. William Huffey, Boormans, Tonbridge, and Mr. C. W. Renn, Clewer, also had magnificent first prize sweet peas.

Next to the sweet peas we should place the sprays of hardy shrubs. A few of the critical visitors questioned the hardiness

Digitized by Google

of some of the genera which were admitted. But hardy is a relative term, and we conclude that any gardener is justified in exhibiting shrubs which survive the winter unprotected in his garden. The leptospermums were mostly instanced, and of these we have seen self-sown seedlings growing around the parent bushes in the home counties. But the show is the thing, and the exhibits of cut sprays of shrubs were passing beautiful. In the principal class the judges could not make up their minds, and so compromised by placing Mr. Lionel de Rothschild and Mr. Gerald Loder equal firsts. The former had Zenobia pulverulenta, Olearia semi-dentata, Magnolia macrophylla, Leptospermum Chapmanii and Carpenteria californica, while Mr. Loder included Leptospermum ericoides, L. Nicholsii, Veronica amplexicaulis and Callistemon salignus.

In appraising the Show, roses should certainly be placed at least third, and in the opinion of the expert judges the quality was much higher than, in view of the season, they expected. That veteran and enthusiastic exhibitor the Rev. F. R. Burnside, Stambridge Rectory, had most lovely blooms of Mme. Mélanie Soupert, Rev. F. Page Roberts, Dean Hole, Ramon de Escofet and Mrs. Henry Bowles. Mr. C. H. W. Maunder showed splendid blooms of George Dickson, Etoile d'Hollande, Augustus Hartmann, Cupid and Lemon Pillar; while Mrs. Ethel M. Wightman, Mr. C. H. Rigg and Mrs. Cribb also had delightful exhibits of roses.

The exhibits of border flowers filled large spaces, and practically all evidenced very good cultivation, but, with few exceptions, they were of the ordinary sorts that are to be seen in the average garden. Mr. Lionel de Rothschild, who won the chief prize, included the beautiful blue Razzia orientalis, Clematis integrifolia cœrulea and the arum lily. To the latter some took exception, but it, and also the Allium giganteum, were definitely allowed by the schedule. Annuals were also well grown, especially the antirrhinums and marigolds. Both of the first prize winning collections of carnations were of considerable merit, and Mr. Fairlie is to be congratulated on his border carnations, while Mr. Morton set up six vases of delightful garden pinks.

The indoor plants were of equally high quality, the miscellaneous groups being most decorative. The first prize was won by Mr. A. P. Brandt, Bletchingley Castle, with a charming arrangement of highly coloured crotons, graceful palms and ferns, liliums and Tydæa amabilis. The exhibit from the gardens of the Cheadle Mental Hospital were a very good second, and this contained the graceful Humea elegans, crotons, dracænas, coleus and liliums. The nine foliage plants which won the first prize for Mr. F. C. Stoop, West Hall, Byfleet, were all excellent specimens. Mr. T. Crawford sent from Bristol six excellent double-flowered begonias.

The classes for new plants introduced since 1920 were interesting but did not contain any epoch-making specimen. The best new species was Calceolaria filicaulis, shown by Sir William Lawrence, Bt. This is very like, but inferior to, the Andean calceolaria, which received an award of merit when shown by Mr. Clarence Elliott a week previously. Colonel Grey was placed second with a greyish-leaved form of the same plant. Mr. Lionel de Rothschild was placed third with Rhododendron didymum, an interesting and attractive Chinese species. It has a good truss of bell-like, reddish maroon flowers.

The best new garden plant was the handsome Disa Pink Domino shown by Colonel Stephenson Clarke.

Strelitzia juncæfolia, shown by Sir William Lawrence, was the best plant "not mentioned in the schedule." It was well grown and interesting, but not of general garden value. Mr. Lionel de Rothschild was second with a large vase of leaves and inflorescences of the New Zealand flax, and Mrs. Carl Holmes was third with Begonia Cathayana, a handsome greenhouse plant.

NEW AND RARE PLANTS.

BOTH sections of the Floral Committee of the Royal Horticultural Society met on the occasion of the Amateur Show, when they considered the merits of a number of new or rare plants and made three awards of merit.

Eucomis bicolor, shown by Mrs. Carl Holmes, The Node, Welwyn, is an uncommon bulbous plant introduced from Natal in 1878. Mrs. Holmes showed a very well grown plant bearing robust, erect, cylindrical racemes of whitish flowers wh have blue-purple filaments. Although a showy plant, it is attractive and interesti and the flowers last fresh over a considera period.

Philadelphus Atlas is a large-flowe mock orange, but, unfortunately, see to lack fragrance. The round flowers op quite flat and the shrub is of grace habit. It was shown by Sir Willi Lawrence, Bt., Burford, Dorking.

Veronica Matthewsii is a graceful lit shrubby species from New Zealand and suitable for planting in the rock garden the front of the chrubbery border. It w shown by Messrs. Wallace and Co., a has plentiful spikes of small white flowers ve lightly flushed with lilac.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2902 Saturday, July 16th. 1927 Price TWOPENCE

A LOW WALL MADE BRIGHT WITH SPRING FLOWERING PLANTS.

ATTENTION must be given now to preparations for the garden display next spring. Wallflower and polyanthus seed should already have been sown and the seedlings now require thinning and transplanting. Aubretias and other similar spreading plants must be cut back after flowering and cuttings taken this month to ensure a stock for next year. The multi-coloured polyanthus primroses, which are of easy culture, and the modern varieties of wallflowers should be in every spring display

THE GARDEN

VOL. XCI.—No. 2902. JULY 16, 1927. PRICE TWOPENCE.

HINTS FOR AMATEUR EXHIBITORS

IT is fairly safe to say that every town and village in the land has its annual show of garden produce. In some districts the show is the biggest social event of the year. Many of them are coming along just at this time, and a few hints as to the points which a judge looks for in the different classes may be useful to amateurs.

FRUITS should be a little above the average size of the variety, the name of which should always be given. The flavour should be good and the colour, form and condition perfect. Uniformity is looked for in a dish of fruit, and the bloom should still be on plums, grapes, apples and such fruit. Defects in fruits are badly shaped specimens, or fruits of enormous size (in the case of dessert apples, for instance), spots, blemishes or bruises.

FLOWERS, at the time of judging, should display the full size and characteristic of the variety. Brightness, true form, substance and healthy foliage are essential. Flowers generally display best with their own foliage.

VEGETABLES must be clean and fresh, free from blemish, of good quality and of a size suitable for table use. Samples in the same dish should be of even size, and in all cases the size should not be too big. Tenderness is the chief point in beans, peas, etc. Common defects are tough and overgrown marrows, thick necked onions and coarseness, the last being due to a desire to show the largest.

READ THE SCHEDULE, or your exhibit may be disqualified. One phrase in schedules provides a snag for the unwary. Distinct "kinds" of flowers means genera like roses and sweet peas. Distinct "varieties" means different sorts of one genus, like Youth and Sunset among sweet peas. Varieties of plants do better in some localities than in others, and the easiest way to ascertain the best fruit, flowers and vegetables to grow in your own garden is to visit the local show.

All flowers and vegetables should be named. This is an important point to remember in exhibiting garden produce. Where two otherwise equal exhibits are entered in the same class, naturally the judge will give the first prize to that which is correctly labelled, as this adds to the real object of the exhibit, *i.e.*, to spread a knowledge of horticulture.

Trials of Roses.

THE question of establishing trials of seedlings under the supervision of the National Rose Society is presently receiving consideration by the Committee of that influential body and as the procedure of testing new introductions prior to the bestowal of honours is essentially sound, it is in the interests of all rosarians, whether they belong to the vast body of amateur growers or the less numerous class of traders engaged in the raising of novelties, that a practical scheme, more in keeping with the spirit of the times, should be evolved and put into operation in the near future. On the principle that the proof of the pudding is the freeing of it, the merits of a new flower can best be judged by the growing of it. The practice is by no means new. It has been in operation at Bagatelle, Paris, for quite a number of years and it is also followed by the English and Scottish Sweet Pea Societies. A two years trial is imposed by the French and a similar period of observation is favoured in this country. As an encouragement to raisers, the present system of awarding honours when the specimen blooms and bush are staged for the first time will probably be continued, but a super-award given after a two years' test would be the best guarantee of the qualities of a rose for garden decoration, which growers throughout the country might interpret as the hall mark of good character. Such a scheme would inspire a confidence in the decisions of the judges which could hardly be expected in the present method of distributing honours; and as its success as a guide to the selection of varieties would be reflected in the extent of the demand not only on the part of the 15,000 to 20,000 members of the Society, but by the rose loving public in general, it is more than probable that the future cultivation of the Queen of Flowers will, in a more or less degree, be restricted to those sorts whose merits are proved to be beyond dispute. The Society, we understand, have received the offer of a suitable site, and on very favourable terms, and although no definite arrangement has been made, it may be concluded that the practical work associated with the trials will be entrusted to the capable secretary, Mr. Courtney Page, who has had long years of experience as a practical rose grower.

The Jones-Bateman Cup.

IN 1920 Miss L. Jones-Bateman of Cae Glass, Abergele, presented to the Royal Horticultural Society a valuable silver-gilt replica of the Warwick Vase, to be used for the encouragement of fruit production. It is accordingly decided to offer it triennially for researches in the growing of hardy fruits figs, grapes and peaches in the open or under glass, and it is available for award in 1927.

Candidates should submit accounts of their work by October 31st. The work dealt with must have been carried out by the candidate in the United Kingdom mainly during the past five years. The Cup will be held for three years by the successful candidate, and when the Cup is relinquished the holder will receive a gold medal.

This Week's Work

For Gardens in the South and Midlands.

Stake tall-growing autumn-flowering perennials in the herbaceous border.

Layer border carnations, pinks and strawberries.

Repot old cyclamen corms.

Sow seed of greenhouse primulas and schizanthus in pans and place in a cool greenhouse.

Thin shoots of vegetable marrow and cucumbers, and keep the beds well watered.

Continue to summer prune fruit trees by shortening the side growths.

Lift shallots when mature and place them in a sunny position to dry.

Keep roses sprayed against insect pests.

Sow seed of hardy perennials in a shady border.

This Week's Work

For Gardens in Scotland and the North.

Sow Spring Cabbage.

Take cuttings of border pinks.

Top-dress dahlias when showing bloom.

Begin summer pruning of fruit trees.

Remove strawberry runners that are not required.

Lift shallots that are thoroughly ripened.

Plant out savoys and kale.

Continue layering border carnations.

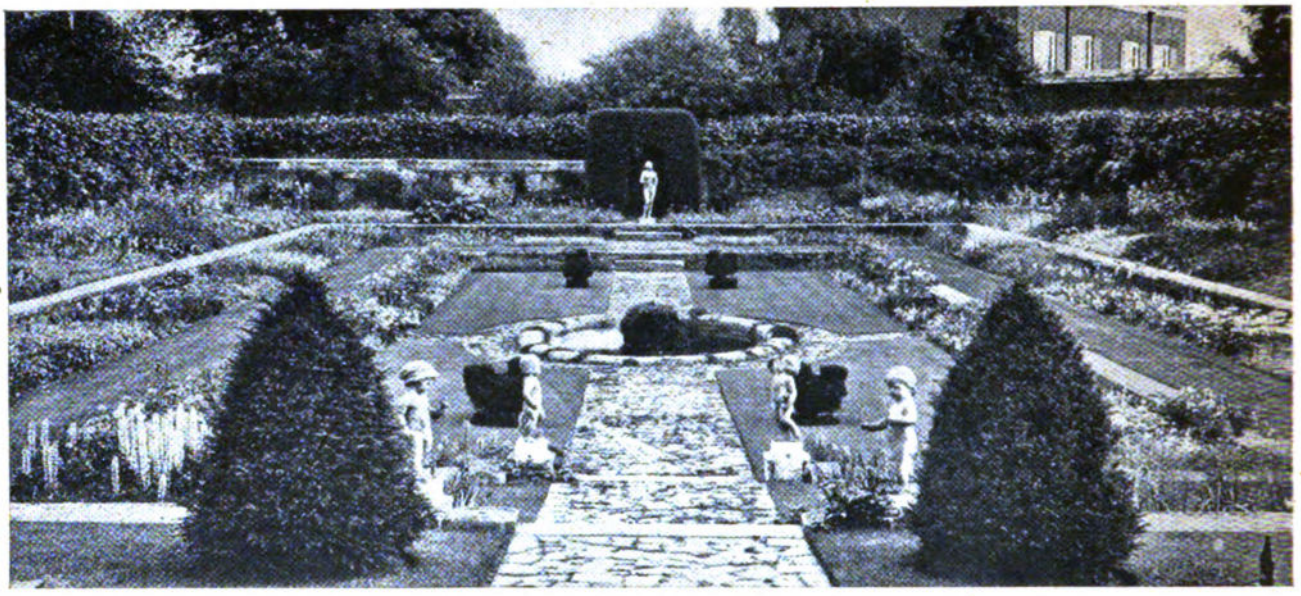
Sow mignonette for winter flowering.

Pinch out side shoots of sweet peas and remove tendrils.

Prepare ground for new strawberry bed.

Transplant late batch of leeks.

Digitized by Google



MAKING A FORMAL SUNK GARDEN

The famous Dutch Garden at Hampton Court so often admired and coveted by amateurs can be easily adapted to meet the needs of the average suburban plot. In this article full details are given on how to proceed with the laying out and planting of such a garden in the confines of a small space.

FEW realise that the famous Dutch garden at Hampton Court is not only to be admired, but can be possessed, on a modified scale, even by a dweller in the suburbs, who has no more than a rectangular plot enclosed by the brick walls which divide him from his neighbours.

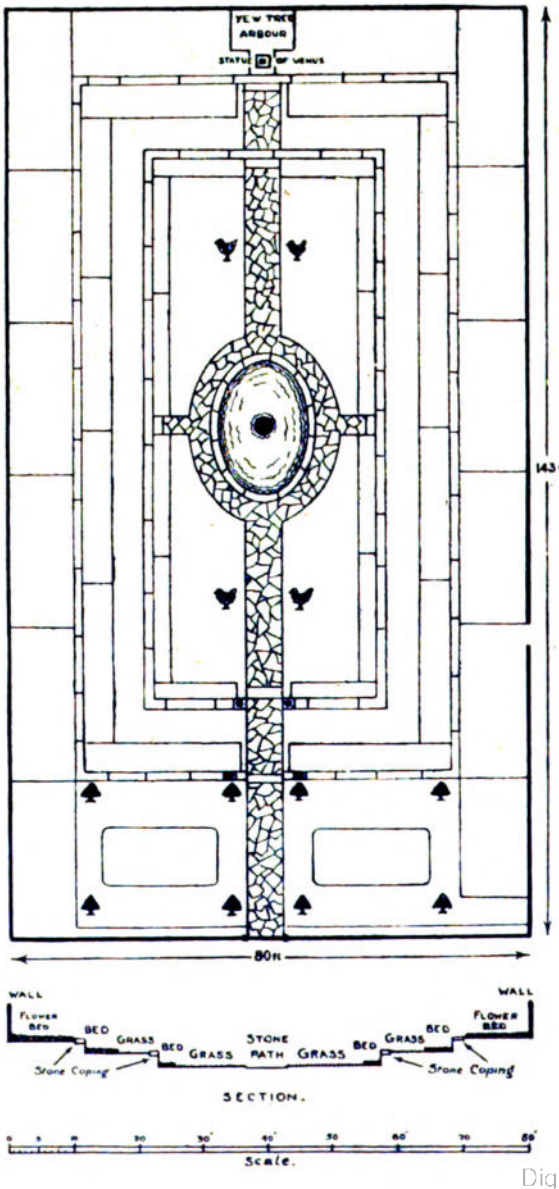
The plan may be adapted to suit both the individual purse and the size of the plot available. A very charming garden could be made by having the middle sunk portion surrounded by one tier only, or the terraced portions at either end could be omitted.

After the initial outlay in time and money, the subsequent upkeep does not demand excessive labour nor considerable expenditure on plants. If possible, go to Hampton Court and study the garden there. Note the planting arrangement, and above all, try to feel the atmosphere of the garden, so that, when it is reproduced, everything will be in harmony. The garden, it will be seen, is formed in three levels, built up by means of dwarf brick walls, each crowned with a capping of stone.

Now take the measurements of your own garden, ponder over the plan given with this article, and, after due consideration, decide whether it would be advisable to lay out an exact replica of the garden at Hampton Court, or whether to use only a portion of the plan. In either case the general procedure will be similar. Levelling tools, stone for paving, bricks for the dwarf walls, broken bricks and cinders for the path foundation, a measuring line, wooden pegs and a spirit-level will be needed. Anyone with a "good eye" can do quite accurate levelling work with a spirit-level, pegs, and three "rods," which are made in the form of the letter T and are about 4ft. high.

As a beginning, clear the plot of all plants and heel them in carefully in a corner of the garden, keeping well watered till the time comes to plant out.

The exact centre of the garden should first be found by stretching cords diagonally from the corners and marking the point where the two lines cross.



From this central point all other measurements should be taken. Each point of the whole plan should be marked on the garden by driving in stout wooden pegs. All measurements must be done accurately, every line must be parallel, and every angle a right-angle; and when all the pegs are in position, the accuracy of the lay-out should be checked by taking cross measurements. After this the work of lowering the central portion and the forming of the tiers begins.

To make the three levels in this garden, the middle one should be the original level of the garden and so be left untouched. The lower one should be dug out and the soil used to form the outer tier. It is no use digging out the middle and dumping the excavated soil on top of the back border in order to produce the three levels. This, of course, is the simplest method, but, unless the soil is of an exceptionally deep nature, it means that in most parts of the garden the top soil is being buried and in substitution for it is poor subsoil, in which few plants will grow. The top spit must be kept to the top; and although this means considerably more work, it is well worth the extra trouble. It would take several years of cultivation to bring the subsoil into sufficiently good condition to produce plants equal to those grown in the surface soil.

The best method to keep the subsoil at its correct level is to pile up the surface soil from the back border and sunk portion in the form of a ridge on top of the middle tier. The subsoil from the centre can then be wheeled out and carted to the back border until the desired depth is reached, when the surface soil should be thrown back on top from where it came, placing a good layer of well decayed manure between each spit. The middle tier must then be deeply dug and given a liberal supply of manure. If the soil is inclined to be heavy, it is advisable to provide some form of drainage for the lower portion. Trenches could be taken out and drain pipes or broken

Digitized by Google

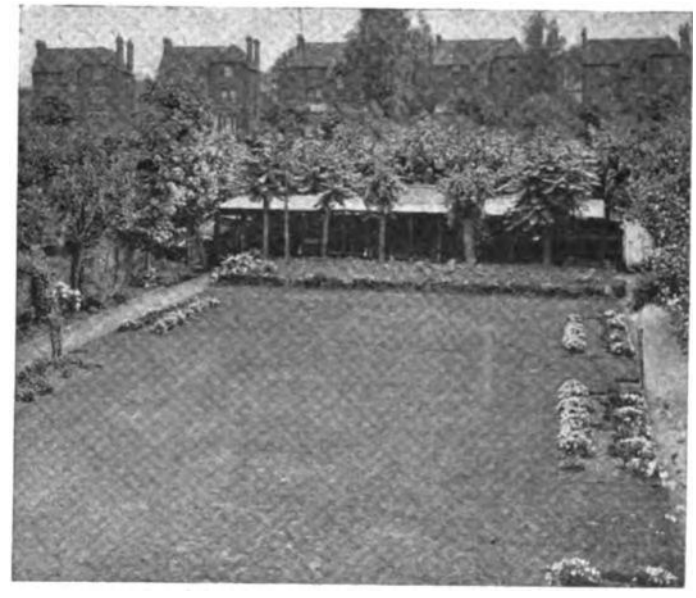
bricks put in during the operation of lowering the level.

As the work proceeds any small depression should be filled up and the surface roughly levelled. When the tiers are made up, levelling begins in earnest. Simple levelling is done by means of a series of pegs driven into the ground so that the top of each one is on a level with all the others. The soil should then be raked until all the pegs project the same distance out of the soil. The sunk portion should be levelled first, and a start made from the central point, where a peg should be driven in.

Having levelled the sunk portion, the low wall surrounding it should be built up. This wall is made by cutting a trench about 6ins. wide and 3ins. deep, filling it with concrete, and then building up on this foundation three courses of bricks, finished off with a rim of rectangular stone slabs, about 1ft. wide. When this has been done, the next tier is levelled and a similar dwarf wall built, but for this second wall four courses of bricks are used. Finally, the outer tier is levelled up to the wall. A note may be added as to the number of bricks required. The Hampton Court garden measures 143ft. by 80ft. Adapting it to a suburban plot, we may take this to be one-quarter of the area—say 70ft. by 40ft. The dwarf wall for the lower tier would be about 44ft. in length and 18ft. across, and the wall for the upper tier about 54ft. by 30ft. The walls would be built in "garden wall bond"—all "stretchers," that is to say, with the bricks laid end to end lengthwise. About 1,500 bricks would be required, costing about £4 10s. (The plan of the garden given on the opposite page has been redrawn from one which is shown in "The Flower-Lover's Guide to the Gardens of Hampton Court"—a most useful official booklet by Mr. Ernest Law, published by Messrs. George Bell and Sons; price 1s. This booklet gives detailed particulars of the planting throughout the gardens of Hampton Court, and is of the greatest interest and value to all garden lovers.)

The next procedure is to make the oval pool and the foundations of the paved paths, with their steps down from either end. The paths must have a good base of broken bricks, clinkers and sifted ashed to ensure firmness and drainage. The path foundation is left to settle before paving with either "crazy" or squared paving. When making the pond provision must be made for drainage and also for an inlet of water, which should come up through the centre in some form of fountain. The outlet pipe should reach the surface of the water, so that the overflow runs down it and through into the nearest drain, or to a soak-away.

Up to the present the work has been mainly constructional and of a heavy nature. To many the labour from now onwards is much more interesting. Turfing should be done next, but sufficient time for the ground to settle must be given. If the garden is started in the autumn (which is byfar the best time to begin), it is advisable to wait until the spring before planting the clipped yews. These do not transplant well during the late autumn, but soon become established if put in during April and given good supplies of water. The small beds can be cut and made ready when the turf is laid.



A SMALL SUBURBAN GARDEN WHICH BY REASON OF ITS SIZE AND SHAPE IS WELL ADAPTED FOR TRANSFORMATION TO A FORMAL GARDEN STYLE.

It will take time before the walls are bedecked with flowering climbers, or the yew arbour has reached any size, but by careful thought quite a good show of flowers can be obtained during the first year. Many herbaceous flowers can be planted in late autumn if the garden is finished in time. In the spring countless biennials, perennials, annuals, dahlias, gladioli, etc., can be put in, and these will bloom during the first season. Such plants as aubrietias, Lithospermum prostratum, Gypsophila repens, alyssum, iberis, etc., should find a home in the crevices of the low walls, so that they hang down in graceful trails.

The following notes give a rough idea of the plants suitable for stocking the garden, but, of course, the list is very far from complete:

In the uppermost tier: Phlox, Campanula persicifolia, anchusa, bearded irises, solidago, Oriental poppies (such as the variety Mrs. Perry), Anthemis tinctoria, Hemerocallis flava, Gypsophila paniculata, Salvia virgata, English irises, gladioli, stocks, antirrhinums, verbena, iberis, clarkia, geum, aquilegias, etc.

In the second tier: Flag irises, coreopsis, Lychnis chalcedonica, chrysanthemums, Canterbury bells, Nepeta Mussini, and drifts of annual lupin, Cheiranthus Allionii, alyssum, Papaver nudicaule, Anemone blanda and Dianthus Mrs. Sinkins towards the front.

In the lowest tier: Mixed tritonias, Spanish irises, sweet williams, Meconopsis cambrica, dianthus, Spiræa Filipendula, violas, comet asters, with rock campanulas and anemones at the edge.

In the spring bold groups of Darwin tulips would look delightful. Varieties of bright clear colouring are best for this purpose—Farncombe Sanders is a good cherry red, Clara Butt one of the best and most popular of pinks, Feu Brilliant is a very fine deep scarlet, Bartigon a rich deep red, and Euterpe a lilac mauve. Inglescombe Yellow, although not a true Darwin, associates well with any of the Darwin varieties, and it could be used with good effect in a garden of this type. The treatment of the rectangular beds at either end should be formal, and the plants should not be mixed. Intermediate or bedding antirrhinums could be used. These flower for many weeks. Flame, rose or yellow shaded varieties would be effective. Dwarf dahlias of the Coltness Gem type are also excellent. Comet or Ostrich Plume asters in pink and dark purple, stocks, zinnias, godetias and clarkias are all suitable. If one of these plants are chosen for these small beds, a seed of good quality should be sown early in the year, so that well advanced and sturdy plants are obtained by the beginning of May.

Wistaria chinensis, clematis in a great variety, lonicera, Solanum jasminoides, Jasminum officinale, Cotoneaster horizontalis, ceanothus, pyracantha, Cydonia japonica and Forsythia suspensa are only a few of the many shrubs which could be used to clothe the walls.

A number of old-fashioned flowers are particularly suitable for a garden of this kind, and, fortunately, most of them flourish exceedingly in the neighbourhood of a town.

The colour scheme should be soft and yet not insipid; a bright patch of colour here and there would relieve any tendency to monotony. Lemons, pinks, mauves, blues, purples and crimsons, with an occasional vivid orange interspersed with foliage plants of a silvery grey, would be ideal tones for a garden of this type. M. P.

SOME OF THE NEWER IRISES

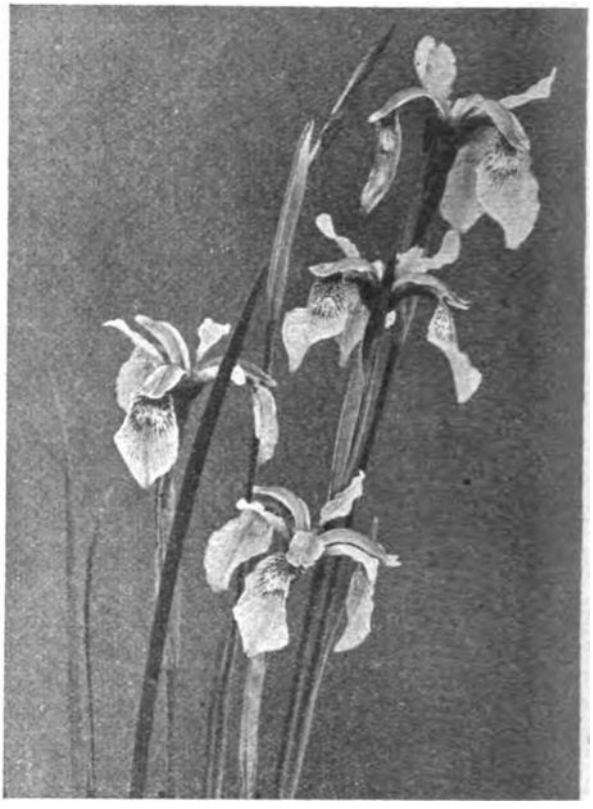
A Survey of the More Modern Varieties, Pointing Out those of Real Garden Merit.

THE tall, bearded or June-flowering iris takes an almost overwhelming proportion of the hero-worship accorded to this now popular flower; but there is plenty of scope for as yet unseen development, as may be gathered from the fact that only six or seven of the hundred and seventy odd known species have been utilised to produce the innumerable varieties of the favourite and easily grown, but inaptly named, I. germanica.

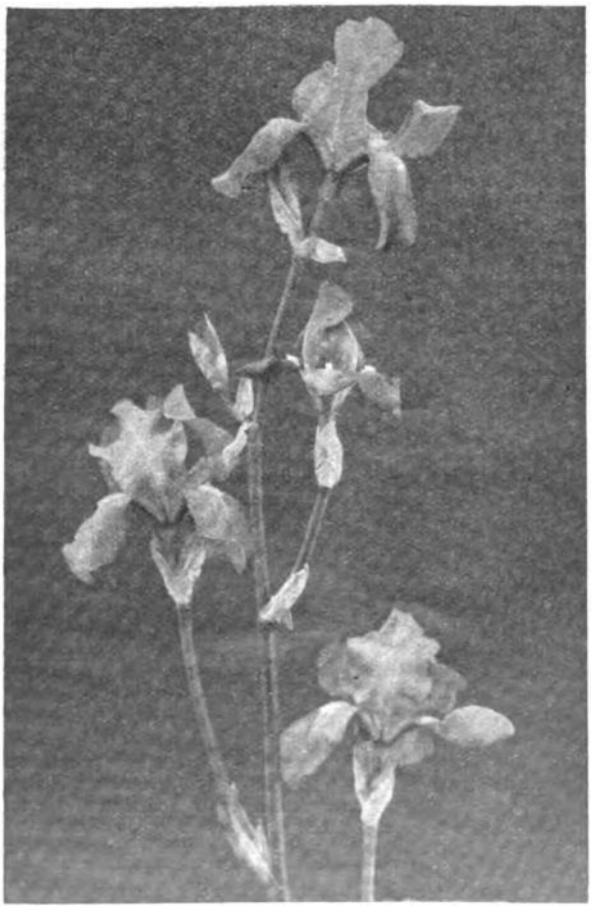
Equally accommodating, especially in heavy moist soils, and just as pretty and decorative, are the Iris sibirica types, now obtainable in a number of varying forms as garden hybrids; but it is difficult to understand why some of the other Far Eastern species—such as chrysographes and Delavayi—are so seldom met with; and the same remark applies to I. graminea, with its delightfully fragrant flowers. Some of the beautiful Californian species are notoriously difficult in English gardens, but Mr. Amos Perry of Enfield has recently produced some fine hybrids between these and I. chrysographes which promise to be more adaptable, and, should they prove so, will undoubtedly become popular.

Going back in memory to the Show of June 2nd—an exhibit which, to many of us, was an amazing effort—a hundred and one things are recalled which we shall ponder over till they meet our vision again next season. Among the new seedlings, Mrs. Dykes showed some beauties, one of them being practically a new break in colour, Zaharoon by name, and very catching to the eye. Its colour is most difficult to translate into words, but it struck me as soft apricot or biscuit curiously suffused with rosy mauve. Two new plicata seedlings were also worthy of note: Castor, shown by Messrs. Bunyard, the standards being bronzy mahogany and the falls heavily stippled crimson purple on white; and an unnamed seedling shown by Mr. Burton of Hildenborough, which seemed to me the best proportioned and most massive plicata extant. The pure white ground was heavily feathered mauve, the falls being wide and of excellent form. In Seedling 46, Messrs. Wallace had a bold pallida with soft mauve standards and deep plum purple falls margined pale purple; and Captain Troup showed a good white self, called My Own. In Mrs. Dykes' group one was pleased to see her late husband's fine yellow Amber in good form, the mauve pink Aphrodite, and Silver Mist, very pale silvery blue.

The interminable array of purple blue pallidas come from the raisers in such numbers that one gets bewildered, and oftentimes it is really difficult to detect more than a florin's worth of difference between a 42s. plant and one priced at eighteenpence. As a rest for the eye, I wandered several times back to Mr. B. R. Long's exhibit, where many of the artistically coloured varieties raised by the noted French amateur, M. Denis, could be seen. Rosa Bonheur is an example, Col. Candelot another. The latter has falls of a really rich crimson, with very little purple in its composition, and with such an achievement before us the question arises as to whether the red crimson fall may not be more imminent than we imagine: and if this colour comes, why not scarlet? Mr. Long, by the way, was surely a dark horse in this Show, and at Richmond he grows irises exceedingly well. It was a splendid and first-class performance, and gained for him the Veitch Memorial Medal for the best exhibit by an amateur. And these amateur exhibits were in the nature of very formidable competition, for the blooms and spikes shown by Sir William Lawrence, Bt., and Messrs. G. L. Pilkington and G. P. Baker were remarkable proofs of expert and painstaking cultivation. A most interesting exhibit was a group of beardless irises by Mr. Amos Perry, derived from various crosses. All the flowers were beautiful and fascinating, perhaps the most notable of all being Margot Holmes (Chrysographes x Douglasiana).



IRIS DELFOR, ONE OF MR. AMOS PERRY'S MODERN HYBRIDS.



PERHAPS THE BRIGHTEST OF PINK IRISES, THE STATELY APHRODITE, RAISED BY THE LATE W. R. DYKES.

Planting.—The public do not take kindly to the oft-repeated advice that soon after flowering is the best time to plant the bearded irises. Perhaps it is because holidays, sports and all other counter attractions of the open air take so much of the gardener's time; but experience shows that irises are as much in demand in March and April as they are in July and August. Now, from actual demonstration, plants establish themselves more thoroughly before winter sets in if placed in position from July until September, than do those planted later on; late September is a better time than the late autumn, and October is just a little more suitable than open weather during winter. Some years ago I received a small batch of American irises from Mr. Wassenberg in Van Wert, Ohio. The rhizomes came to hand perfectly dry in a large cardboard box a week before Christmas. I placed them in damp potting soil in a box, left them for a fortnight, and then had them planted out. All except one flowered strongly the following June and made excellent growth. Although I strongly urge planting in late summer, I deliberately say that the best time to plant is as soon as you make up your mind to have irises in the garden! If the inspiration comes in February or March it is better to get the rhizomes then than to wait for July, because you may get some bloom the first summer, and in any case the plants will be better established and better grown by the following year. In short, the best time to plant is *now*, whenever that may be. It simply means that plants put in during the summer become established in the shortest possible time.

Raising from Seed.—Every catalogue devoted to irises gives hints on planting and culture, so there is no need to go into these matters here; but I would like to say a word on the most interesting

Digitized by Google

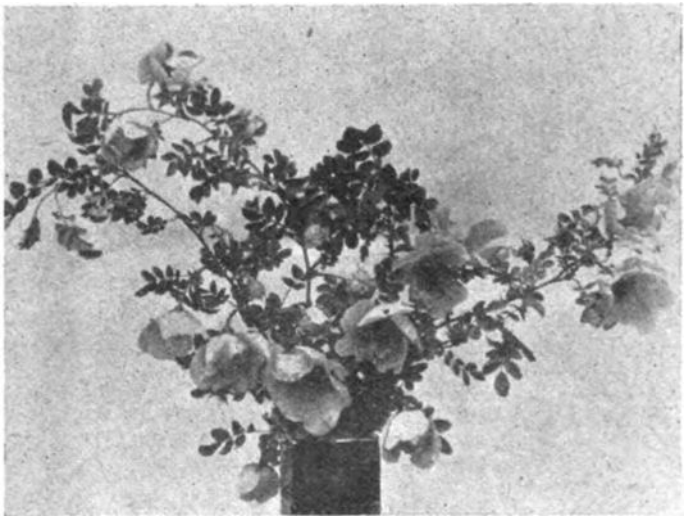
pastime of growing irises from seed. Most people imagine this to be a tedious and soul-trying experience. It is nothing of the sort. Many of the seedlings will flower eighteen months after sowing, and to watch seedlings breaking into flower is one of the real joys of gardening. The seed bed should be made quite in the open without the slightest protection, as frost expedites germination. For that reason the seed should be sown in October or November. If the natural soil is heavy and moisture-retaining, it is advisable to make a raised bed of porous soil. An old frame without lights is just the thing. A foot or so of loamy soil well treated with lime should be placed in this, and then 3ins. of mixed leaf-mould, broken mortar rubble and silver sand added, into which the large seeds are pressed about ½in. deep. Some of the seeds will germinate the following April, and these can be potted up, grown on for a few weeks and then planted out in their flowering quarters. But the seed bed should not be scrapped, just kept free from weeds and left for another year, as more seeds will germinate in the succeeding April.

J. L. GIBSON.

FLOWERING SHRUBS for HOUSE DECORATION

ALTHOUGH flowers suitable for interior decoration are by no means scarce at this season of the year, there is, nevertheless, an additional charm to the display afforded indoors if the material utilised for filling the vases or bowls shows some originality in the arrangement, or in the flowers made use of, and for this reason—or it may be simply to avoid interfering with the beauty of the flower beds or borders—many people turn to the flowering shrubs to supply their needs in this direction.

Fortunately, there are a large number of flowering shrubs which may be employed for this purpose with the most pleasing results, and it will be readily understood that those mentioned here by no means exhaust the list, but are simply a few examples selected as being suitable for use for interior decoration.



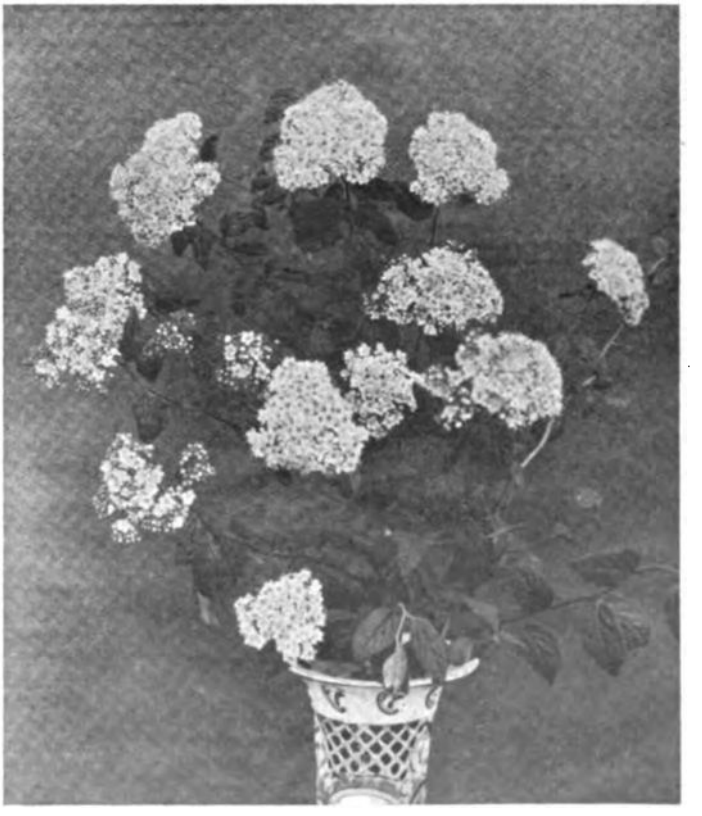
SPRAYS OF THE GLORIOUS YELLOW BLOSSOMS OF ROSA HUGONIS LOOK MOST EFFECTIVE IN VASES.

Often grown and sold specially for this purpose, the flowers of many species of spiræas, such as the one illustrated on this page, lend themselves admirably for use in vases, as also do the flowers of the philadelphus or mock oranges and the deutzias. Garden roses are always popular, and although these are largely used and unrivalled for filling bowls, this by no means disposes of this family, as anyone will agree who has seen a vase of the beautiful Rosa Hugonis with its graceful foliage and bright yellow flowers or of R. Moyesii, which differs only from it in that it has deep red flowers instead of yellow, and few shrubs can excel or equal Moyesii in the autumn, when its flowers are replaced by gorgeous coloured fruits. Very similar to these two Chinese roses is the old Austrian Copper Briar, and suitable for using in the same manner.

Not quite so graceful as the preceding, but nevertheless pleasing in their appearance, the flowers of the weigelas are effective indoors, and the various colours in which these may be obtained gives them additional charm. Provided they are not used too lavishly, the flowers of many of the hybrid rhododendrons look well arranged in a large bowl, especially if the room in which they are displayed is a fairly large one.

Not, perhaps, very lasting, but striking always, the azaleas please not only by reason of their vivid colouring, but by their delicious perfume as well. This, of course, is not particularly desirable throughout the house, but a small bowl of Azalea pontica placed in a large airy hall will be a joy to all. W. H.

SPRAYS OF MANY SHRUBS SUCH AS THE WEIGELAS CAN BE USED TO ADVANTAGE FOR INDOOR DECORATION.



THE FEATHERY TRUSSES OF ONE OF THE SHRUBBY SPIRÆAS ARE LIGHT AND GRACEFUL IN APPEARANCE.

THE BUSY MAN'S PAGE

Removing Suckers from Roses.

THE question of removing suckers from roses may appear to be a very simple matter, but there are many who, through want of experience, know little or nothing about this apparently trifling detail of culture. Before anyone can appreciate what to do in this matter, it is well for them to understand that the whole question is one of stocks. Probably 90 per cent. of the roses grown to-day are worked on one stock or another; only a very small proportion being on their own roots.

The process of raising roses on their own roots is a comparatively slow one, and it would take at least four years to make a good plant; and, again, a goodly number of the better sorts do not possess the essential inherent strength when grown in this manner. Since the plants are not grown on their own roots, many roses develop undesirable suckers, which must be got rid of if the plants are to continue in good health and condition. In order that the beginner may distinguish the stock from the garden rose, a shoot severed from a briar and a shoot from a garden rose are shown below. The latter is figured on the left and the briar on the right of the picture. A careful comparison should be made of these two growths. Stock of the Manetti is not unlike that of the briar; it has tender, pale green foliage and seven leaflets, as a rule. Young sucker growths are of a reddish brown colour, and have thorns of a similar colour. These thorns, or prickles, are composed of large and small ones, the large ones being disposed about an inch apart and the smaller ones in between. The De la Grifferaie stock also favours the rose in appearance, and has five leaflets like the garden rose. To distinguish the suckers, however, the beginner will observe their downy appearance; the young growth is quite mealy-looking and purplish green in colour; the thorns or spines are large and strong, and the bark is red. The second illustration shows a sucker growth that has evolved on a polyantha rose. The extraordinary vigour of these suckers often seriously affects the growth of the plants, unless they are removed promptly. It is useless to cut off the suckers just level with the ground; they must be detached quite close to the roots from whence they spring.

A ROSE BUSH WITH A STRONG SUCKER WHICH SHOULD BE REMOVED.

Summer Treatment of Violets.

THE measure of success with these depends largely on the treatment the plants receive during the heat and drought of summer. If allowed to suffer through lack of moisture, red spider will assuredly appear and the plants become stunted through their vitality being undermined by this prevalent pest. In light soils, copious supplies of water will be needed, though the labour of watering may be much reduced by mulching with litter or lawn mowings or whatever else of a suitable nature may be at hand. In the absence of a mulch, hoeing will do much to preserve moisture in the soil and promote growth. Endeavour to keep the surface soil in a loose, friable condition. Weak liquid manure or a sprinkling of compound fertiliser at intervals of a fortnight or so will further assist in the same direction. The removal of runners as they appear should be persevered with, so that the energy of the plants may be devoted solely to building up strong crowns for future flower production. In the enjoyment of the beauty and fragrance of summer-flowering plants there is the danger of forgetting to attend to practical details which make it possible to enjoy those qualities when the pageant of summer has become a memory.

ON THE LEFT IS A SHOOT OF A CULTIVATED ROSE. ON THE RIGHT THE SHOOT OF A BRIAR.

Cutting Back Aubrietias

THE aubrietia tufts tend to grow loose and untidy during the late summer, and, in time, they become so unsightly that something desperate has to be done to tone up the co ner in which they are grown. After flowering however, they may be clipped back, and clipped back fairly hard, with the garden shears; this does not kill them, by any means, but simply results in a compact mass of shoots springing up in time and the tufts look pretty and neat, almost exactly the same size as before. Of course, they are not pretty just after the garden shears ha'e been at work, but that soon passes and the tufts become a crown of green. The plan has much in its favour, in addition to the point of tidiness, when the garden is limited and the most has to be made of space. The tufts do not encroach on other plants near at hand after clipping, and they are kept a reasonable size. A little sifted old manure may be worked in round the tufts after clipping, if thought necessary; the clippings of named varieties may also be rooted as cuttings in a shady, sandy corner. We may add that clipped plants almost invariably give the finest blossom.

Common Vegetable Diseases.

Celery Leaf Blight.—This fungus causes pale spots on the foliage of celery plants, which then fail to grow and slowly die. Burn badly infested leaves and spray with Bordeaux mixture.

Club Root.—All the brassicæ, and wallflower, stocks and cress may be infested. Growth is slow and sickly; when the plants are pulled up it is found that the roots are clubbed and deformed. There is no cure; burn infested plants and lime the soil heavily.

Onion Diseases.—The plants turn yellow first. Smut is a black mould on the leaves. Burn badly infested plants and dust others with lime and sulphur mixed.

Pea Mildew.—This turns the leaves yellow, then covers them with mildew. Spray with liver of sulphur and feed the plants.

Potato Black Leg.—Potato haulm becomes black at soil level, growth is stunted and tubers small. Burn the haulm; use the tubers at once; do not save them for seed.

Potato Blight.—This is the common potato disease, virulent in warm, damp summers. Leaves first turn brown, then they curl up and rapidly decay. Spray at once with Bordeaux mixture.

Potato Leaf Curl—The name aptly describes the disease. Pull up the leaves and stems, then burn them. Use the tubers and do not save any for seed.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

New Gardens.

THOSE who take possession of a garden for the first time—especially on new housing estates—will welcome a few hints on the initial work that is necessary. In the first place I should advise all beginners to proceed slowly. Make your plan first. This will, of course, depend on your own individual taste and on your household's requirements. If you anticipate using your garden as an outdoor living-room you will require to make a lawn. If the garden is big enough, devote a part to fruit and vegetable growing. To keep off winds and to shut out prying eyes you will need screens which you can cover with pretty climbing plants. In a single season you could cover an archway or trellis with climbing knotweed.

Dig New Gardens Now.

No time should be lost in turning over the soil of a new garden. First mark out the position of paths, and then dig over the remainder, burying all weeds, rubbish, stones, bricks, cans, etc., about 2ft. deep. This ensures good drainage. September is the time to sow seeds for a lawn, but you can begin now to dig over the ground, leaving the stones below and sifting the top soil to a depth of about 3ins. In the vegetable patch you can immediately plant winter greens—cabbage, broccoli and kale—and, of course, salads can be sown.

The Front Garden.

I hope you will not leave your front garden neglected and unkempt while your back garden is made beautiful. I have found that many people do this, arguing that children pluck the flowers in front. I do not think this difficulty is insurmountable. If every front garden were cultivated, I do not think they would be such a temptation to youngsters, and certainly it would make a surprising difference to some of our streets. If you are digging your flower border now, you can make it immediately beautiful by purchasing some bedding plants. These will be followed in autumn by bulbs, and it is not too early to make out your bulb order now. Perennial plants, and trees of all kinds, also such creepers as the self-clinging Virginian creeper (Ampelopsis Veitchii), clematis and climbing roses should be purchased in the autumn.

Looking Ahead.

CARNATIONS, roses, lilies, poppies, cornflowers, geraniums—all are ablaze in the garden. At no season do we find a greater profusion of colour in the border. Here is the result of our labour. Our planning and planting are put to the test during these few weeks of midsummer splendour. We take our chairs on the lawn and sit back and admire. But only for a short time. Garden chairs, be they never so comfortable, must not entice the gardener into forgetfulness of his duties, and even now next year's flowers must be prepared.

Perennials from Seed.—A glance at our own and our neighbours' gardens gives us ideas as to the kind of plants which may advantageously be added to our stock. It is undoubtedly easier to propagate by division of roots, or to purchase plants from a nurseryman; but the cheapness, as well as the added interest, of home-raised seedlings makes a strong appeal. Seeds of pansies, Brompton stocks, polyanthus and campanulas can all be raised easily if sown now in pans or shallow boxes and pricked out as soon as they are large enough to handle. A cold frame is good for wintering such seedlings, but it is not absolutely necessary, and in fairly sheltered gardens most hardy perennials can be raised and left outside all the winter.

Shrubs to Prune After Flowering.

A NUMBER of flowering shrubs, such as deutzia, mock orange, kerria, ribes, Berberis stenophylla, broom and lilacs, bear their blossoms on last year's growths. Now is the best time to prune these so as to promote the formation of sturdy shoots for next season. Cut them well back, especially if they are too large for the space allotted to them, and thin out weakly crowded branches. The best tool for pruning is a sharp pair of secateurs, which can be obtained in several sizes and forms from any horticultural sundriesman.

It is a great mistake to cut beautiful flowering shrubs into balloon shapes with shears. Pruning should assist Nature in her artistry. Flowering shrubs should be allowed to develop a natural effect, and not to become mutilated geometrical monstrosities. Recently I saw a lilac bush, probably ten years old, flowering for the first time. For years it had been clipped as a hedge, and only a fortunate lapse on the part of the owner had given it a chance to display its beauty. (He admitted afterwards that he had always thought it was a privet!)

THE IRIS IS AN EXCELLENT PLANT FOR THE TOWN GARDEN.
The roots can be planted from now on until the end of September. They look particularly well if given a position in the mixed border.

Treatment of Loganberries Now.

THE best of all fruits for the town garden is the loganberry. In the heart of the City there are plants which show, at this season, some fine crops. Small gardens can accommodate them as well as large ones, in spite of their enormous growths, for they can be formed into a screen between two gardens, or can be used in the place of roses to climb over arches and sheds.

Just now the loganberries are doing double work. They are flowering freely, and the fruit as it sets requires extra nourishment. In addition the plants are sending up young shoots from the base. These young shoots will be the ones on which next season's crop is borne. To secure the best results, therefore, loganberries should be well fed at this season. Give a thorough soaking of water first if the soil is dry; then give a liberal supply of liquid manure. This should be made by soaking animal manure in water; but if such manure is unobtainable, fertilisers can be used instead. In the latter event, apply the fertiliser and then water it well into the soil. Follow up this treatment by putting a surface mulch round the base of each plant. Decayed horse manure, leaves, grass clippings, hop manure or any similar material can be used for the surface mulch, the object of which is to assist the soil to retain moisture, for loganberries are gross feeders, and very soon exhaust moisture in the soil.

The other important thing to do with loganberries just now is to keep the young shoots tied in, to prevent breaking. These shoots should be thick and sturdy from the time they show themselves; if they are not, it shows that the plants need more nourishment. But even the strongest shoots are brittle while they are young, and will easily get broken, so that they should be tied in to the supports as they grow. If there is little room to tie them on the permanent support, put in a few stakes and tie them temporarily to these. When the fruits have been gathered, the old stems will be cut right away, and only the new stems will be tied up for next season. Several pounds of loganberries are produced on a single plant, and these make a welcome addition to the family larder, as well as being ornamental in the garden.

How to Obtain Fine Tomatoes.

TOMATOES, whether grown outside or in the greenhouse, need almost daily attention at this growing season, for they will only fruit well if their growth is confined to the single main stem. All side shoots appearing in the axils of the leaves should be removed. This throws the strength of the plants into the flowers and fruits. Leaves which overshadow green fruits should be half cut back to allow the sun to reach them. Tap the stem of each plant with a cane occasionally, as this helps to disperse the pollen, so that the fruit can "set."

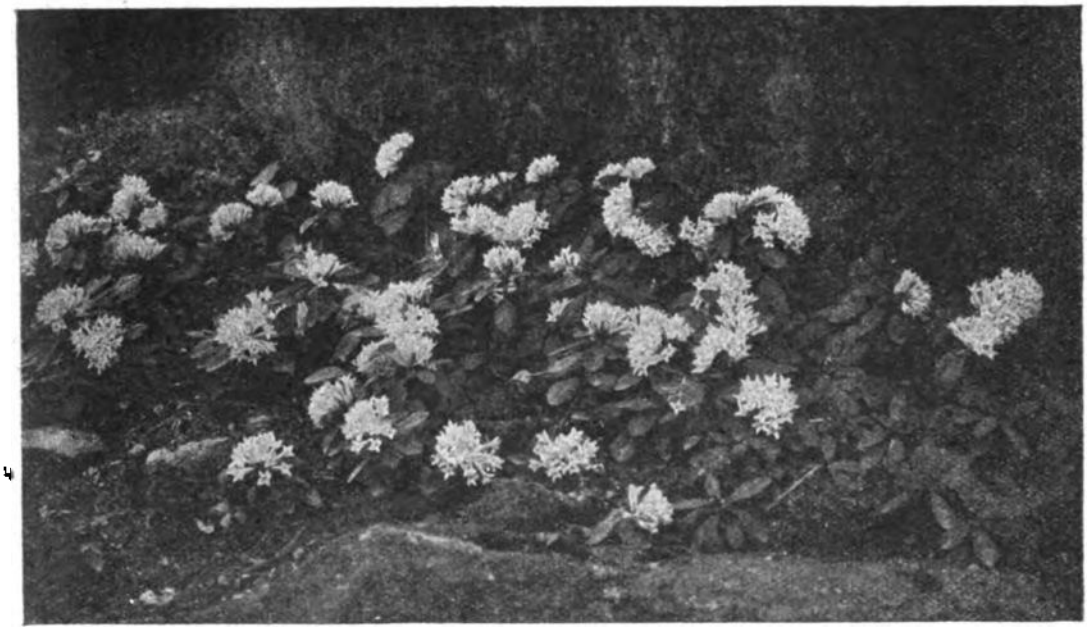
NOTES ON THE FLOWER GARDEN

Daphnes for the Rock Garden.

A FEW fine clumps of the sweet scented daphnes is the delight of all rock garden lovers, and there are at least two species which readily respond to ordinary cultivation. The first to call for notice is the creamy-white and exquisitely fragrant D. Blagayana, a charming species from the mountains of eastern Europe, from whence it was introduced about 1875. It is a dwarf evergreen shrub with a spreading habit, and one of the secrets of successful cultivation is the pegging down of the shoots directly they are of sufficient length for that purpose. Roots are eventually formed and by this means the plant appears to renew its vigour, thereby increasing in size and beauty. Some growers place stones here and there over the growths, this plan also has the advantage of keeping the soil more or less moist during the hot weather. A warm, sunny corner will suit it, although it will succeed in partial shade.



DAPHNE BLAGAYANA, A FRAGRANT PROSTRATE SHRUB FOR THE ROCK GARDEN.

In the illustration can be seen a plant growing on a slope of a rock garden, but it will also thrive on the flat or on a mound with rough stones freely interspersed among the growths. The rooting medium consists of peat and loam, with a liberal sprinkling of sharp sand and it is a good plan to carry out a little top-dressing when pegging down the shoots. The crowded heads of creamy-white flowers appear in March and April, after which the plant makes its growth. If we experience a dry spell of weather while the plants are active, a good soaking of rain-water should be given. I have on several occasions increased D. Blagayana from cuttings in August, but a more reliable method is by layers. For some years the late Mr. Reginald Farrer exhibited well flowered examples of D. petræa (syn. D. rupestris), its rich glowing pink flowers being greatly admired. It is one of the choicest shrublets for the rock garden, also it is somewhat rare and expensive.

Happily there is another species, *viz.*, D. Cneorum, a native of central and southern Europe, which comes a good second to D. petræa, and owing to the ease with which it can be grown, it is a general favourite for the rock garden. It is a beautiful dwarf shrub, about nine inches high, and specimens several feet across are covered with heads of rich rosy pink fragrant flowers in May and June. This daphne enjoys a well drained position, for preference on a slightly elevated situation in the rock garden, with a mixture of loam, peat and old mortar rubble, in which it will revel. In some gardens this exquisite plant will flourish in the ordinary soil, and once I saw it used as an edging to the ordinary flower border. There appears to be several forms in commerce, and when possible the variety grandiflora should be procured. This daphne can be increased by cuttings during July and August, and they readily form roots in a cold frame. The following spring they can be planted in a colony a few inches apart, and in a year or two there will be a patch worth seeing. Another species rarely seen is D. retusa, with pink and lilac flowers, similar to the well known D. indica. It was introduced by J. Veitch and Son from western China, and I saw it in flower in their Coombe Wood nursery about 1909. Apparently it has not proved very amenable to cultivation, otherwise it would be more freely quoted and less expensive.—T. W. B.

A Free-flowering Dwarf Shrub.

Deutzia Wilsoni.

THIS desirable deutzia is a native of central China, from whence it was introduced by J. Veitch and Sons, and it first flowered at their Coombe Wood nursery in 1905. Since then it has found its way into many gardens, and a well flowered example is a fine sight in the early part of June. It is a vigorous shrub some 5ft. to 6ft. in height, and the individual blooms are among the largest in the genus. These are pure white, and are produced in erect thyrsoid panicles, the long arching shoots being covered with bloom. The dark, dull green leaves are about 4ins. in length and an inch or so in width, the branches becoming dark reddish brown as they mature; while the peeling of the bark is an interesting feature of this fine shrub. The plants under notice began to blossom when quite small, and, so far, have never failed to produce a good crop of flowers every June. It will thrive in any good garden soil and, beyond the removal of an old growth occasionally after flowering, little pruning seems necessary. Like most other deutzias, it is easily increased by cuttings, if partially ripened shoots are chosen early in July.—B.

Sow Pentstemon this Month.

IT is worth noting that pentstemons sown in July will, when planted out next year, flower at least a month in advance of those raised under glass in the spring. The method is extremely simple and is specially suited to those who do not possess anything in the way of a heated greenhouse. The seeds should be sown in boxes of light soil, which are best placed in a cold frame. The little plants come up quickly and, when large enough to handle, should be pricked off from 1in. to 1½ins. apart. During the winter the plants are happiest with the protection of a cold frame or some position might be found for them in an unheated greenhouse or a conservatory where they could be shielded from severe frost. Propagation of pentstemons by cuttings is also worth carrying out in the case of varieties which, in the border, have proved to be really fine. Use sturdy side growths and, in September, place these in a cold frame or under hand lights in a sheltered border. The soil should be light and sandy, and the cuttings might be set about 2ins. apart. They will require protection throughout the winter and may be removed to their permanent quarters in April. Although pentstemons are perennial in habit, it is much better to raise fresh plants either by seeds or cuttings annually. One great advantage of the pentstemon is the length of time for which it will remain in flower. Quite often, specimens which started flowering in early June will still be objects of beauty in November. To maintain a display it is an excellent plan to remove the central spike as soon as the best of the flowers are over. Then the production of side growths will be encouraged and each of these will flower with freedom. In dry weather copious supplies of water and occasional applications of liquid manure will be very helpful to pentstemons. In an exceptionally well drained and sunny border it is often worth while leaving a few plants of pentstemon. These may manage to get through the winter fairly well and, if they do, will flower with great freedom in the following season. Even if the subjects are not killed by actual frost, there is always a risk that they may suffer badly from continued wet weather and thus, as has been indicated, it is wise to raise most of the plants annually.—L.

The Madonna Lily.

Why It Sometimes Fails.

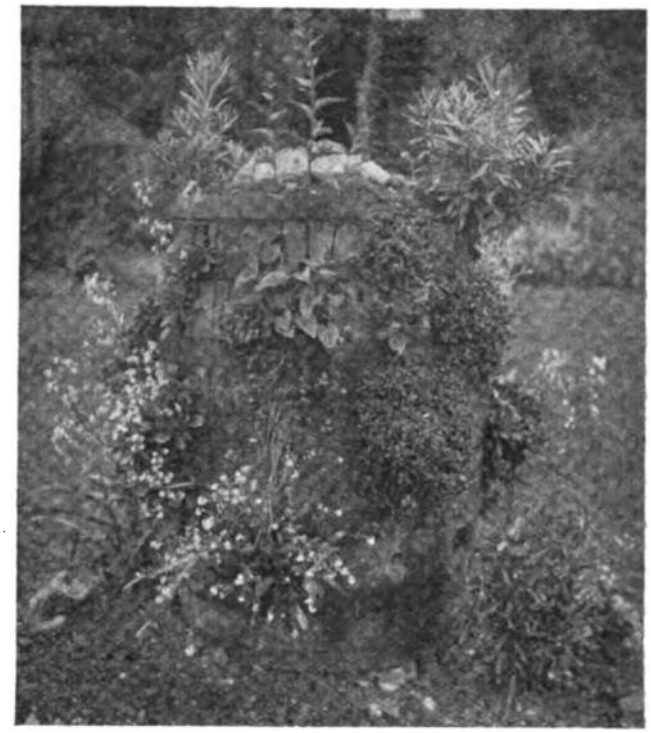
AMONG lilies that bloom in the garden and come to their beauty stage in July, few are more popular or so welcome as the old variety candidum. In many places throughout the country it grows with remarkable freedom, and seldom fails to give a good account of itself. But failures do sometimes occur, and my experience prompts me in saying that they date not infrequently from the very commencement of planting. It is not so much the question of soil, as they will grow equally well in soil of light,

Digitized by Google

sandy texture or in heavier soil, provided there is sufficient drainage to permit of the free passing away of water. What does matter is the *time* bulbs are planted. They are best secured when they are plumpest, before they have had time to send up new growth. Early September is an ideal period, and by October it is wisest to get them in. It is little use planting them in spring, as they are much longer in getting established, and until this occurs flowers cannot be expected. L. candidum is one of those lilies that, when doing well, ought never to be disturbed. In selecting a spot for planting bulbs, preference should be given to the sunniest and best drained. The soil should be trenched or, at least, well dug, and in the bottom spit some old manure worked. Bulbs should be planted a foot apart and 3ins. deep. Manure should not come in immediate contact with them. Amateur gardeners do not appreciate the importance of obtaining new bulbs as soon as they are offered for sale in early autumn, before they have had time to become shrivelled or to push up much growth. Early planting means early root growth and, consequently, less likelihood of failure.—W. F.

Grey Foliage in Garden Effects.

SOMETHING has been said of late in the pages of THE GARDEN about the value of bold plantings of grey foliage as a setting to flowers of purple, pink and white colouring, and its advantage is so striking in places where it has been carefully planned and successfully carried out, that an insistence on its importance may well be repeated. The accompanying illustration shows one end of a garden region where what are called bedding plants are used in the modern or common-sense way, in distinction to the old or less intelligent method. Here are geraniums, calceolarias, dahlias, cannas, gladioli, etc., but placed, not in the dull old way in set edgings or rings or stiff beds, with the colours harshly clashing, but in generous groups and drifts and inter-groupings, with an intention of harmonious colouring. The subject of the picture is when the most gorgeous portion of red and other strong colours has given way to tender colouring. In the immediate foreground is the warm whitish variegated mint, with the pale canary coloured Calceolaria amplexicaulis backed by yellow snapdragons, but all the farther end has masses of grey and glaucous foliage. For the larger plants there are yuccas, phormium and Senecio Greyii, and in the middle spaces Cineraria maritima, and to the front Artemisia Stelleriana, cerastium and othonnopsis. With these there are interplantings of ivy geranium Mme. Crousse, pink carnations, heliotrope, platycodon and Campanula carpatica, with a general front filling of sweet alyssum. The garden narrows to the end of the picture and is closed in by laurustinus. —G. J.



AN OLD BARREL PLANTED WITH HARDY FLOWERS.
This will make an attractive feature for the centre of the lawn or for a roof garden.

Growing Plants in Barrels.

IT is surprising how few people with limited garden space avail themselves of this compact and attractive form of cultivation. Possibly the chief reason is that it is not well known. As an aid to beautifying back yards, roof gardens and odd corners, it is hard to beat. Any disused barrel or tub may be used, even apple barrels suit the purpose. The first thing is to remove or clench all projecting nails around the top. Then up-end the barrel and bore several small holes for drainage. The next thing to do is the boring of the holes for the young plants, starting in rows about 6ins. apart, the same distance between each hole, arranging them diagonally. They could, if so desired, be arranged in triangles or other forms. The diameter of the holes should be just over an inch. The holes completed it is a good plan to paint the exterior, also to apply some preservative inside, as it considerably prolongs the life of the barrel, besides improving its appearance. Planting may begin, as soon as the paint is dry, with the usual method of placing a layer of crocks at the bottom followed with a layer of upturned turves and proceed by adding soil until the first row of holes is reached, or almost. Presuming that the young plants have been carefully selected, and raised from their well soaked seed bed, and having a good ball of soil attached, the success of the enterprise is well-nigh assured. It is best to gather the tender leaves together with the thumb and two first fingers, the roots resting in the palm of the hand, then carefully steer from inside until the crown of the plant is about level with the exterior. More soil should now be added and pressed firmly over the roots. Continue in this manner until all the holes are planted. To facilitate drainage and the watering of plants in the lower part of the barrel, insert a stout stick when nearly half way up. This will be found important. Plants of a taller sort may be planted on top.

The last of these barrels I had contained a row of nasturtiums at the bottom, then strawberries, and on top sweet peas. Standing on a pedestal, with the nasturtiums hanging down in full bloom of varied colours, the ripe strawberries among the green leaves, and the sweet peas in bloom above, the combined effect produced a most fascinating picture. —G. S. T.

A BORDER CAREFULLY PLANTED TO BRING OUT THE FULL EFFECT OF BOLD GROUPS OF FOLIAGE AND FLOWERS.

A Handsome Hardy Climber.

THE Dutchman's Pipe, correctly known as Aristolochia Sipho, is a very handsome hardy climber. The flowers, although of a singular shape, are comparatively small, and the Dutchman's Pipe is chiefly grown for the sake of its large handsome leaves. Mostly the species is employed on walls, but it is really seen to better advantage when used for covering trellis, or for rambling up trees or over stumps. A. tomentosa is smaller in its foliage, but the leaves are a very distinct tone of green and, on this account, the plant is a most valuable climber. Both these species are of extremely easy culture and will grow in almost any kind of soil, although they naturally do best in ground that is well drained. Newly planted specimens should, in a dry season, be freely watered, and the trouble is amply repaid by an increased vigour of growth. Propagation of the Dutchman's Pipe is carried out by means of cuttings of young shoots about 6ins. long, preferably with a heel of the old wood attached. These should be kept in rather a close atmosphere until rooting takes place. —L. B.

PRESENT WORK WITH SWEET PEAS

How to Ensure a Fine Display of these Gorgeously Coloured Flowers.

THIS is the most interesting time of the whole year for the average sweet pea grower. The work of soil preparation, seed sowing, transplanting, staking, etc., has been completed and although it may not be a case of "resting on one's oars," the hardest part of the work has been accomplished.

Watering and Feeding.

Backward and weakly plants should not be allowed to flower until they have reached from 2½ft. to 3ft. in height. It is best to disbud such plants until vigorous growth commences. At later stages in the flowering period, an occasional disbudding will be found very beneficial, it gives the plants a "rest" and improves the quality of future blooms. Many growers experience some difficulty in obtaining good quality flowers, long stems and large blooms after the first fortnight of blooming. Periodical feeding and watering will not only produce better flowers, but will actually prolong the period during which the plants are in bloom. In no other phase of culture is experience more helpful, for the extent and frequency of feeding and watering must always be a question for the grower's own judgment. So much depends on the nature of one's soil, the weather conditions and the state of the plants themselves. The need for frequent watering can largely be obviated by shallow hoeings, or better still, at this time of the year, by applying a surface mulch of loose horse litter, well decayed manure, spent hops or Wakeley's hop manure round the plants. This surface mulching not only serves to retain the moisture, but keeps the surface roots cool in hot weather. If the soil has been richly and deeply prepared, little or no feeding is necessary, a good watering with soft water once every ten days or fortnight being sufficient to meet the requirements of the plants. In the hands of an experienced grower, artificial fertilisers are excellent, but otherwise, great care should be exercised in applying them, or more harm than good may result. The less use one makes of artificials (within reason), the better will it be for both plants and soil. Only backward plants need nitrogenous stimulants. Sulphate of ammonia is effective if given at the rate of ½oz. to the gallon of water and well watered in, but it should not be used frequently. Nitrate of soda, too, is very quick acting, but not very "safe" in a beginner's hands; ½oz. to 1½ gallons of water is ample, but do not get it (or any other fertiliser), on the foliage.

Sweet peas like most of the potash and phosphate manures, such as phosphate of potash and these are conveniently given in a dry state by dusting them along the rows, not too near the plants, and afterwards watering them in.

Most artificial manure manufacturers and sweet pea specialists offer a compound fertiliser specially made up for sweet peas. When applying such compounds, the grower should always follow the maker's instructions carefully, giving under doses, rather than the opposite.

One of the most efficient and "safe" stimulants of all is the old-fashioned liquid manure, which is made by suspending a bag containing cow or sheep manure and soot (in equal parts) in a tub of water. After this has stood for a few days, dilute the resulting liquid with three or four times its quantity of soft water, well watering the plants after applying the liquid manure, particularly in dry weather. Always remember that over-feeding or over-watering is harmful, it is better to err on the other side. Rarely do plants need feeding until late July and then only at intervals of a week or ten days at the most. Watering may be more frequent, but only when weather and soil conditions permit. It is better to give a good watering once a week, than a sprinkling every day.

Cut off all faded flowers and do not allow seed pods to form, or the flowering period may be curtailed.

Greenfly.

I am convinced that many cases of so-called disease in sweet peas can be directly traced to green fly or aphis, which attack the young, growing shoots or tips of the plants. Every season, too, I have seen flowers which are obviously the result of green fly attacks. Usually they are of a picotee-edged variety, but lavender and other shades also show plainly the results of aphis sucking the sap juices when they are yet tiny buds. This causes the colours to "run" and the flowers to assume a curious mottled, streaky appearance. Yet another crime may be attributed to green fly. Birds sometimes nip off the small flower buds in search of them, and we unjustly blame the birds for what seems to be purely mischievous attacks. The remedy is, of course, to destroy the green fly and this is most effectively accomplished by spraying the plants with some good insecticide, such as "Abol," using a "mist" nozzle and giving the young shoots particular attention. Whichever insecticide is used, it is wise to syringe the plants the day following the application with pure soft water to clean their foliage. Sometimes two or three applications are necessary to destroy all aphis completely. The great point is to syringe as soon as the green fly are noticed, or before they have had time to do serious damage.

Bud Dropping.

Up to the present I have had no reports of bud dropping, no doubt owing to the dry weather, but it may not be out of place to touch upon this point, for the symptoms are somewhat alarming to the beginner. What happens is this; the plants suddenly develop the tendency to drop all (or nearly all) their flower buds before they open, and where there should be normally a beautiful show of bloom, only the bare flower stems remain. Fortunately, this is only a passing phase which disappears as quickly as its causes, leaving the plants none the worse. The most common cause of all is too much moisture in the soil, combined, as a rule, with cold, sunless weather. Badly-drained ground is, of course, conducive to bud dropping, as is also a position shaded by trees or buildings, but normal weather conditions in ninety-nine out of a hundred cases almost immediately restores the plants to their proper "balance." It will be inferred from these remarks that over-watering will produce bud dropping, so, too, will over-feeding.

Shading.

It is only too well known among sweet pea growers that some varieties are not what is termed sunproof. Unfortunately, some of the most beautiful of all are numbered among these, and although improvement has been steadily going on during recent years, we still have no pure orange, orange-scarlet or salmon varieties which do not fade in bright sunlight to a greater or less degree out of doors. When grown under glass, these kinds are superb, and it must be rather disappointing to inexperienced amateurs, who order such varieties as Royal Sovereign, Melba or Mammoth, after seeing an exhibit of under-glass flowers, only to find that they fade in sunshine when growing in their own garden. To prevent this fading of colour, the flowers should be shaded during sunny weather by suspending on wire above the plants some thin material such as butter muslin or tiffany or anything similar which will break the direct sun rays. The material must not be left over the plants permanently or it will adversely affect their growth, but if curtain rings are used, it can be readily drawn over the flowers at intervals, when necessary. Another method is to fix up glass frame lights on wooden supports over the plants, but only keen exhibitors find this rather elaborate precaution worth while. Those who consider the above methods too laborious, should make a point of picking blooms in an early stage, when one flower only is fully open on the stem and opening them in water under glass or indoors. Early in the morning is the best time to cut. For ordinary cut flower purposes, yet another fairly effective method is to plant all varieties which are not sunproof in some part of the garden which is shaded from the sun during part of the day, preferably during midday, but I would point out that it is a serious mistake to plant sweet peas in total shade. Modern varieties which need shading in sunny weather to bring them to perfection include Royal Sovereign, Wizard, Guinea Gold, Barbara, Melba, Gold Crest, George Shawyer, Crusader, Mammoth, Tangerine Improved and May Unwin.

Promising New Varieties.

At the time of writing I have seen several of the novelties which will probably be offered in the autumn, and although all were grown under glass, there are most certainly two or three of unusual merit among them. Sweet pea enthusiasts would do well to make a note of Mrs. A. Searles, the new salmony-cerise, which obtained the highest honours at last year's N.S.P.S. Trials. It was raised by Mr. Damerun and the whole stock, I understand, has been acquired by Messrs. Bolton and Son. I saw it growing last season and not only is the colour excellent, but in size of bloom, length of stem and vigour it leaves nothing to be desired. Perhaps its colour can best be conveyed by likening it to a lighter-toned "Charming," with a glowing suffusion of salmon.

Another attractive new variety is Pinkie, a really new and pleasing shade of pink. It struck me as being a deep china pink, tones deeper than Supreme, its colour deepening slightly towards the edges of the petals. I should not be surprised if it supersedes that old favourite Hebe.

Sunkist is said to be a "sport" from Youth, the premier picotee-edged variety. It has the same huge flowers and long stems as Youth, the same picotee edge of deep pink, but its ground colour is cream instead of white, in other words, it is really a cream ground Youth. This indicates its real worth.

Glorious is yet another deep and rich cerise. We have Charming, Peggy, Coralline and Centaur, all good peas in this colour section, but I think there is room for Glorious. It appeared to be of the same rich orange-cerise tone as Coralline, but I understand its habit of growth is identical with that extra vigorous variety Charming.

Amateur growers will be well advised to carry a note book and pencil with them when visiting floral exhibitions, for the purpose of recording the names of any varieties, new or old, which appeal to them personally. The large trade exhibits are most interesting, they usually include novelties which are to be distributed the following autumn, and, of course, the best of the new and standard kinds. They demonstrate too what wonderful quality flowers can be obtained by clever culture.

WHAT OUR READERS SAY

THE VALUE OF CATMINT.

SIR,—Referring to an article by "C. P." (page 382), may I suggest for the benefit of those who have not a frame or labour to spare that it is not the least necessary to go through the ordinary routine of taking cuttings of catmint and then planting out. Some years ago I asked a gardener in Scotland how he managed to get such beautiful edgings of catmint. The answer was: "Just cut off new growth about 5ins. long in April or May, strip the lower leaves and plant firmly where they are to grow." The result is very respectable plants by August, flowering well, and in the second year, as the illustration shows, one plant will measure 4ft. across. The saving of time is immense, particularly if a long border is required. A little attention in watering and shading may be necessary, but I find the shoots start rooting almost at once in practically any situation. The soil here is a good holding loam. The steps and wall shown in the illustration were built in the winter 1925-26, and the wall is already well clothed, catmint, Saponaria ocymoides, various helianthemums and aubrietia being especially effective.—B. M. B., *Duncote, Northants.*

CATMINT IS RAPID IN GROWTH AND EASILY PROPAGATED, AND IS EXCELLENT FOR GARDEN DECORATION.

A WONDERFUL BULBOUS PLANT.

In Praise of Sparaxis pulcherrima.

SIR,—If I was condemned to have one plant in my garden, and one only, I feel certain my choice would fall on Sparaxis pulcherrima. These are now in full bloom, and for grace and elegance, beauty of bud and flower, I know of nothing that compares with this wonderful bulbous plant.

Why it is not more generally grown passes my comprehension, although I fancy the three main objections are lack of hardiness, difficulty in growing, and expense.

To a large extent Sparaxis pulcherrima is not tender. In 1925 I sent bulbs to a friend at Bath, where they were grown in an exposed position in the open. Most of them flowered in 1926, and the latest report is that, in addition to showing a big increase, all the bulbs carry flower spathes this year, despite the very severe frosts of April last. In 1926 I sent more bulbs to a friend in the Midlands, and I have just heard that about one-third will flower this year, and none shows any ill effect from the early severe weather. S. pulcherrima is not difficult to grow, but is somewhat uncertain in the time it takes to establish itself before flowering. In 1925 I transplanted about 150 bulbs; 80 per cent. of these bloomed in 1926.

In the latter year, I broke up and transplanted further large clumps, and of these only 10 per cent. will bloom in the present season. My wife has a particular plant of her own, and for three years in succession found new homes for it, yet each year it has not failed to bloom! The bulbs really do resent interference and should only be disturbed when clumps have become too large, being then planted out from 6ins. to 9ins. deep in fairly light soil and allowed to remain. Often the grass, although evergreen, will die down on transplanting, but will re-appear the following spring and continue to gain in strength and size. From experience I have found August to be the best month for transplanting, and only when the soil is quite damp.

As regards expense, perhaps mature bulbs of the "wandflower" are a wee bit high-priced (from 6d. to 9d. each), but the beauty of the flower is well worth this. Undoubtedly the best and cheapest way is, when possible, to purchase one-year seedlings, which readily transplant and establish themselves.

There are several shades of colour—white, purple, pink, mauve and a very delicate pure lavender—and the association of S. p. alba with Leptospermum Nichollai on a fairly large scale is a sight not easily forgotten.—P. E. E. C., *Cornwall.*

DISEASES OF THE MADONNA LILY.

SIR,—Your correspondent, "H. J.," in calling attention to disease attacking the bulbs of Lilium candidum and the cure therefor, leaves your readers somewhat in the dark as to which of the numerous diseases to which the lily bulbs are liable affected the clump. No doubt, where fungoid diseases are concerned, the application of flowers of sulphur is often fungicidal; but in the case of Botrytis cinerea it is, I submit, an open question whether the sulphur treatment is adequate. During the winter, I was in correspondence with the Sulphate of Copper Association, with the object of ascertaining whether the research department of this organisation had evolved a cure for botrytis in lilies, as they had done in the case of gooseberries and other plants attacked by this almost epidemic disease.

They recommended a trial of a diluted Burgundy mixture sprayed on the foliage, which, in their opinion, will provide a certain remedy.

If any of your readers have attempted the use of this remedy and prophylactic, their accumulated experience would be of great value.—C. J.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

AMONG the controversial subjects associated with the cultivation of sweet peas, the question of planting still occupies the attention of growers. In general practice, two distinct methods of treating pot-grown seedlings are recognised. One consists of transferring the plant to the prepared trench without disturbing the roots; while the other necessitates the separation of the roots from the potting medium. Adherents of each system are to be found in the ranks of both amateur and professional growers, and the cleavage of opinion is emphasised in the writings of experts. As far back as 1908 the late Mr. Robert Sydenham advised that when planting seedlings a hole should be dug just large enough to put in the contents of each pot and that the roots should be disturbed as little as possible. At a later day support is given to that procedure by Mr. Cuthbertson, who advocates lifting the plants with plenty of soil adhering to the roots. Mr. Horace J. Wright believed in the separation of the plants when more than one were grown in a pot, and, like Mr. Sydenham, he warns growers to avoid the smallest damage being done to the roots. This point is also italicised, as it were, by Mr. Thomas Stevenson, who, as an exponent of the other side, tells his readers to "shake out each plant individually." Mr. Charles W. J. Unwin throws more light on the subject than any of these writers. He does not recommend planting the entire ball of soil without disturbing the roots in any way, for the reason that the potting medium is liable to be a trifle sour, and he likes the roots to make a start in entirely new ground.

Some growers, however, desire to settle the question for themselves by planting their sweet peas on both systems, and thus subject them to a practical test. This experiment was tried this year by Mr. Currie, Barskimming, and the results were an object lesson to the members of the Glasgow and West of Scotland Horticultural Society when they visited the gardens last month. The peas that were planted with the ball of soil were in a much more advanced state of growth than the plants whose roots were shaken out of the earth. On measuring representative plants in each row, I found that the former were from 6ins. to 8ins. taller than the latter, while the haulm presented a stronger appearance. In accounting for this marked difference in the development of the peas, Mr. Currie explained that the seedlings whose roots were not disturbed when transplanted seemed to grow

Digitized by Google

on practically from the day they were put out, whereas the plants shaken out of the soil received a check and did not show signs of growth for ten or twelve days later. The experience of several visitors confirmed the results of the tests, and in particular claim for the system of planting the seedlings without disturbance the advantage of earlier flowering. As the first blooms had been removed as they made their appearance, there was no opportunity for comparing the quality of the flowers. It may be added that the two classes of peas were subjected to the same conditions of culture, being planted in specially prepared soil and grown on the single stem principle in rows alongside each other.

Amateur gardeners might take a hint from nurserymen in the propagation of chrysanthemums on any future occasion when cuttings are scarce. This season trade growers have had their stock plants severely depleted, and in order to make good the losses they have had to make use of the tops which had been pinched off the main shoot. When planted in a sandy compost in a frame or cool greenhouse they make nice plants and, though later in being struck they bloom quite as early as the plants grown from cuttings in the ordinary way.

This is the month when attention should be given to the layering of border carnations. Experts who cultivate their plants in pots in a cold greenhouse are in a favoured position compared with the amateur who prides himself on an outdoor collection, for the varieties that were bedded out in spring have, in many gardens, produced comparatively little "grass," while some of it is insufficiently developed for layering, a condition of things that is generally attributed to the unfavourable weather. But it matters not if the layers are arranged round the edge of the pots indoors or round the carnations in the open, the operating process is the same. A sharp-pointed knife, a trowel, layering pins (or the old-fashioned strong hairpins) are the implements required, and the provision of a quantity of light sandy soil is essential to success, especially when the plants are established in heavy ground. Preparatory work consists of loosening the soil round the plant and covering the surface to a depth of 3ins. with the sandy soil. Next, select the strongest layers and, after removing the bottom leaves until three or four stems are exposed, make a clean cut in the stem, which should extend from immediately below (say) the third joint up as far as the next joint, thus forming a tongue. The growth is then pressed into the fine sandy soil, and when the tongue is covered to the extent of ½in. pin it down securely in that position. Repeat the process until the available stocks round the plant are layered, and then water gently with a fine rose can. On the expiry of four or five weeks, during which time the soil must not be lacking in moisture, the rooting system will be formed, and by the middle of September the layers can be detached from the parent plants and about a week later may be potted up and wintered in a cold frame. ST. MUNGO.

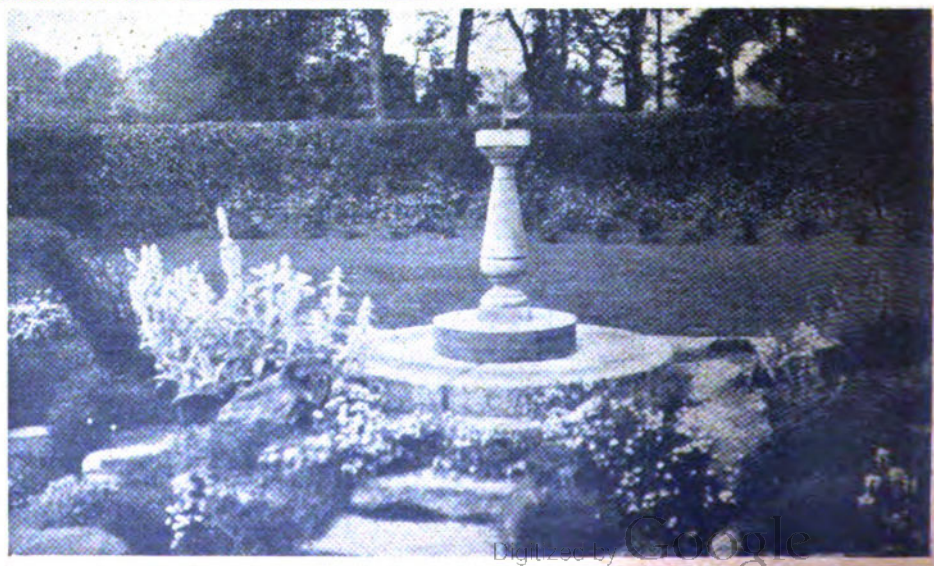
OUR PHOTOGRAPHIC COMPETITION

Masses or clumps of one particular plant always look well in any position in the garden. This week we show how lupins can be used to advantage in this way, and what an effective display they make in the herbaceous border. In the rock garden, likewise, brilliant mats of colour can be obtained by planting one of the alpine phloxes as illustrated in one of our competitors' photographs. Many of our readers must have used other plants in this way and have photographs indicating their usefulness. These will be welcomed to indicate how this idea of mass planting may be extended and to show how many plants there are available for the purpose.

Since the early summer my herbaceous border has made a bright display. A corner of it can be seen in this photograph. Bold clumps of lupins in blues and pinks and herbaceous spiræas, with their light feathery plumes, look particularly well against the background of roses. Ferns and the large-leaved Saxifraga megasea flourish in the half-shade at the end of the border. There are few blanks in the border, as it is always attempted as far as possible to plant subjects which will provide a succession of colour and flower over a long period.

The guinea photograph, sent in by MRS. BAYLEY, 67, *Montpelier Rise, Golders Green, N.W.*11.

This sundial on the rock bank was made from a baluster of St. Enoch's Church, Glasgow, which was recently demolished. The baluster stood on the top of the church for 100 *years in the grime and soot of the city, now it serves another purpose in a purer atmosphere amid the flowers. The base is an old mill stone used for grinding corn* 150 *years ago. It looks very well in its new situation and gives an added attraction to the garden.* ANDREW W. KERR, *Stewarton, Ayrshire.* Award of 5s.



Digitized by Google

These seedling lupins were sown during the summer of 1925. One plant with fawn blooms has thirty-one spikes fully expanded and several are 2ft. long. The colours of the other plants are yellow and mauve, mauve pink, yellow and brown, ruby and shades of pink, and they were planted in this border, which was converted from grass in December, 1926, when it was trenched some 3ft. deep. These lupins have been a joy since the second week in May and as old spikes were cut off they continued blooming for a considerable time. The only secret I know to prolong the display of bloom is to prevent seed from forming. H. W. ROGERS, *Warminster.* Award of 5s.

The flight of rustic steps seen in this photograph forms part of a rock scheme laid down and planted nearly two years ago. The plants include Arabis albida fl. pl., Arenaria balearica, aubrietias of various colours, such as Dr. Mules and Fire King, Lithospermum prostratum Heavenly Blue, Iberis Snowflake and a collection of mossy saxifrages ranging from deep crimson to pure white. MISS S. ROSS, *Renfrewshire, Scotland.* Award of 5s.

This photograph shows a very fine rose grown from seed, the seed being taken from Rosa moschata (the musk rose), growing in the garden of the Manor House, Greatham, Liss, Hants. It is particularly suitable for an arch, being so compact in habit. This rose bears large clusters of white single blossoms, and in the centre of each flower is a cluster of yellow stamens. It is perfectly hardy and most attractive. MR. H. SWYER, *Greatham, Hants.* Award of 5s.

Phlox subulata "Vivid," is one of the best of the alpine phloxes. It is very free flowering and if planted on a ledge in the rock garden, it soon forms thick mats of foliage which bear, during the early summer, numerous salmon-rose blooms. It is of the easiest culture and is an excellent plant for the amateurs' rock garden, providing a rich display of colour over several of the summer months.
V. TREUENFELS, *Damerow, Germany*
Award of 5s.

THE FRUIT AND KITCHEN GARDEN

The Treatment of Melons in Frames and Houses.

WHERE care has been taken to cover frames during cold nights and, also, to ventilate the structures judiciously, the plants have made very good progress, although the weather conditions have been mostly adverse. Midsummer is past, but very often we experience really fine warm weather, very suitable for melons and other tender fruits during July and August. When the fruits of melons begin to ripen, that is, to turn colour and the aroma from them is very pronounced, very little water must be applied and clear water, only. The structure must be ventilated carefully, some air being admitted through the top ventilators all through the night. Of course, cold draughts during dull spells must be avoided. During the last three days or so, place a light covering directly over the ripening fruits if the sun shines brightly, to enable the fruits to finish the ripening gradually, then the flavour will be better. Before the fruits are eaten, place them in a cool cellar or similar room for two days and two nights and turn them over twice each day. In this way the full flavour will be brought out, the flesh being cool and sweet. Where young fruits are just now forming on plants that stage is reached when feeding will be most beneficial. Concentrated manures may be applied according to the directions given with them; also, well diluted farmyard or similar manure. Weekly top-dressings with pure loam in a nice lumpy condition will do a lot of good and, directly each thin layer is applied, water with the liquid manure. As the fruits swell, support those depending from the plants trained under the roof glass with nets and others, growing in frames, should be carefully raised and placed above the foliage on empty, inverted flower pots. While growth is active a moist atmosphere must be maintained.—HANTS.

Seed Tubers of Early Potatoes.

CULTIVATORS who have grown crops two or three years from seed saved from their own gardens should procure seed tubers from a distance, preferably Scotland, for next year's crops, because deterioration will set in if home-saved sets are planted again. It is best to have fresh seed tubers after the second year. Where home-saved tubers are being dealt with now, I strongly advise cultivators to save only those from strong haulmed roots. Do not mind about the skin being easily rubbed off. Leave the tubers exposed to the air on the ground for one hour before gathering them up and, by that time, the skin will be set firm enough for safe handling. Then place the tubers in thin layers in shallow boxes or in a cold frame fully exposed to the sun, but subject to ample ventilation. Turn the tubers over two or three times until all parts of them are greened. From this position transfer them to shallow boxes in single or double layers, place the boxes in cool, dry sheds where plenty of air will reach them, but not direct sunshine, and endeavour to keep them so throughout the winter, only taking due precaution to exclude frost. It is always wise to examine the tubers carefully occasionally for any diseased ones. —CHRISTCHURCH.

Sow Spring Cabbage Now.

WHILE in many districts spring cabbages have only just been cut, it is now time that attention was paid to making a start with those for use in 1928.

The third week of July is none too early for Scotland, and the last week of July or the first week in August for the south of England. A site should be chosen where the ground has not been recently dug, but has been well cultivated on the surface and can therefore be reasonably considered free of surface weeds now and for the future, a very necessary point when we get showers in late August.

A narrow drill is preferred by many, but I prefer a wide, flat and shallow one, which will give each plant space in which to develop. As to varieties, a glance at many catalogues would lead one to believe them legion, but I fasten my faith to a few. For a small early cabbage a good stock of Pioneer as sent out by a few leading seedsmen both sides of the Border requires some beating, although Flower of Spring is very like it. For a larger cabbage I have always failed if I used other than Mein's No. 1 put out by Messrs. Stuart and Mein over seventy years ago. It is the cabbage for bulk plus kitchen qualities *par excellence*.

For those who grow exhibition onions Mein's Monarch is well entitled to be placed alongside No. 1 cabbage, and are both selected and grown for seed in Scotland, and their hardihood is beyond doubt.—S.

Parsley for the Winter.

ALMOST every gardener has his own special ideas as to the best time to sow parsley seed. To keep up a supply of this useful herb throughout the winter, especially during the early months of the year, often proves rather a difficult matter. Here is a plan which has proved to be very successful in the matter of securing a winter supply of parsley. Prepare a bed by deep digging and thorough drainage in some warm sheltered spot such as at the foot of a south wall. The seeds should be sown in drills, which should be opened up in advance and thoroughly soaked with water. The seeds should be covered to a depth of quite half an inch with fine soil which is somewhat inclined to dryness. The thinning should be done before the plants start to spread much, from 3ins. to 6ins. apart being allowed. If the plants show exceptional vigour of growth, more space may be given; but, when picking begins, the specimens are usually kept well within bounds. Mulching between the rows with a little short manure is very helpful, and abundance of moisture should be given if the late summer is hot and dry, as parsley often suffers badly at such times. The plants thus grown will have developed well before the setting in of the winter, and they will then stand free cutting. An additional advantage of sowing in the summer is that few of the plants run up to flower in the following year, and the small number that do can be removed and a good even bed still remains.—S. L.

Raising Sage from Cuttings.

IT quite often happens that well established sage plants which seem likely to go on for many years will suddenly die. Sometimes this is the result of a cold or very wet early spring, but, on occasion, no very clear reason can be discovered. Many gardeners rely on one or two large sage plants, and then, owing to the death of the specimens, may suddenly find themselves without any of the useful herb at all. It is a very excellent rule to raise a few fresh plants from cuttings every two years in order to make sure of having a certain number of young strong plants always on hand. Cuttings or slips of sage, preferably with a heel of old wood attached, will root freely at the present time if dibbled firmly into the ground. Allow 8ins. apart either way and water the cuttings if the weather is dry. Another way of propagating sage is to pull down a few of the woody outer branches of the plant and then peg on to the ground. Cover the part of the branch in contact with the ground with soil which should be kept moist. Rooting soon takes place and the branches may then be severed from the parent plant.

Present Treatment of Onions.

MANY amateurs like to have a bed of large onion bulbs every year. As seasons vary, so, too, must the treatment if the very best results are to be obtained. The large bulbs result from seedlings that are transplanted in April. Rarely have such adverse weather conditions obtained since that date for the growth of onions. The winds have been cold, especially at night; the sun has been, at times, scorching. Watering, in such circumstances, after the initial applications at planting-out time, does more harm than good. Hoeing the soil surface twice weekly has been the most beneficial. Weeds do not grow, moisture in the soil is conserved, and the ground is ventilated and warmed. By far the best policy is to trench the soil deeply and well enrich it with good manure, plant out properly hardened strong seedlings about mid-April, water once or twice, then, beyond the regular hoeing, leave the plants alone. In my own case, last spring I tried a fresh plan. When making some holes for parsnips I also made a row of holes for some onions. The holes were duly filled with a special compost, made firm. Fine dry fowl manure and bone-meal were added. In due course one onion plant was carefully planted in each hole. Present condition of plants two-thirds larger than those growing in the same bed the soil of which was ordinarily deeply dug and manured. A surface mulch or dressing of finely sifted poultry manure and soil mixed, applied in showery weather, will do a lot of good. Failing this, use sulphate of ammonia at the rate of 1 oz. per yard run of row, keeping the powder from the plants. If mildew appears, use a sponge dipped in "Abol," simply wiping off the patch of mildew, not touching any other part of the plant. I have, by using this remedy in good time, saved a large bed of plants from being crippled by the fungus.—G. G.

Turnips and Soil Pests.

THE more dangerous pests which infest turnips are those found attacking the plants in the seedling stage and among the worst is the flea beetle. This little pest is seldom absent from the turnip border, but only in dry seasons and when the culture has not been careful, is it really virulent. Turnip ground ought in all cases to be reduced to a fine tilth before the seeds are sown, for coarse clods are a direct encouragement; the seed should also be sown during moist weather, if possible. Squirting soapy water containing a little paraffin oil along the drill is good, or quassia and nicotine may be used. I find that the best plan, nevertheless, is to water the seedlings with water containing nitrate of soda, 1oz. per gallon; this can safely be sprinkled over and round the plants and the stimulating fertiliser and the water give that impetus required to bring the plants past the seedling stage and so into safety. I also find that nitrate is a distinctly discouraging application against soil pests like leather jackets and wire worms; in addition to rendering the plants nauseous, it again stimulates growth and carries the plants into leafiness and security. Black jacks or leaf-eating maggots succumb readily to almost any pesticide, but I always prefer nicotine when I do have a visit from this enemy.—CLYDESDALE.

THE SUMMER ROSE SHOW

THEY say that "Fortune favours the bold," but fortune, in the guise of the weather, so far from supporting the bold policy of the National Rose Society, played it a scurvy trick on July 1st and 2nd last. For a number of years the great Summer Rose Show of the Society was held at Regent's Park; but reasons, which need not concern us now, induced the council to seek a fresh venue for this most important show. Boldly they fixed on the ample grounds of the Royal Hospital at Chelsea. But the weather was more than unkind. For days before the opening day and in the morning storms prevailed. The tents at Chelsea were flooded and the Show might well have been ruined; but the enterprise which has characterised the National Rose Society prevailed and rose superior to these most depressing conditions.

The effects of the stormy weather were apparent at the Show, for there was an absence of several well known trade growers and amateurs whose blooms had been damaged beyond recognition. In spite of this, the quality of the roses was high, and it was generally difficult to realise that the storm damage to rose blooms was widespread.

As ever, the representative groups of cut roses were a great attraction, and it was a happy accident that placed the table on which Messrs. Alex Dickson and Sons arranged their Championship group in the very centre of the tent. And it was well supported by the handsome groups of Messrs. Chaplin Brothers and Messrs. B. R. Cant and Sons, who were next in order of merit. The general idea of the exhibitors seemed to be an arrangement of pillars and baskets of roses rising above a groundwork of massed vases. If all were of a mind, this would inevitably tend to monotony; but although there was, to a certain extent, a family likeness in many of these exhibits, no two were alike, so that there was a pleasant variety. Although their names did not appear in the prize list, Messrs. Waterer, Sons and Crisp, Mr. Elisha J. Hicks and Mr. J. H. Pemberton set up admirable exhibits in the premier group class. The principal varieties were Shot Silk, Sunstar, Lady Inchiquin, Betty Uprichard, Mrs. Henry Morse, Mrs. Henry Bowles, Mabel Morse, Golden Emblem and Paul's Scarlet Climber.

In the class for a medium-sized group, the first prize was won by Mr. George Prince,

THE DECORATIVE SPRAY VASE OF SHOT SILK WHICH WON THE NICKERSON PRIZE.

and he was followed by Messrs. Walter and Sons and Mr. J. Mattock; while Messrs. Jarman and Co. had the best small group and Mr. George Lilley was second, with Mr. David Long third. In these classes the arrangements were all attractive and similar varieties to those in the large class were used.

There were many good vases of roses in the exhibits which were intended to illustrate the foliage and habit of growth of the varieties. Messrs. Morse Brothers were first with beautiful vases of The Queen Alexandra Rose, Shot Silk, Lady Pirrie, Lord Charlemont, Betty Uprichard and other good garden roses. In his second prize collection, Mr. Frank Spooner showed Mabel Morse, Mme. Butterfly, Gorgeous and Marcia Stanhope

The baskets of roses were not so numerous as usual, but the quality generally was quite good. Mr. Henry Drew was alone with seven baskets, and he showed Mrs. Courtney Page, Lady Inchiquin and Mrs. Henry Morse in good quality. The three baskets were particularly good, and Messrs. A. Warner and Son, the only exhibitor, had Hortulanus Budde, Golden Emblem and Mrs. Henry Morse of high quality. Polyantha roses in baskets made an unexpectedly bright patch of colour, and those of Locarno, Frank Ladds and Golden Salmon, which, shown by Messrs. William Cutbush and Son, were very beautiful. Messrs. Morse Brothers had Rodhatte, Gwyneth Jones and Lady Reading in their second prize exhibit. Mr. Elisha J. Hicks also staged a fine collection in this class. Frau Karl Druschki, shown by Messrs. Jarman and Co., was the best basket of an H.P. variety, and in Mrs. Henry Bowles they also had the best H.T. This latter was a very strong class, and Messrs. George Longley and Son were second with a bright basket of Mrs. Henry Morse. The Brayford Challenge Cup, offered for any variety put into commerce since January 1st, 1921, was won by Messrs. Morse Brothers with a brilliant basket of Shot Silk. Messrs. A. Warner and Son were second with Lady Inchiquin.

Exhibition roses, shown on boards, were of surprisingly good quality in this difficult season. The Championship was won by Messrs. B. R. Cant and Sons, with Messrs. Frank Cant and Co. second and Messrs. G. Longley and Sons third. The principal varieties were Mrs. Courtney Page, Lemon Pillar, Modesty, Robert Hewitt, Mildred Grant, Colcestria, Courage, Lady Inchiquin and Lord Charlemont.

Messrs. Jarman and Co. had a splendid board of twenty-four blooms, including Mrs. E. Hicks, H. V. Machin, Candeur Lyonnaise, Mrs. J. Laing and Edgar M. Burnett.

Tea and noisette roses bore fewer signs of the weather than might have been expected, and Messrs. G. Longley and Sons, who won the first prize, had fresh blooms of Auguste Comte, Hugo Roller and Mme. Hoste. In the second prize exhibit of Mr. Henry Drew there was a very bright bloom of Auguste Comte and the pink F. Von Marshall.

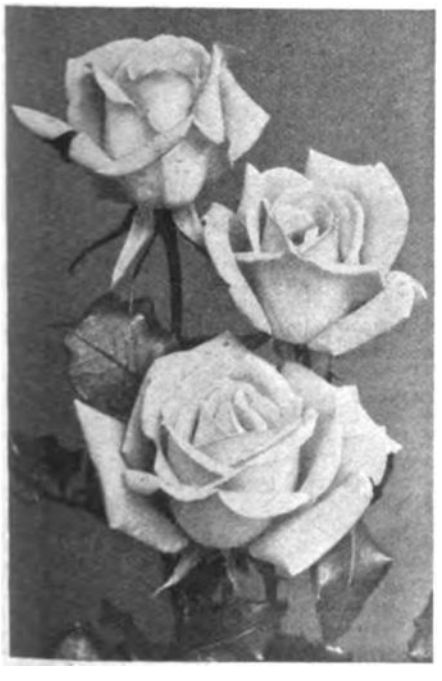
Roses of recent introduction were of only moderate quality. The best were Maud Cuming, Betty Hulton, Gwynne Carr, Clovelly, Mme. Beatty and Mrs. C. Edwards. The first prize winners were Mr. John Mattock and Messrs. B. R. Cant and Sons.

AMATEURS' ROSES.

The amateur rosarians fully held their own in the quality of their blooms. The Championship group of Mr. J. N. Hart of Potters Bar was an admirable display from every point of view, and Mr. H. R. Darlington had a very good smaller representative group.

Their exhibition roses were also very creditable, and Mr. C. H. Rigg, St. Albans, Mr. W. E. Moore Berkhamsted; the Rev. F. R. Burnside, Stanbridge Rectory; Mr. E. W. Turner, Herne Bay; and Mr. A. N. Rogers, all won first prizes with beautiful blooms of similar varieties to those shown in the trade classes.

As usual, the ladies' decorative exhibits filled a large tent and attracted a deal of



ROSE ELIZABETH OF YORK SHOWN BY MESSRS. DOBBIES.

ROSE LADY FORTEVIOT WHICH GAINED A GOLD MEDAL, SHOWN BY MESSRS. B. R. CANT AND SONS.

Digitized by Google

attention. In the open class the best dinner-table was arranged by Mrs. A. Tisdall, who used Richmond to good effect; and Mrs. L. R. May was second. Mrs. Tisdall, who associated Richmond with Edith Cavell, was first with a basket of roses.

In the amateur classes Mr. Colston Hale was placed first with a dinner-table of Cupid and Irish Elegance in the class for single-flowered varieties; but the flowers did not continue fresh. Mrs. Courtney Page had a charming table of Roselandia in the class where the singles are barred, and she was also first with a vase of roses, showing Mme. Butterfly and a beautiful bowl of mixed varieties. Miss Woolmer was first with a basket of roses and a bowl in the class for members who have never previously won a first prize.

NEW ROSES

Although there were many new seedlings awaiting judgment, only two were found worthy of gold medals, and four certificates of merit were awarded.

Everest.—This handsome white H.T. rose was awarded the certificate of merit at the Society's Summer Show last year, and on the present occasion it received the gold medal. Shown by Messrs. Walter Easlea and Sons.

Lady Forteviot.—This is a beautiful Pernetiana variety. The flowers are very well formed and of rich golden yellow colour flushed with cardinal, becoming paler at maturity. It has a sweet perfume. Gold medal. Shown by Messrs. B. R. Cant and Sons.

Bernice.—A lovely H.T. rose recommended for bedding and exhibition purposes. It is fully double, very pretty in the bud and half-open stages, and of fair fragrance. The colour is yellow, heavily flushed with pink and with a pale gold reverse. Certificate of merit. Shown by Mr. J. H. Pemberton.

Chin-chin.—An uncommon multiflora variety. The flowers are single and the petals are set slightly apart. It is of medium pink colour with a pale gold zone. It is said to be a vigorous variety, growing 20ft. in a season. Certificate of merit. Shown by Messrs. F. Cant and Co.

Elizabeth of York.—A robust H.T. variety recommended for general purposes. The fully double flowers are of good shape and of rich, glowing crimson-cerise colour with a suggestion of gold on the reverse. The petals are broad and recurving. Certificate of merit. Shown by Messrs. Dobbie and Co.

Sunshine.—A very free-flowering dwarf polyantha variety, and said to be of perpetual habit. The flattish, double flowers are about 3ins. across and of orange-apricot colouring. The buds are reddish and the foliage is good. Certificate of merit. Shown by Messrs. W. Cutbush and Son.

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry.*

We have selected the following enquiries with their answers, as being of more general interest, and therefore worthy of publication.

Diseased Lupins.

I enclose sections of the foliage and root of a lupin which is apparently diseased and should be glad of your diagnosis. The plants' leaves began to curl a few weeks ago, and as I noticed the redness of the under side of the leaves I treated it with "Abol" for rust, without any effect. Upon digging up the plant I noticed what seems to be a fungoid growth on the roots and am anxious to stop the spread of the disease. Plants adjacent to this one are quite healthy, with the possible exception of three delphiniums, which show a slight tendency to curling in the leaves. A lupin 4ft. away is in perfect health. If possible I should like to save the delphiniums if they are contaminated. As a precautionary measure I put plenty of garden lime in the place where the lupin has been.—C. A. N., Sheffield.

The lupin is attacked by root-knot eelworm. The large galls—not to be confused with the smaller and natural galls containing nitrifying bacteria—contain numerous parasitic eelworms, Heterodera radicicola. It is essential that all pieces of infected root be removed from the soil and to fork in a good dressing of unslaked or quick lime round about the place from which the plant was removed. Lupins should not be planted in this position for at least two years. It is unlikely that the delphiniums are suffering from the same trouble, but it would be wise to send along material in order that a correct diagnosis may be made.

Plum Trees which Bear no Fruit.

I have two plum trees in my garden, a Golden Gage and Magnum Bonum, which I planted about 1916, in a position on the lawn. They were here about seven years and during that period I got a fair amount of bloom every year, but no fruit. Thinking that it was root pruning which was required, I moved them into the border, about three years ago, but with no better result. Can you advise me as to treatment, or should the tree be destroyed as useless. They appear healthy in every other respect. The soil is somewhat heavy and damp in the winter.—A. W. G. H., Ealing.

There are three possible reasons why your plum trees fail to set fruit, even though blossoming well. The first and most likely reason is that the blossom is not suitably cross-pollinated. If you planted a tree of Victoria or Dennison's Superb near by, you would probably find that when these trees flowered together they would cross-pollinate one another and set reasonable crops. With their own pollen, or with the pollen of each other, the two sorts you are growing are not really fertile, any other pollen must be introduced by planting a tree of another sort near by. The second possible reason is that the soil lacks sufficient lime. Dress the ground about the trees with lime this autumn and repeat the dressing every second or third season if the soil does lack this food. Thirdly, if the trees are exposed or in a draughty corner, then it may be that cold winds prevent the fruit setting. Shelter of some kind, provided by large shelter trees, or netting during blossoming period, erected on the exposed side is the remedy for this. Finally, remember that youthful plum trees—up to eight years old—frequently flower well, but seldom crop well. We cannot say definitely why your trees fail from the information contained in your letter, but if the above points are attended to, we think you should get the trees into bearing before long. It seems a pity to scrap such promising trees, especially as they normally carry plenty of bloom.

Making a New Lawn.

I am wanting to convert five large rose beds into a lawn this autumn and I am writing to you for expert advice on the matter. Can I hope to grow a lawn from an autumn sowing and how late in autumn can I sow it with hope of success? My difficulty is that I would like to save my rose trees and I want to leave it to the last moment to lift them. Can rose trees be moved in August or September with safety?—E. L. S., Jersey.

If you can thoroughly prepare the soil for the grass seed by the middle or third week in August, a very good lawn will result if ordinary care be taken. It is rather early to lift and transplant roses, but if they are kept watered in dry weather the trees should live. To have a lawn resultant from seed sown in August or the early part of September, you must be prepared to take some risk.

Dropping of Young Pears and Propagating Young Lilacs.

All my young pears are dropping off. Can you give the reason, as it is a failing common to pears in this district. The pears are young trees, three years espalier and cordon grown on house wall facing east, soil very sandy gravel. These trees have had a little top manure, also lime and are watered well once a week with a hose from stand pipe of water supply. The pears form, then the stem turns yellow, brown at base, and pears drop off when actually quite green. Also, I have a double lilac that I wish to propagate for sentimental reasons. I have tried cuttings without success and it is impossible to get a branch to layer. Could I graft on to a common lilac? If so, please give me full particulars and time to do it? What kind of graft, etc.—I. M. B., Dorset.

We have examined the pear fruit sent for inspection, and find that it is imperfectly fertilised. Possibly, unfavourable weather at blossoming time is responsible for this failing, or, it may be, unsuitable pollination. Many pears are, of course, self-sterile and unless the flowers are cross-pollinated with pollen from a suitable variety, they fail to set fruit in any year, however prolific the bloom. There is certainly no disease of any kind attacking the sample sent and the yellowing of the stem, the browning of the base and premature dropping are typical of what might be expected to happen to an unfertilised fruitlet. They normally swell to the size of the sample sent, even though unfertilised, but develop no further. You should have no difficulty in propagating lilac if you insert cuttings now in sandy soil and cover them with a bell glass. If you have a greenhouse, or cold frame, place the pot and bell glass in this. Grafting is done in early spring on the common lilac. The stem of the small lilac and the 6in. long graft of the double lilac should be the same size.

An Ornamental Hedge.

My garden is divided from my neighbours by a privet hedge, backed by a three strand wire fence and wire netting, the whole about 3ft. high. I wish to replace the privet with something more ornamental. The substitute need not form an impenetrable hedge and is not required as a wind break. It should not exceed 4ft. high, nor take too much nourishment from the soil, and should be moderately thin when clipped or trained. My fancy turns towards berberis. Would you kindly inform me whether that species is suitable for my purpose and recommend varieties for forming a hedge 50ft. long. I presume seventeen plants will be required of mixed varieties.—B. T., Thorpe Bay.

The two evergreen barberries, Berberis stenophylla and B. Darwinii, are the best for hedges. The growths of B. stenophylla are long and slender, arching with rich yellow blossoms in late April and May. B. Darwinii is stiffer and more upright in growth, with rich orange yellow blossoms in April and May. We suggest that you form half the hedge of one and the other half with the other. Being so different in habit they cannot be well planted alternately. Prune each year after flowering to keep the hedge about 4ft. high.

THE WONDERFUL NEW ICELAND POPPY "COONARA"
UNWIN'S SELECTED STRAIN.

THIS beautiful Novelty is undoubtedly one of the best and most valuable introductions of recent years. Its habit and cultural requirements are similar to the Iceland Poppy, but "Coonara" is larger flowered, very "crimped" or waved in the petals, and long stemmed. The colour-photo above gives little idea of the wide range of its exquisite tints, which embrace all shades of pink, salmon-pink, lemon, cerise-pink, tangerine, apricot, old gold, salmon-biscuit, salmony-saffron, orange-scarlet, etc., etc. It is ideal for indoor decorations, very easy to grow, and being quite hardy will withstand the severest winter. Twenty-five plants will furnish a vase of flowers continuously for at least three months. Sow now for best results, and transplant September and October.

SEEDS—1/- per pkt. (about 1,200 seeds). **PLANTS** (ready September to October)—25 for 2/6, 7/6 per 100. Carriage paid

THE GARDEN

VOL. XCI.—No. 2903. JULY 23, 1927. PRICE TWOPENCE

A NEW POPPY

THE new poppy illustrated on our front cover is one of the most interesting and valuable of recent floral introductions, and well worth a trial by all who appreciate a genuine novelty. Its name gives one little idea of what it really is: Coonara Pink was introduced by an Australian firm. It is said to have been raised by a lady from a cross between the single Iceland and the Shirley poppy. In habit and form of flower, it is practically identical with the single Iceland, though its flowers are, on the whole, larger and the petals prettily frilled or crimped. Some of the shades found in Coonara are, perhaps, faintly reminiscent of the Shirley, but there the resemblance with the latter ceases. Evidently it was introduced in the belief that it would come fairly true to colour, otherwise there would be no point in its name. We saw, a few weeks ago, a fine bed of many hundred plants in full bloom at Messrs. W. J. Unwin's nursery at Histon, but not more than 25 per cent. at the most could be classified as any shade of pink; indeed, no two on the whole bed seemed to be exactly alike in shade. This unfixity is an advantage rather than otherwise, for the colour range is remarkably wide and pleasing. If the pink, or any others of the exquisite shades, can be "fixed" so well and good; but in my opinion, Coonara Pink is certain to please a much greater number of amateur growers as it is. It is impossible to convey an accurate impression of the wonderful tones, nearly all of them self colours. They embrace all shades of pink, salmon, lemon, tangerine, cerise-pink, apricot, biscuit, saffron, old gold, salmon pink, yellow, orange, etc., strongly reminding one of those soft and dainty shades as well as the bright colours found in begonias. In spite of their diversity of colour, there is no sign of "clashing" when they are mixed together, only a warm and attractive blending.

Iceland poppies are favourite cut flowers for indoor decoration, but these new hybrids will be found much more valuable for this purpose. All flower lovers will want them on account of their charming colourings, dainty and graceful form, and easy culture. The recent exhibits of Messrs. W. J. Unwin at the R.H.S. Hall (entirely of Coonara), have created no small amount of interest and favourable comment.

For cut bloom, Coonara, like the Iceland poppy, should be picked when young, just as they are opening, and preferably in the early morning. Should any difficulty be experienced in making them "hold up" in water, it is a good plan to insert the ends of their stems in boiling water for a few seconds; indeed, this procedure is usually necessary in hot, dry weather. If cut in the young stage, the flowers have excellent lasting qualities; but to obtain the maximum effect they should be arranged lightly and daintily in slender clear glass vases. Much of their beauty and all gracefulness is lost if the vases are overcrowded. The light, feathery wild grasses, such as one finds along any ditch or hedgerow, are all that is needed in the way of foliage. We received from Messrs. Unwins a box of blooms, and although the flowers were wilted on arrival, they responded well to treatment in hot water. They look particularly well in a vase in our office and they remain in fine condition although received about a week ago. It is certain to become a popular plant once its merits as a cut flower for house decoration are realised.

Their culture is very simple. Although, strictly speaking, they are hardy perennials, they may be sown in boxes in the early spring and will bloom the same year. Better results however, may be obtained by treating them as hardy biennials. Prepare the seed-bed now, leaving the soil in a fine condition. Sow the seed thinly (it is very tiny indeed) in drills, at the end of July, watering the drills before sowing if the soil is dry. As a rule, no further watering is necessary; but should a dry spell set in when the seedlings are small, water them periodically as they need it. At the end of September or early October, transplant them firmly to their flowering positions, choosing a time when the soil is nicely moist. They are more effective when planted in a bed by themselves than when dotted about here and there in the border; but in either case, prepare the soil deeply and manure it liberally, for, like the Icelands, these poppies will "stand" a good deal of feeding, and good culture will be amply rewarded by greater length of stem and larger flowers. Bone meal will be found an excellent fertiliser if incorporated in the soil just before transplanting. A few plants may bloom in the late autumn, but this should not be permitted. If the buds are nipped off when small it will give the plants greater strength. They will flower profusely and continuously from May onwards if the blooms are picked regularly and no seed pods allowed to form. They are like sweet peas in that one can "cut and come again" every day for weeks.

This Week's Work

For Gardens in the South and Midlands.

Prepare beds for planting irises.

Spray potatoes with Bordeaux mixture to guard against potato blight.

Transplant into open ground seedling biennials.

Water border carnations which have been layered.

Lift early potatoes and winter onions.

Keep rambler roses tied to trellis-work.

Plant out leeks for a winter supply.

Sow spinach for autumn and winter pulling, and dust carrots with soot and lime to ward off carrot fly.

This Week's Work

For Gardens in Scotland and the North.

Sow herbaceous calceolarias.

Spray maincrop potatoes.

Sow myosotis for spring flowering.

Protect heads of cauliflower by bending leaves inwards.

Sow pansies and violas.

Propagate hydrangeas, fuchsias and spiræas by cuttings.

Remove spent blooms of Canterbury bells to induce later flowering.

Divide and pot up spring flowering saxifragas.

Plant meadow saffrons and autumn crocus.

Trim ragged edgings of catmint, arabis and aubrietia.

Pot on cyclamen.

LILIES FOR EVERY GARDEN—I

Many amateurs imagine that lilies are difficult plants to grow. Such is not the case. Provided a little care and attention are given when and after planting, there is no reason why they should not be successful. A few prefer a limy soil. Others do not, and will grow readily in a moderately heavy loam. All the necessary hints for successful cultivation are given in this article, together with a list and description of species which the amateur will find it worth his while to plant this coming planting season.

THE genus lilium contains so many species, varying to such an extent in their behaviour under cultivation, and so many species about which little or no experience has been gained, that it is impossible to lay down stereotyped rules for the cultivation of the genus, or even to divide it into exact groups. Moreover, lilies often behave quite differently in various parts of the country.

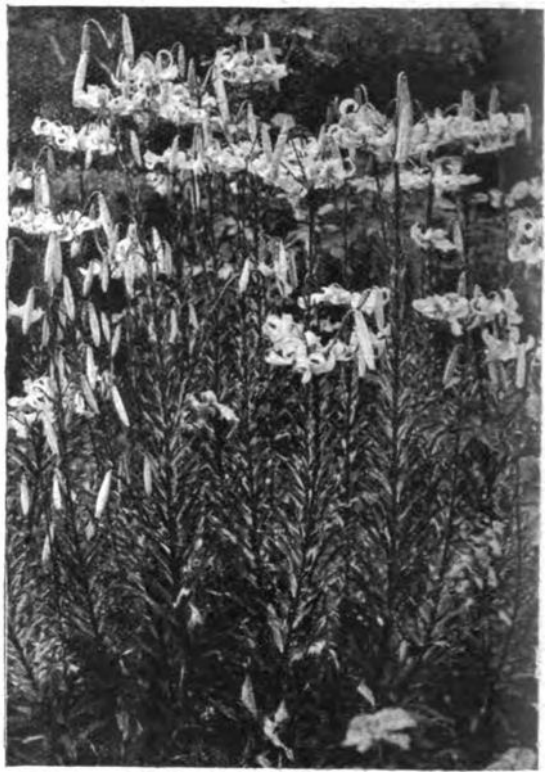
With regard to their cultivation, we may divide the species roughly into three groups, according to the soil and general conditions which seem to suit them best.

SOIL AND SHADE.

Firstly there is the group which will thrive in ordinary soils, providing that they are given plenty of moisture at the roots and full exposure. Many of this group are obviously of value for the herbaceous border, in which it is undesirable to have to introduce special composts where this can be avoided. Moreover, most of these lilies are comparatively easy to grow and also delight in full sun, so that they are undoubtedly well suited to the border. The usual preparation, such as deep digging and moderate manuring, will suffice for this group. Thus, a good stiff loam will suit them excellently; while if the soil is heavy to start with, it should be lightened by the addition of sand and rotted stable manure. If it is very light, cow or pig manure should be added; while peat and leaf-mould help to retain the moisture in the soil, and are always beneficial to lilies.

An important characteristic of practically all the species is that they derive considerable benefit from having their roots thoroughly shaded against hot sun, and it is particularly essential to pay careful attention to this in the case of stem-rooting varieties. Thus, in planting a herbaceous border, the lilies should be set in small groups and in the neighbourhood of plants which produce fairly dense foliage, but which do not grow tall enough to hide the blooms of the lilies. Senecio Clivorum, achilleas and artemisias, for instance, would all be suitable for planting in conjunction with lilies, for they would provide the necessary shade at the roots without interfering with the flowers.

With regard to planting we may consider the details that apply to lilies in general, irrespective of groups. The best time for this is October or early in November, a day being chosen when the soil is in a moist condition, but by no means sodden; moreover, the ground should be free from frost if possible. On a very heavy soil, or in the case of imported bulbs that do not arrive in this country until March, the planting must be deferred until that month. It may be noted here that certain lilies imported annually, notably L. auratum, are often dug prematurely in Japan to arrive in time for autumn planting and these bulbs should always be avoided in favour of a winter consignment, to be planted in March.



A CLUMP OF THE NANKEEN LILY (L. TESTACEUM).

As we shall see later, L. candidum has to be planted at the end of July or early in August.

DEPTH TO PLANT.

The depth of planting bulbs must be regulated by the natural vigour of growth of the different species and must depend upon whether they produce stem roots or not. Thus, the most vigorous stem-rooting kinds, such as L. auratum, may be planted at such a depth that the top of the bulb is from 6ins. to 8ins. below the surface of the soil, so as to allow plenty of soil for the stem roots, while L. croceum, L. longiflorum, L. tigrinum, etc., may be from 5ins. to 6ins. and those with quite small bulbs, like L. concolor and L. rubellum, require only 3ins. or 4ins. Of the kinds that do not develop stem roots, the most vigorous ones like L. candidum and L. Martagon should have about 4ins. of soil over the bulb and the weaker ones an inch or so less. L. giganteum is an exception, as it only requires the top of the bulb 4ins. below the surface of the soil. Finally, the planting must always be rather deeper on a light soil than on a heavy one. It is a good plan to put a little silver sand in the bottom of each hole.

SURFACE MULCHING.

As regards the cultural routine with lilies, there is little to be done except giving the beds an annual top-dressing of decayed manure early in the spring. This operation serves three purposes: it prevents the evaporation of moisture, it provides an invaluable rooting medium for stem-rooting kinds, and, finally, it enriches the soil. Although the top-dressing should be given to all lilies, it is particularly essential to provide it for the species that produce stem roots, for not only do these benefit greatly by the rich food which they are able to extract from it, but they are also protected by it in their young stages, while during the heat of summer the manure keeps much valuable moisture in the soil, which would otherwise be lost through evaporation.

Finally, it is important to leave the bulbs undisturbed, as long as they are doing well, for many species only reach the height of their beauty several years after they have been planted.

The following species may be treated in this way:

L. candidum (the common white or Madonna lily), was the first species to be cultivated in this country and for scent remains unequalled by any more recent introduction. The bulbs should not be interfered with when once established and will often thrive for years when left untouched as they are in cottage gardens. When it is necessary to transplant, this must be done in August, as the bulbs carry foliage almost throughout the year.

L. pyrenaicum, an old species with small yellow reflexed flowers. It is one of the earliest to flower and perhaps the easiest of all to grow.

L. tigrinum, the well known tiger lily, is very hardy and should be represented in every border. In the variety, Fortunei, the stems are covered with a woolly down, the flowers being borne in great quantity, though they are rather paler in colour than those of the type.

A FINE JUNE BORDER LILY, L. DAURICUM.

Digitized by Google

L. croceum, the orange or cottager's lily, is a popular species, with very brilliant orange flowers, spotted with crimson and held nearly erect on stems up to 6ft. high.

L. testaceum (L. excelsum).—The beautiful Nankeen lily, a very distinct species by reason of the clear nankeen tint of its flowers and one of the most valuable garden plants in the genus. The exceptionally graceful flowers, with their petals nearly as much reflexed as those of the Martagon lily, are borne on stems 6ft. or 7ft. high, under favourable conditions, and the plant is quite hardy and as easy to grow as L. candidum.

L. bulbiferum, so called on account of its regular production of bulbils in the axils of its leaves. It is one of the best for an ordinary border, reaching a height of 3ft. or 4ft. and bearing heads of deep orange red flowers early in June.

L. dauricum (umbellatum), and its many varieties are invaluable for the front of a herbaceous border. The large, erect flowers, varying in colour from pale orange to orange red in the different forms, are borne in terminal clusters on stems little more than 2ft. high.

L. elegans (Thunbergianum), a still more dwarf species and remarkably prolific of varieties, which range from lemon yellow through orange red to blackish crimson.

L. Martagon may be treated either with this group or with the next, very slight shade apparently being beneficial to it. It is one of the oldest and when massed with its white variety, one of the best and most graceful species of the genus.

L. monadelphum is another species which it is difficult to assign to either class, as it will often thrive in partial shade and again with full exposure. It well repays trouble in cultivation, however, bearing large drooping wax-like flowers, varying from clear citron to deep yellow and more or less spotted.

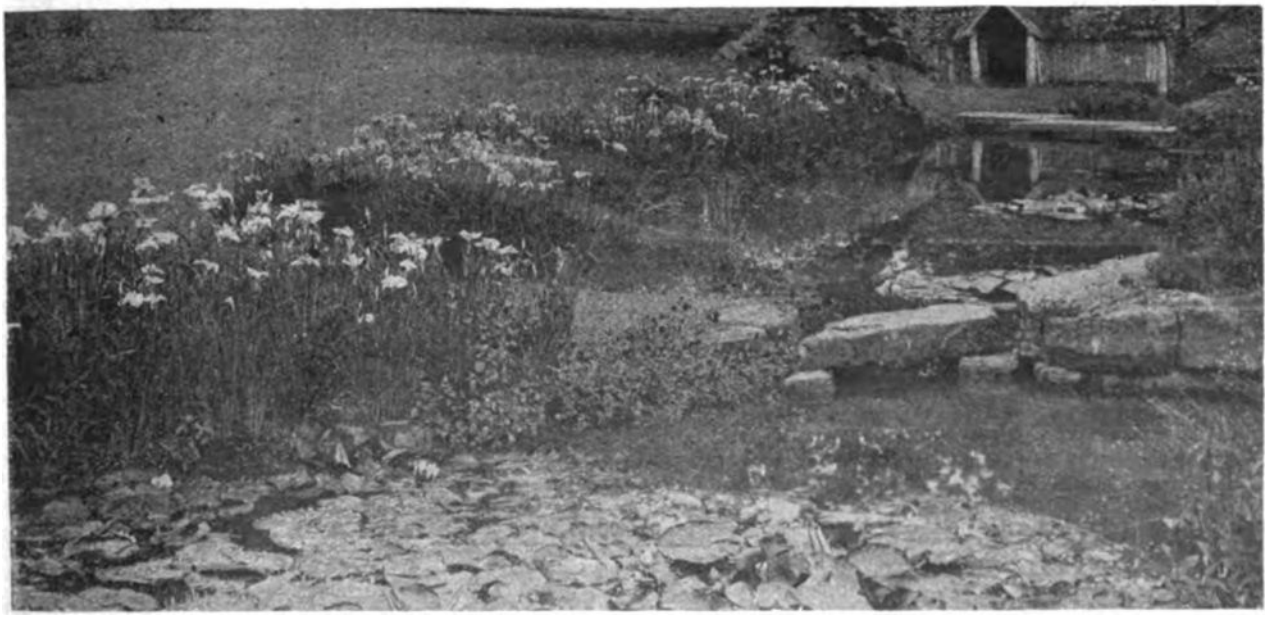
L. regale, is a much newer species than most of those previously mentioned. Nevertheless, it has proved very hardy and being well suited by a good loam and a fully exposed position, is an ideal lily for the herbaceous border. The large white trumpet flowers, suffused with purple outside and pink within, are of great beauty, held in a more or less drooping position on stems up to 3ft. high. F. R.

A FINE GROUP OF LILIUM REGALE IN THE SHRUBBERY BORDER.
Note how the necessary shade is provided over the roots and lower part of the stems by planting the lilies among low-growing rhododendrons.

IRISES FOR MOIST SITUATIONS

Not all irises will grow in moist places in the garden. The following article mentions a few of the best kinds which will succeed round the edges of a small pool. There are few plants which look more attractive in such a position.

SOME of the most effective decorative plants for planting in moist corners of the garden belong to the genus iris. Not all classes of iris enjoy a damp situation and those suitable for this purpose mostly belong to the apogon section of the genus, although a few such as I. xiphioides and its varieties are extremely useful. The apogon section consists of beardless irises, with a creeping rootstock and includes the following species, suitable for waterside planting, *viz.*, I. Kæmpferi (better known as the Japanese iris), I. sibirica, I. pseudacorus, I. versicolor I. Delavayi, etc. All these kinds need an abundance of moisture during their growing



A HAPPY COMBINATION, IRISES AND WATER LILIES WITH OTHER MOISTURE LOVING PLANTS FRINGING THE MARGINS OF A SMALL POOL.

Digitized by Google

season and a rich soil free from lime. Their colour range is from white to purple and blue with I. pseudacorus as yellow. There is an easy method of determining whether an iris needs a moist situation. The method consists in holding a leaf up to the light, the presence of minute black specks dotted all over the tissues is an indication that the species or variety is moisture loving.

Irises should be planted in large clumps for effect, in some cases close to the water's edge, as in the illustration of I. sibirica, in others a little way back from the edge, the edge being planted with other moisture-loving subjects, such as the yellow mimulus, Mimulus luteus or the forget-me-not. A very useful plant for planting with groups of iris is Sparganium ramosum, the bur reed, which has bright green foliage and sets off the waxy bluish green foliage of the iris and the various colours of the flowers very effectively.

On the opposite bank of the pond or at one end, as in the illustration of I. Kæmpferi, a group of those handsome foliage plants, the gunneras, may be planted. Gunnera manicata will be excellent for this purpose.

The irises which are most suitable for this class of work are I. xiphioides, sometimes called the English iris. This is a bulbous iris and is ideally suited for planting at the waterside. The leaves are tapering and 12ins. to 18ins. in length, while the stem is somewhat shorter. It is very hardy in this country. Flowers are borne in terminal heads, two or three to a head. In nature the colour is deep blue, but an occasional white is found, but garden forms have been produced whose colour ranges from white, light blue, purple to deep blue. The best time of planting is September to October and the season of flowering is June and July Good garden varieties are Mont Blanc, white; King of Blues and Othello, blue; P. C. Hooft, purple; and Bleu Celeste and Tantalus, light blue.

IRIS KÆMPFERI MAKES A MOST EFFECTIVE SHOW AT AT THE EDGE OF A SMALL POOL

I. Kæmpferi and its varieties, the Japanese water iris, is best grown in raised beds, intersected by channels through which the water can be led during the growing season and which can be kept dry by blocking the ends of the channels in winter. During the winter resting period an application of farmyard manure or liquid manure applied to the crowns will be of great benefit. There must be no lime in the soil where I. Kæmpferi is to be grown. Plant immediately the flowers are over or in the early spring. They flower in June. There are many varieties.

I. sibirica and its varieties, orientalis, flexuosa, etc., require a cool, moist soil, rich in humus, without any lime. They have tall, hollow stems which are well above the foliage and the flowers are borne on long pedicels. The flowers are typically blue with a network of veins on a white background near the centre of the falls. The best time to plant is in September or in April. The plants may be increased by division and plants may be produced from seed, which should flower in the third year.

Iris pseudacorus is about 3ft. in height, has large yellow flowers and is specially suited for marshy ground. I. versicolor is similar, but of a purple colour. Plant in September or October.

I. Delavayi is very desirable for the waterside, as it flowers in June and July, when the I. sibirica is over. The flowers are larger than I. sibirica and of a rich red violet colour.

Other species and their varieties which are suitable for planting by the waterside are: I. fulva, I. albopurpureus, I. ochroleuca, I. Monspur, I. chrysographes, which should be planted in early autumn, when division can be done, I. Wilsoni, etc. [H. B.

PROPAGATING ROCK PLANTS

A large number of rock plants can be propagated from cuttings in the summer, and the stock raised in this way is far superior to chance divisions, often very imperfectly rooted, made in the autumn.

IT is absolutely necessary to devote a cold frame to the work, for if put in the open ground most of the cuttings would shrivel up before they became rooted. The frame should be stood in full light, but to save the cuttings from excessive heat it is best to place it so that it faces the north. A good layer of ashes should be put in the frame to serve a double purpose, providing the cuttings with a moist cool bottom, and ensuring their not being too far away from the glass. If the ashes come to within 6ins. or 8ins. of the glass, so much the better for the cuttings.

After trying various methods I have found that the best plan is to put the cuttings in small pots, 3ins. or 3½ins. in diameter, rooting from four to eight cuttings in each. In some cases it is best to put the lesser number in a pot, and then plant them out in the autumn without separating them; but things that take up a fair amount of space can be rooted close together, and potted off into small pots when they start growing.

The little pots should be well drained, and the best soil for general use is a mixture of 4 parts light loam, 1 of leaf-mould, and 1 of silver sand. Some plants that are peat lovers root better in peat and sand, and more coarse sand or rock chippings can be added for moraine subjects that do not care to have much soil around them. Adding a top layer of dry sand just before putting in the cuttings greatly facilitates the rooting process.

A cheerful optimist might advise keeping the frame moist and absolutely closed until the cuttings rooted, but experience teaches that it is better to give a little air night and day, and it will be enough to push the light down 2ins.

The cuttings should be watered as often as they need it, giving attention to each individual pot, missing those that are already moist enough. One great point is to keep the cuttings from flagging, and in hot dry weather it is advisable to spray them with soft water during the early morning and late afternoon.

Even with a frame facing the north there is a fear of getting too much sunshine, and a thin screen, such as a piece of tiffany or a mat, should be put over the glass during the brightest hours of a sunny day. A thin coat of whitewash can be used, but these little mountain plants are lovers of light and need all they can get on our cloudy days.

The majority of things will root in three weeks, though others may take much longer, and when rooted they should gradually be given more air, but not fully exposed until they have been potted off and are well rooted in the new soil.

Some subjects that root freely from summer cuttings are achillea, æthionema, alyssum, aubrietia, cistus, erysimum, dianthus, dryas, erodium, geranium, helianthemum, iberis, linum, lithospermum, origanum, phlox, thymus, viola, veronica and zauschneria. Fresh young growths of these from 2ins. to 3ins. long make excellent cuttings. It may be well to mention that Lithospermum prostratum and its variety Heavenly Blue are lime haters, and they only root freely in a soil devoid of lime, so it is best to treat them to a mixture of peat and sand.

When dealing with saxifrages of the mossy kind it is best to dibble three or four rosettes in one pot for planting out in the autumn without disturbance. A pocket filled in this way will be one mass of bloom the next season. New rosettes can be taken off the encrusted saxifrages, the larger ones being given single pots and the smaller ones put in three or four together. The precious kabschia or cushion saxifrages should not be interfered with during summer, for it is best to divide them just after they have flowered in spring or during the early autumn. Pieces can usually be got from them with roots already formed, and they can go back in the moraine or a pocket.

The smaller tufted androsaces are too tiny to be turned into cuttings and can be divided in autumn, though it is sometimes possible with large plants on hand to pull off sprays and root them in the cold frame. Larger varieties making runners, after the manner of A. sarmentosa, can have the runners taken off and inserted as cuttings, getting the soil right up to the lower leaves.

That gem of summer flowers, A. lanuginosa, will root freely if the young growths are put in as recommended for ordinary things. It is the safest plan to keep the young plants in the frame during the winter, for, though they are cold proof, they do not like the damp of our winters.

Things that increase with great rapidity, such as the ledums and sempervivums, usually give a sufficient stock by division in the autumn; but choice or rare varieties can have little pieces taken from them, to be pricked off in pots like cuttings. T. H. WORLD.

SAVE YOUR OWN SEEDS

Now is the time to go round plants that have finished flowering and collect the seeds when they are ripe. These can be sown immediately after gathering. All extra fine specimen plants should be noted and seed collected from them. There may be a striking break among the seedlings next year which is an improvement on the parent plant.

IT is most fascinating work to collect and sow your own home-grown seeds, and by careful selection of the parent plants a good strain may be worked up. Extra fine specimens should be noted when they are in flower and marked with a piece of coloured wool tied round the stem; or, better still, with a numbered wooden label, particulars as to variety, colour, height, etc., being entered in a notebook under the number of the label.

Of course, seed will not always give seedlings of the same type as the parent plant, and this is particularly noticeable in varieties of lupins, delphiniums and pyrethrums, which are the result of highly specialised hybridisation and selection. Still, there is always the hope of getting some at least true to colour, and a few may even be improvements on the parent plant.

Generally speaking, it pays to save seed from selected plants of the following, though this is to be taken as by no means an exhaustive list: Geum, anchusa, aquilegia, delphinium, sweet william, Canterbury bell, foxglove, lupin, gaillardia, campanula, single pink, hollyhock (take care that the parents are not infected with the rust disease), scabiosa, coreopsis and antirrhinum.

Extra fine alpine plants may also be treated in the same way, but the majority of them can also be propagated from cuttings, which provides a surer method of getting plants true to colour. Rock and bog primulas, however, are preferably raised from seed, and fresh seed will always germinate quickly and easily. It may take anything from six weeks to six months, however, if sowing is put off until the following spring.

A good strain of such annuals as candytuft, pot marigold, nigella, eschscholtzia, etc., may soon be worked up if a few extra good plants are allowed to seed, all the poorer forms being pulled up and burnt as soon as they have finished flowering. These annuals may be allowed to scatter seed where they stand, or, if preferred, the pods can be gathered and sown in the desired positions either in autumn or early spring.

In all cases where the seeds are to be gathered the pods should be plucked before they are fully ripe, or they may split open and scatter their precious contents over the garden. The pods should be hung head downwards over an open sheet of paper and left thus until they have shed their seeds.

Many people prefer to leave the pods unopened until the spring sowings, but I find it better to extract the seeds and keep them in separate *glazed* paper envelopes, with particulars of the variety, when gathered, and any other notes desirable written on the outside.

The following instances, taken from my 1926 records, will illustrate how quickly fresh seed will germinate:

Single Pink.—Collected July 29th; sown July 31st; above ground August 6th. Most of these have flowered well this year, and all will make fine plants for next year's display.

Tree Lupin.—Collected July 29th; sown August 4th; above ground August 9th. Many have flowered this year, some being fine bushes about 4ft. in height already.

Musk Mallow.—Collected August 5th; sown August 5th; above ground August 12th. All have flowered exceptionally well this year, and have been of the utmost value for cutting.

One last word. Seeds of perennials collected before the end of August may be sown straight away, but after August it is better to keep them until spring. Annuals may be sown up to the middle or even end of September, but later sowings than this are not advisable, though sometimes they succeed on very light soils. W. H.

LONG LIFE FOR CUT FLOWERS

A few hints on the treatment of flowers used for house decoration.

TO make flowers last for any length of time in water is merely a matter of following a few common-sense rules, though, of course, there are certain blossoms that, even growing on the plant, have at the most but a very short span of life. The blue flax is one of these, for by mid-day most of the newly opened blossoms will have fallen, though a few may persist the whole day through. The lovely blue alkanet is another flower that does not stand picking, and border lupins, handsome though they be, seem to drop after the first two or three days in water.

Messrs. Sutton and Sons

AN ATTRACTIVE BOWL OF PINK CLARKIAS.

In gathering flowers, the first important point is to pluck the blossoms in the early morning, before the sun has dried the natural juices in their delicate petals. Where the flowers cannot immediately be placed in their vases, it is necessary that they should be stood up to their "necks" in a pail or wide jar of water, the pail being placed in a cool part of the house. It is almost needless to say that newly opened buds will last longer than full blown flowers, and such kinds as Shirley poppies and eschscholtzias may be picked even before they have burst the bud. With poppies and chrysanthemums, it will also pay lightly to char the ends of the stalks in a candle flame, for in this way their life may be much prolonged. Dwarf annuals grown for cutting should be pulled up by the root and, when the soil has been washed away, put straight in their vases without further preparation. It is surprising how long a clarkia or godetia will last treated in this fashion, and furthermore, even the immature buds will go on developing and opening for some time after the plant has been uprooted. Branches cut from flowering shrubs will last much longer if the ends of the stems are split with a sharp knife, the reason for this being that they thus present a much greater area for absorption of water.

One often sees different substances recommended for dissolving in the water with cut flowers, including such widely differing stimulants as salt, sugar, aspirin and camphor. There is no doubt that a tablet of aspirin dissolved in tepid water will do wonders towards reviving faded flowers, but the writer has never experimented with the other substances mentioned, and so is in no position to make comments on their respective merits. Charcoal, however, should always be used in vases, for it keeps the water clean and sweet, and obviates the necessity for changing water every day, a great consideration where there are large numbers of vases to be dealt with every morning. Vases containing foxgloves delphiniums and other soft and leafy stemmed flowers, should have the water changed daily, however, for these sappy growths soon decay under water. For this reason I prefer such flowers as poppies, scabious, coreopsis, etc., these having hard, wiry stems which may be left in the same water for a week or more without sign of deterioration.

One fertile cause for the early fading of cut flowers is that they are crowded too tightly in the vase. Not only do they look clumsy arranged thus, but also they are more or less strangled when crowded together, and soon fade for lack of air and water. Another fault is to allow the ends of the stems to rest upon the bottom of the vase. The result of this is obvious; water has no free access to the cut part of the stem, and, consequently, even though the vase be full of water, the flowers die of thirst, as they only absorb water in any quantity through the end of the stem. A third mistake is to leave flowers in a room where gas is burning. This is fatal to both pot plants and to cut flowers; the fumes given off by the gas are probably partly responsible, but besides this the atmosphere is dried and heated so that flowers and plants quickly dry and wither. Finally, let it be urged that all vases be filled with water before the flowers are arranged. B. D. S.

THE BUSY MAN'S PAGE

Taking Cuttings of Pinks.

PINKS are old-world border flowers, appreciated wherever the plants are grown. The plants flower during warm weather, but the young plants, cuttings or pipings must not be exposed to drying winds or hot sunshine, else they will shrivel and soon become useless. The present is a very suitable time for inserting cuttings or pipings. Before any are severed from the parent plants, the boxes, pots or beds in frames or cool borders outside should be duly prepared. A light compost must be provided for the cuttings to root into, but a thin layer of heavier soil just below the light compost will be an advantage. The top layer is made light by adding coarse sand to it, and the surface itself should be covered with sand about half an inch deep. Make the bed of soil very firm, then take a bucketful of water to the pink bed and, as the cuttings are detached from the parent plants, place them in the water; prepare them from the water and insert at once. In preparing the cuttings, simply remove a few of the basal leaves to have a clear stem for inserting in the soil. Water at once through a fine rosed watering can and shade from bright sunshine. Occasional waterings will be necessary, but not any further attention until the cuttings are well rooted, beyond seeing to it that if they are in the open they are made firm again in the soil, when it is observed that earthworms have loosened them. If not immediately attended to in such cases the cuttings will fail to emit roots.

Summer Treatment of Chrysanthemums.

IT is very important that the pots containing chrysanthemums should not be crowded, as the lower leaves are sure to suffer if the specimens are too close together. It is best to place the plants quite a foot apart on a firm bed of ashes. An open position should be chosen where the plants can enjoy a good many hours of sunshine each day. By this time the plants will have been placed in their flowering pots. Provide stakes for the plants, or support them by placing between wires which are carried from strong stakes driven into the ground. As fast as side shoots grow pinch them out, retaining only main stems and main leaves. At the end of July, or early in August, buds are again formed, the first, known as the "break-buds," having been rubbed away in April or May. The first crown buds, as those produced in July are called, may be taken to form the flower, and in such a case shoots round the bud are removed. By pinching out the first crown bud and retaining several of the surrounding shoots, other buds, known as "second crowns," will be formed in a few weeks. In the case of most varieties these second crowns are the ones taken. Water carefully with clear water until the end of July, when the roots will be growing round the ball of soil in the pot; then feeding may commence. Clear soot water, given every third day, will suffice for ten days; then give manure water diluted to the colour of pale brandy. Both soot and manure should be tied up in bags of coarse material and immersed in vessels of water for several days prior to use. All artificial manures should be given strictly according to instructions.

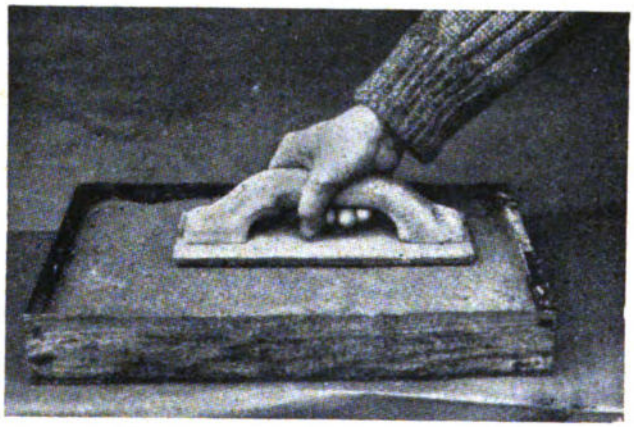
The Month for Cuttings.

OF all times in the year July is the best, so far as the majority of plants are concerned, for the taking of cuttings. With the exercise of a little care it is possible to increase one's stock of plants to an almost indefinite extent. Slips from privet, euonymus, laurel, shrubby veronicas and many other kinds taken now with a heel of matured wood will root in sandy soil if the position is well shaded. In most cases the cuttings will have taken root by the autumn, when they can be transplanted. Rose cuttings taken now are almost sure to give good results. Each cutting should be 6ins. to a foot in length, and if there is a heel so much the better. Rub away buds and leaves from the lower one-third of the slip and bury this in the ground. Choose a shaded spot where the soil is well broken, but not too sandy, and a big percentage of the cuttings will soon be rooted.

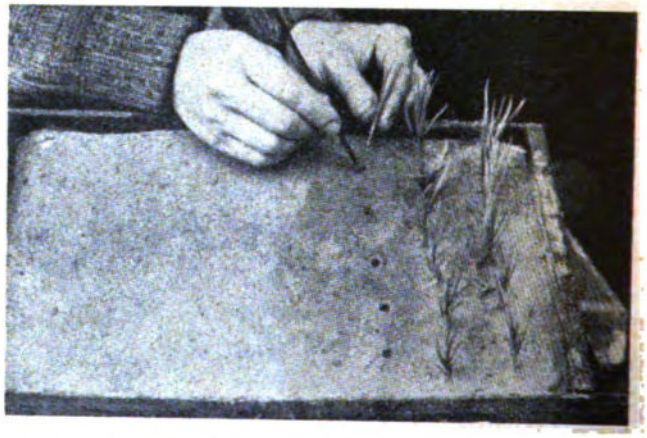
The zonal pelargoniums (geraniums) can also be propagated by means of cuttings at this time. Always make the cut below a joint and allow the slips to remain exposed to the air for a few hours before setting them in sandy soil. Watch the cuttings closely and remove any fading leaves or mildew may appear. Fuchsias, marguerites and calceolarias are also easily propagated by means of slips in July. Cuttings removed from bedding begonias root freely in very sandy soil which is kept moist and before the end of the season will have developed quite nice corms. These plants will provide a late display of bloom in a greenhouse before they pass into their winter rest. Propagation by means of leaf cuttings is an interesting form of culture which may be carried out in the case of gloxinias, streptocarpi and the Rex begonias. One may just press the stalk of a well developed leaf into light soil and, in this way, a fresh plant is secured. A number of plants may be obtained from one leaf by cutting through the main ribs in several places and then pegging the leaf down on to moist soil. At each cut part a fresh plant arises, and, when rooting has taken place, these may be divided and potted up separately.

Tying-in the Best Shoots of Roses and Climbers.

WHEN roses and climbing plants have made satisfactory progress, it means that the plants, having grown well, have in some cases become a thicket of growths. It is when the plants are in this state that the inexperienced cultivator is at a loss as to how they should be treated. But the wise cultivator will, every year, treat the plants judiciously in this respect right on from the first year of planting and then there never will be any serious difficulty to be faced. Climbing roses will bloom year after year on the old branches, but the sprays and flowers are small and become smaller each year. By making a judicious selection of the best of the current year's shoots and training them in so that light and air will reach them freely, they will mature. Sometimes it is advisable to cut out entirely a few very strong young shoots, because they will not mature during the year and, being immature, they will not survive a severe frost; even if they did they would not bear flowers the next year. So some judgment should be exercised when engaged in cutting-out some and tying-in others. As a rule it is advisable to retain the selected shoots of all climbers their entire length at this season. If the tips are cut off, more side shoots will grow, forming a tuft near the end—a most undesirable condition. The best time for the removal of any unripe ends of long shoots is during October or early in November, then there will not be any more young growth this year. Where roses and other climbing plants are grown to cover pillars, trellis or wall space, the aim of the cultivator should be to get the basal or lower parts well furnished with healthy young wood as well as the upper parts.



WHEN PROPAGATING PINKS THE SAND IN THE SURFACE OF THE COMPOST SHOULD BE MADE FIRM.



THEN THE CUTTINGS MAY BE INSERTED WITH OR WITHOUT A DIBBER, TWO INCHES APART.

Digging Early Potatoes.

WHEN digging potatoes it is always best to insert the fork in a perfectly upright position and to make sure of getting it well down under the root before raising the soil. Dig over the ground a second time to see that no potatoes have been left in the rows. With the early potatoes dig only from day to day just as the supplies are needed. To dig a week's supply at once will mean that the tubers, which are held over for some days, will lose a good deal of their flavour.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Decorative Room Plants.

ROOM plants if kept on tables away from the light soon turn sickly. They should, therefore, be placed occasionally in the window, or else in a greenhouse or cold frame. Never put the plants out in the rain except in the very warm weather. Sponge the leaves occasionally, or take them out of doors and syringe them. Water only when the soil is dry, but when you do water give the plants a thorough soaking. Plants need air so keep the windows open. Remove dead flowers and leaves. Turn the plants round once a week to keep them upright. It is a mistake to allow water to stand in the saucer beneath the pot.

A SELECTION OF PLANTS.

For Hanging Baskets.—Ivy-leaved geraniums, Campanula isophylla, rat's tail cactus and pedlar's basket.

For Deep Shade.—Ferns, such as Asplenium bulbiferum, Pteris cretica and elk's-horn; aspidistras, preferably the coloured-leaved kind; aralia, india-rubber plant and palms.

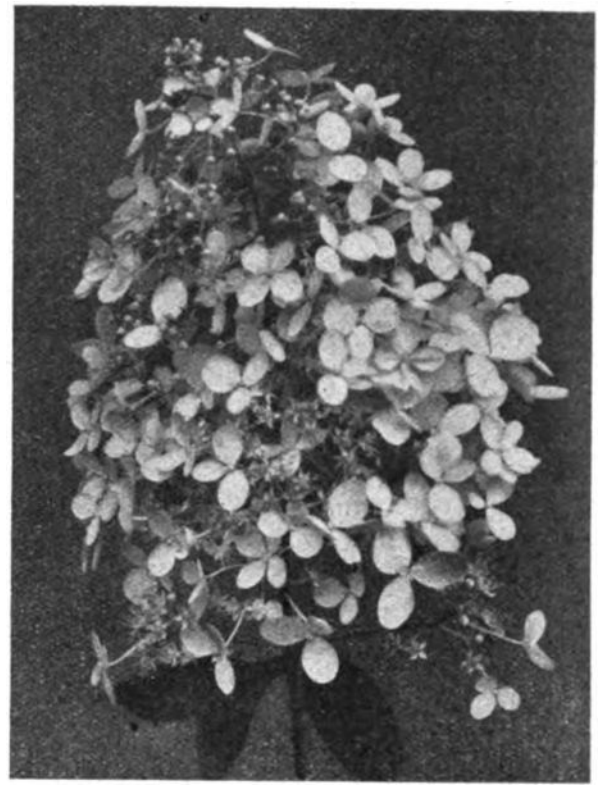
For the Window. — Cacti, geraniums, pelargoniums, Scarborough lily, fuchsias and hydrangeas. If a greenhouse is available, the sun-loving plants are best grown there and brought indoors for decorative purposes when required.

Sow Virginia Stock.

GARDENERS are always looking ahead to what their borders will be like next year. To those who are impatient by nature, this looking ahead is very trying. They ask for some magic flower which can be sown to-day and in bloom in a few weeks. Of all the flowers which mature rapidly I imagine none can produce such a "lightning garden" as Virginia stock. A judge who was visiting gardens in one of the most congested districts last week remarked to me "Isn't it wonderful what Virginia stock can do? You find a grimy street, with a tiny back garden in it, almost neglected. But at the last minute someone has thought to sow all the path edges with Virginia stock, and now the effect is charming." So, if you have just become possessed of a garden which has hitherto grown tom cats and brickbats, surprise your friends by filling it with bloom before the season closes. Virginia stock, mignonette and candytuft would all flower before the end of the season if sown now.

Exhibition Marrows.

THE season for flower and vegetable shows has already commenced, and already I have heard laments that the dry weather of early June made the vegetables late and, in consequence, of *small size*. It reminded me that one of the most common of errors among amateur exhibitors is the cutting and staging of overgrown marrows. Size is not important, except in the case of marrows intended for jam. Tenderness comes first, and the second consideration is suitability for the average table. A couple of small marrows, young and tender, and only large enough to fill your two hands are more likely to win the judge's favour than large coarse fruits. Also, if a couple of marrows are demanded in the schedule, choose a couple that makes a pair. They will look far better than one large one and one small one placed together.



HYDRANGEA PANICULATA IS A FINE HARDY SHRUB FOR THE SMALL GARDEN.

Its flower heads are most decorative.

A Remedy for Potato Blight.

WE can, if we will, purchase "immune" potatoes, that is, potatoes that are immune to the dreaded wart disease. But we do not find in our catalogues any offers of seed potatoes of varieties immune to the potato disease, which is the most widespread of all diseases that attack this crop. Our only remedy, therefore, is to spray—not only when we notice signs of the disease, but before the disease has been able to put in an appearance in our plots. The first sign of the disease is the appearance of brown patches on the leaves. If the weather is favourable to the development of the disease, the whole stems and leaves may become black and rotten in a few days, and may develop a very unpleasant smell.

The best spray to use is Bordeaux mixture, and this should be used in the middle of July and again after an interval of three weeks. Where only small quantities of the spray are needed it is advisable to purchase the compound ready made.

Brompton Stocks.

IN the early days of summer, when our gardens are full of promise, but, alas! not always in bloom, the Brompton stocks will bring a foretaste of summer joys into the mixed border. These plants are extremely easy to raise, and although they are comparatively short-lived among the perennials they often last for several years in a fairly sheltered situation. Now is the time to sow seeds, which should be allowed plenty of room to develop. Transplant the seedlings as soon as they are large enough to handle, and do not despise even the weakly-looking ones, for they may prove to be the best colours. From 8ins. to 12ins. should be allowed between the plants when they are put out in the nursery bed.

In cultivating good plants of these stocks, the aim is to obtain woody growth before the very cold weather sets in. Should the plants make rapid growth during September, it is a good plan to lift them and replant elsewhere, for this treatment will induce the new sappy growth to harden and the plants will be less susceptible to frosts. If the garden is very exposed, it may be necessary to provide protection during the coldest months.

A good place to choose for the Brompton stocks is under the shelter of trees and shrubs, where they will succeed and yield an abundance of colour to fill the gap between the spring bulbs and the summer flowers.

SINGLE DAHLIAS MAKE EXCELLENT CUT FLOWERS.

Just now a sharp watch should be kept for earwigs. Thin the shoots, cut off dead flowers and keep the centre stems securely tied to a stake. A surface mulch of littery manure is beneficial.

WORK IN THE FLOWER GARDEN

How to Succeed with Lachenalias.

THE first of these beautiful flowers was introduced into this country about the year 1774. Since that time the lachenalia has been more or less popular with professional gardeners, but now that the hybridist is busy, its future popularity among amateurs, as well as professionals, is assured.

A bulbous plant, it throws out large, thick, fleshy leaves, which are mostly handsomely mottled with dark ruddy spots. The flowers are pendulously borne on spikes and are tubular in shape, somewhat like a foxglove in miniature. The blooming period is early spring and the blooms themselves last well over a month.

The culture is simple, the only necessity being a cool or cold greenhouse, the latter being preferable from my point of view. The best time of the year to commence growing lachenalias is the end of July. The bulbs can be planted later, but the results will not be so good, and the effort to get them in at this time will be well worth the trouble involved. The best pots to use are those 5ins. in diameter, each pot being sufficient to hold six bulbs. Put one crock in the bottom of each pot and then fill with a compost consisting of two parts sandy loam and one of leaf mould. The bulbs should not be planted too deeply, in fact, if they are only just covered with soil, it will be sufficient. The best position for the first few weeks is in a cold frame, but underneath an airy staging in the greenhouse will do, if no other place is available. One good watering should be given directly the bulbs are planted, and this should be sufficient till definite signs of growth are forthcoming. Water must then be given regularly, but sparingly, till the young leaves are about an inch long. When the plants have reached this stage of growth, water must be used freely and frequently till the bloom appears during March and April. Directly the blooming period is over, water is gradually withheld and the foliage allowed to die off naturally. From this stage to repotting the following July, it is important to place the bulbs in a position where they will be baked by the sun. They should be left in the pots in which they were grown and no water given during this period. The ideal place is on a shelf close to the roof of the greenhouse.

A SEEDLING LACHENALIA OF GOOD HABIT BEARING A PROFUSION OF ORANGE COLOURED BELLS.

These are first-rate plants for the cool greenhouse and seed should be sown at the end of this month for a flowering display at Christmas.

The following varieties are well known :

L. Nelsoni.—A handsome hybrid with large golden bells and reddish stems. Height 1ft.

L. pendula.—Scarlet bells tipped with green. Height 8ins.

L. luteola.—Light yellow bells, shaded green and orange. Height 9ins.

L. tricolor.—A lovely blending of fiery red, orange and green. Height 9ins.

L. Monte Carlo.—A large flowered improvement of tricolor. Height 1ft.

L. Siam. — Canary yellow bells, self-coloured. Height 1ft.

Whitewell Seedlings.—A glorious mixture. Heights various.—G. E. W.

Roman Hyacinths for Christmas.

THE best blooms are obtained from Roman hyacinths when they are bought as early as possible and potted up at once, for no amount of forcing can atone for lateness in both these respects. Procure them now. Properly planted and treated, they will be in flower early in December, and can be made to supply a succession over a long period. Fill boxes, some 4ins. deep, with any good compost, not too fine, and place the bulbs in the compost so that they practically touch one another. If pots are preferred, select medium sizes, 6in. or 7in., and place as many bulbs in each as it can conveniently hold. Thoroughly water the boxes or pots, place on the path outside and cover up with a depth of 6ins. of fine sifted ashes ; water the ashes if they are dry, and never let them become really dry again. A month later examine the bulbs ; when the growth is some 2ins. long, remove the pots and place in a frame ; cover partly from sunshine for two days. Introduce a few at a time into the greenhouse, beginning with the first boxes or pots about the third week in October or a little later. In a temperature round about 60° to 65° Fahr., growth will be rapid and bloom will appear in December. Successive batches keep up the bloom and ensure plenty round about the festive season. Feed plants with liquid manure when buds appear.—LANARKSHIRE.

Dwarf Irises to Grow.

ALTHOUGH the iris has become a favourite everywhere of late, there are many dwarf species almost entirely overlooked by the ordinary gardener and, after having my annual overhaul of "what has done well," I feel constrained to name a few ; a comprehensive review is impossible in a brief space. Iris pumila seldom tops 8ins. in height and contains the fine varieties gracilis (purple yellow), azureus, atroviolacea, aurea and alba, the name being fairly descriptive in each case. Reticulata, early-flowering like the former, is a delightful species ; the type itself is purple golden orange (I doubt if irises can be described in a few words), and its varieties, histrioides, major and Krelagei, are all distinct and almost as good. Unguicularis is among the earliest to flower ; it and the varieties Elizabeth, speciosa, alba (a delight in winter), Heavenly Blue and angustifolia, need protection when in flower. Less common than any of the above are the species Histrio, orchioides and its blue variety alata and Heldreichii, the "dwarfest" of all ; I am doubtful if some of these are on the market to-day. Among the other irises, Canary Bird, a dwarf bearded variety, is very fine for summer bloom. Chamæiris, a rare purplish white species ; cristata, a veined blue ; ixoides, white blotched with blue ; and gracilipes, a new and very pretty dwarf Japanese variety, are all fine, but difficult to get.—H. A.

Hybridising Plants.

An Interesting Job for Amateurs to Try.

BEFORE we can have seeds, plants must be fertilised or, in plain words, pollen from the stamens must be introduced to the stigma ; this process can, as everyone knows, be carried out by means of a fine brush, and is, of course, frequently done by scientists. When pollen from one plant is carried to another plant of a similar kind we have cross-fertilisation, which generally improves the quality of the progeny of that union ; when we carry pollen from a plant of one species to that of a different species we attempt to hybridise or to produce a new plant. Many of our garden plants are hybrids, artificially produced. Readers who wish to attempt hybridisation must remember that Nature limits the process very considerably ; there must be a certain affinity or similarity between the plants, this similarity being mainly in the flower. We can hope, for example, to get seed by uniting the sweet pea with, say, the garden pea, but it is impossible, as far as we know at present, to obtain a hybrid between a sweet pea and a rose. As there always is a "future" before any new hybrid of merit, the process has many devotees, the results of their efforts appearing sooner or later as "new varieties." When about to attempt the work, take care to cover the stigma-bearing parent (which will eventually carry the seed), from the time when it begins to open out ; remove its stamens, if it has any, as soon as these can be reached and when the flower is "full out," introduce pollen from the selected second parent. The cover must not exclude sun and air ; a piece of gauze or muslin is best, sufficient to keep away insects, until the seed pod begins to ripen.

When the pod is ripe, harvest it, lay it on a sheet of paper in a sunny window and store the seed in an envelope until next season.—A. H.

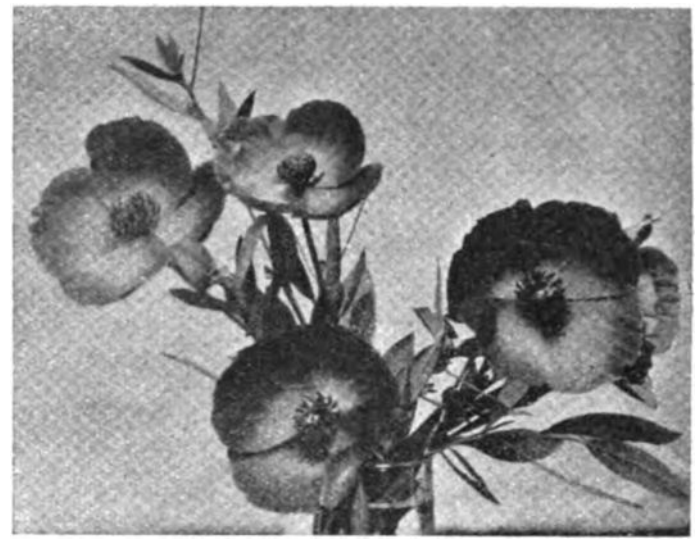
Stimulating Chrysanthemums.

CHRYSANTHEMUMS are frequently overfed, and experience soon proves that exuberant foliage with soft fleshy stems seldom yield the fine result which one might expect from them. Solid stems and healthy but firm leaves are more acceptable to the expert, and feeding should be given with that end in view. One thing to avoid is an excess of stimulating nitrogenous manurial matter of any kind. For this reason sulphate of ammonia and nitrates are probably best avoided and rich manure wash from natural manure ought to be well diluted before it is applied. Again, too early application of stimulants may defeat its own end. As the plants extend upwards the root system fills the pot and, when flowering time approaches, stimulants become necessary. The best manure is a balanced one. Let it be made from natural manure in the dry weeks and from more speedy stimulants in dull, slow-growth weather, the variety proving beneficial in more ways than one. Apply it weak, always erring on that side rather than otherwise, and give it fairly often as the season advances.—CLYDESDALE.

A Charming Sun Rose.

HELIANTHEMUM UMBELLATUM (often erroneously labelled H. rosmarinifolium) is one of the best of the sun roses and one that would be justified in claiming a prominent place even in a short list of the most attractive species. This not only because it is so distinctive in foliage and flower, but because it is such a persistent bloomer. I have grown sun roses of various kinds for many years and not failed to note that H. umbellatum is always the first to come into flower and the last to go off. Even in midwinter here in the west this cheerful little shrub will often give a few blossoms during mild weather. H. umbellatum grows to about 18ins., making an openhabited, slender, upright bush with a tendency to trail. The narrow, leathery leaves, which have white under sides, are a dark lustrous green which makes so telling a background for the milk-white flowers. The latter, borne in long terminal racemes, are about ½in. across, prettily cupped in shape, and they have a faint yellow stain at their base. As with other sun roses, this species may be increased very easily by cuttings. Any short, half-ripened shoots taken in the later summer will strike if potted firmly in sandy soil and placed in a closed frame for two or three weeks. Though so different in appearance from the general run of sun roses, H. umbellatum needs the same conditions. That is to say it will thrive in any well drained soil (if gritty or stony, so much the better) with full sun.—A. T. J.



THE RICH BUTTERCUP YELLOW BLOSSOMS OF THE GOLDEN TREE POPPY,
A fine shrubby plant for a hot and sunny position.

The Golden Tree Poppy.

FEW Californian shrubs excite so much admiration as Dendromecon rigidum, which differs from its ally romneya not only in its entire leaves and the colour of its flowers, but in its more woody nature. This is, in fact, the true tree poppy of California, and I shall not readily forget the first time I saw it on its native Sierra Nevada, its brilliant gold in a setting of blue ceanothus. If undoubtedly rather tender for some places, D. rigidum is hardier than is generally supposed. I have grown it for nearly a score of years, during which it has been subjected to as much as 20° of frost without any serious injury, and this with no more shelter than a low wall, above which its 8ft. branches are fully exposed.

D. rigidum is a vigorous shrub, making long and slender whippy growths. The leaves are narrow and pointed, like those of a willow, and of a soft glaucous tint. The flowers, which are borne at the tips of the branches and side shoots in great profusion, are about 3ins. across. The four broad petals are an extraordinarily rich and lustrous buttercup yellow, and they are centred by a bold cluster of orange anthers. Unlike most of the poppy race, these blossoms are deliciously fragrant and the individual flowers last an unusually long time, The blooming season extends practically all summer. Indeed, the tree poppy is rarely altogether out of bloom, for even in midwinter it will occasionally give a flower or two during a mild spell. This very choice shrub should be given all possible sun and a stony, rather poor root-run. It will stand any amount of drought when established. I have raised it fairly successfully from short cuttings of fresh growths with a "heel," these being potted firmly in very sandy soil and struck in a closed frame. Where one has to depend on the sun for heat the cuttings must be taken fairly early in summer, and when they are rooted they should be potted singly and again placed in the frame until root action is re-established. I suggest this because it helps to avoid root disturbance when plantin out—a frequent cause of loss.—A. T. JOHNSON.

ONE OF THE BEST OF THE SUN ROSES, HELIANTHEMUM UMBELLATUM.
It will thrive in a sunny spot on the rockery, and can be increased by taking and inserting cuttings next month.

A Good Rock Rose.

Cistus purpureus.

THE rock roses constitute a beautiful group of flowering plants, suitable for the rock garden and shrub border, while for dry banks and similar positions they will be quite at home. The plant under notice is said to be a hybrid between Cistus villosus and C. ladaniferus, and it will form a bush or shrub 3ft. to 4ft. high and much more in circumference. The showy flowers are about 3ins. in diameter, the colour being a rich crimson red with a conspicuous dark red blotch at the base of each petal. It is very free flowering, and plants a few inches high will produce blooms of good quality: in fact, cuttings rooted last July were blooming freel in the following May and June. This delightful plant is not quite so hardy as a few other members of the genus, but in many parts of the country it will pass through the winter safely without any protection. It is advisable to take a few cuttings annually and winter them in a cold frame; then, if the old plants are destroyed by frosts, it is an easy matter to replace them in the spring. It should be remembered that they will only transplant when small unless they are grown in pots.—B.

Prepared Hyacinths for Early Flowering.

Flowers by Christmas.

HYACINTHS are not suitable for early forcing in the ordinary sense, but growers who desire to have early flowers can procure specially prepared bulbs for the purpose. The flowers, owing to the process through which the bulbs pass, are not equal to the massive spikes we look for later on; but under fair conditions they produce very good flowers. Crimson, pink, blue, yellow and white varieties are to be had. Order these prepared bulbs at once; pot up three to five in a pot, plunge for a short time, as is done with the Roman hyacinths, then force in a moist heat, in the neighbourhood of 60° to 65° Fahr. With success, spikes 6ins. to 8ins. in length are secured. Prepared bulbs of the miniature or Cynthella hyacinths are also to be had, which, if planted as soon after this as they can be obtained, will blossom in good time for the festive season. Variety is to be had in these also.

TREES AND SHRUBS FROM CUTTINGS

During the next few weeks the stock of many desirable shrubs in the garden can be increased by taking cuttings of half ripened wood and inserting them in a sandy compost in a close frame with a mild bottom heat. Full details are given in this article when to proceed with this work together with a list of suitable subjects which should be tried.

DURING July and August many of our popular flowering trees and shrubs can be increased by inserting cuttings. Cuttings taken during the summer months, unlike those which are made in October—require the protection f a frame, hand-light or bell-glass. The ideal frame is one that has some form of bottom heat provided, sufficient to maintain a temperature of 65°–70° Fahr. The bottom of the frame can be made of a large slate stone placed about 6–9ins. above the hot-water pipes. Clean sand to the depth of 5ins. should be placed directly on to the slate, no drainage being necessary, and can be made firm by beating it down when in a moist condition.

Where only small quantities of several varieties are needed, and a frame such as that described above is not available, the cuttings can be inserted in pots, those having a diameter of 5ins. being a convenient size. First, half fill the pots with drainage of old broken pots, etc., and cover with a layer of fibrous loam or dried leaves to prevent the sand from choking the drainage. The pots may then be filled with sand and made level, and firmed by thoroughly saturating the sand and then tapping the pots on a bench or floor. The cuttings can then be inserted. Those placed near the rim usually root better than those in the centre of the pot. The pots can then be stood in a warm frame or hand-light in a greenhouse, or, failing this, in an ordinary cold frame or hand-light outside.

Hand-lights and bell-glasses may be utilised in a cutting bed made up of sand in a sheltered shady position outside; or the cuttings can be inserted in pots and plunged in ashes outside and then covered by the hand-lights or bell-glasses.

COMPOST FOR ROOTING.

The provision of a suitable compost in which to insert the cuttings is of great importance. Preference throughout the foregoing remarks has been given to pure sand; but it must be understood that sand contains no plant food, but is recommended for its great porosity, which ensures perfect drainage and aeration, thereby preventing all stagnation, so fatal to cuttings. These, when rooted in sand, should be potted as soon as they are large enough to handle. Where it is not possible to handle cuttings immediately they are rooted, a proportion of clean sifted loam or good oak or beech leaf-soil should be mixed with the sand to provide the young plants with the nourishment they will need on rooting; but experience will prove that many plants which can be raised in pure sand fail to strike root in a satisfactory way in a mixture of sand and loam or leaf-soil.

Having provided suitable accommodation for inserting the cuttings, the next important step is the selection of the cuttings from the parent plant, and on this point the whole success of propagation hinges. In the list at the foot of these notes, details are given regarding each plant; but certain general rules govern the choice of wood for the making of cuttings.

Avoid thin, weak shoots, and also vigorous, sappy growths; in preference, select medium sized healthy side shoots, and, if a heel of older wood is advised, select short cuttings, so that it is not necessary to reduce the length of the cuttings by removing the growing point. This applies particularly to cuttings of trees. Make each cutting carefully with a sharp knife just below a joint or node; the cut surface must be quite smooth and not ragged in any way.

DEPTH TO INSERT CUTTINGS.

The depth to insert cuttings is a point about which much doubt exists. A good general rule to follow is to insert the cuttings at a sufficient depth to keep them upright and firm in the compost. The use of a dibber for inserting cuttings of most woody plants is practically unnecessary, as they can be pressed into the compost with the forefinger and thumb. After inserting, water overhead with a can having a fine rose; this will settle the particles of sand around the base of the cutting and provide all the firming required. Subsequent watering must be carefully attended to. Sand frames during bright weather will need watering at least twice a day; but if leaf-soil or loam is added to the sand, less watering is necessary, as drainage is slower. The temperature of the water used should be the same as that of the frame or hand-light in which the cuttings are inserted.

Shading is often overdone, but some form of shade is necessary on very bright days. The use of newspaper, or tiffany, which can be taken off when not needed, in preference to putting on a permanent shading, is recommended.

Cleanliness is essential, and dead cuttings, leaves, etc., should be removed daily; but do not attempt removing leaves which have not been cast off by the cuttings. A very sharp-pointed bamboo stick is an ideal tool for picking out the leaves which drop off.

AFTER-TREATMENT: POTTING ON THE CUTTINGS.

When it is certain that a good percentage of the cuttings have rooted, they may be potted. Care is needed to avoid breaking off the young delicate roots when lifting them from a cutting frame or bed; a small trowel or a thin flat piece of wood should be used. Those inserted in pots are more easily turned out by holding the pots upside down and tapping them against the bench.

The compost used for the first potting should contain a good proportion of sand or grit to keep it open, so that no undue check is suffered by the cuttings. Do not over-pot, but place the cuttings in as small a pot as will conveniently take them; a useful size is one having a diameter of 2½ins. to 3½ins. Potting should be firmly done, and care taken to avoid bruising or shaking off the young roots. It is better to prepare a few cuttings for potting up than to expose a large quantity to the dry atmosphere at one time. After potting, the young plants should be placed in a closed frame having a similar temperature to that in which they were rooted, and watered. They should be kept syringed during bright weather, and, when they have become established and developed a good root action, may be given air and eventually stood outside, ready for planting, or placed in a cold frame for the winter.

When a sand frame has been cleared of all cuttings, and before inserting a new lot, the whole frame and the sand will benefit by watering with a solution of permanganate of potash and the frame left open for a few days.

LIST OF SHRUBS THAT MAY BE RAISED EASILY FROM CUTTINGS.

Berberis.—Such kinds as B. stenophylla are readily increased by inserting cuttings of young wood about 6ins. long with a heel of older wood in a compost of loam and sand in a cold frame in late August, and allowing them to remain until the following spring.

Buddleia.—Short cuttings of young side shoots with a slight heel will root readily if inserted in a warm or cold sand frame in July and August. The more vigorous kinds, such as B. variabilis, can also be propagated by inserting hard wood cuttings, 10–12ins. long, with a heel, in an open border in October.

Ceanothus.—Cuttings of both the spring and late summer flowering varieties are best inserted in a warm sand frame in August. They should be about 4ins. long, and the spring-flowering kinds—*e.g.*, C. rigidus—made with a heel.

Cistus.—Cuttings about 3ins. long taken from the tips of the young branches in August should be inserted in a cold frame with sandy loam and left until spring, when they should be potted up.

Cotoneaster.—Cuttings 4–6ins. long of young wood with a slight heel should be inserted in very sandy loam in a cold frame in August and allowed to remain until the following spring.

Cytisus.—Most brooms may be increased by inserting cuttings of young wood 4ins. long with a heel made so that no pith is exposed, in very sandy soil in a cold unshaded frame in August and left until the following spring. Many genistas will respond to the same treatment.

Deutzia.—Readily increased by inserting cuttings of young wood, about 3–4ins. long, in a cold or warm sand frame in July.

Diervilla.—Cuttings of current year's wood, 4–6ins. long, inserted in a cold or warm sand frame in July and August, strike root readily.

Escallonia.—Cuttings of short side shoots made with a slight heel should be inserted in a cold or warm sand frame in July and August.

Forsythia.—Insert cuttings 4–6ins. long of the tips of the young branches in a cold or warm sand frame in July. Cuttings 12ins. long with a heel can also be inserted in an open border in October.

Hydrangea.—Cuttings 4–6ins. long of half-ripened wood should be inserted in a warm sand frame in late July and August.

Jasminum.—All jasmines are easily rooted from cuttings about 4–6ins. long of half-ripened wood inserted in a cold or warm sand frame in July and August.

Kerria japonica.—Cuttings about 4–6ins. long of the young shoots may be inserted during July and August in a sand frame; or old plants may be divided in early spring.

Olearia Haastii.—Easily increased by inserting cuttings of the side shoots about 4–6ins. long with a slight heel in a cold frame with sandy soil in August, and transplanting to the open ground the following spring.

Prunus.—Such as P. triloba flore pleno, subhirtella and its varieties, can be increased by inserting cuttings of the young side shoots, 3–4ins. long, with a heel, in a warm sand frame in July.

Rosmarinus.—Cuttings about 4ins. long of the young branches should be inserted in a cold frame in August.

Spiræa.—Most spiræas will strike root readily from young cuttings about 4ins. long, inserted in a cold or warm sand frame in July and August. Such kinds as S. japonica are better increased by division in spring.

Viburnum.—The common laurustinus can be easily raised by inserting cuttings about 4ins. long in a cold frame with sandy soil in late August and September, and transplanting to the open ground the following spring. Generally speaking, the other viburnums are best raised by inserting cuttings of current year's wood 4–6ins. long in a warm sand frame during July and August.

Veronica.—Cuttings of the tips of the young branches, 3–4ins. long, should be inserted in a cold frame with sandy soil in August, and transplanted in the open ground the following spring.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

IN addition to the reference in last week's notes to the propagation of chrysanthemums by striking the tops obtained in the process of pinching the plants, Mr. Alexander McAlpine, Tollcross, the raiser of Janet Wyper, Mary A. Houston, John McAlpine and other fine specimens of the early-flowering type, tells me of another system of increasing stocks which he has practised successfully. In the work of raising new varieties it is frequently found that some seedlings —of which Janet Wyper is an example—are very shy in the production of basal growths suitable for cuttings; but experience has proved that if young plants raised from cuttings earlie rin the year are put out in a sheltered situation by the last week of March or the first week in April, the shoots which are sent up make splendid cuttings, which root readily and make fine plants by midsummer. In this way he has been able to augment his depleted stocks and, in the event of the last batch being too late for flowering the same season they can always be used as stock plants. Necessity is truly the mother of invention.

Owing to the late season and the slow growth that is still being experienced by gardeners all over the country, the prospects of the July and early August flower shows are not very encouraging. The question of postponement has been discussed by several horticultural societies and, in the case of Elgin Exhibition, it has been decided that the annual show, originally fixed for August 10th and 11th, is to be put back to September 7th, which date, unfortunately, clashes with the opening of the Glasgow Show.

From time to time reference has been made to the promised appearance of a winter-flowering pansy or viola, which all lovers of these useful and pretty flowers would welcome as an acquisition; but neither the one nor the other has materialised, and there is still a clear field open for the enterprise of the enthusiast. Probably the nearest approach to the winter-flowering viola was exhibited at the last meeting of the Scottish Pansy and Viola Association, when a number submitted specimens of deep yellow viola which had bloomed continuously since January.

Summer outings arranged by horticultural societies are becoming very popular in Scotland and the large attendances may be taken as an indication that the members appreciate the social and educational value of these excursions. Their sphere of usefulness would, however, be increased if the outings were fixed later on in the season. May is too early to see much bloom in a Scottish garden, and this year June was also disappointing in that respect. Flowers, fruit and vegetables are at their best in August, but possibly the practical lessons to be learned at that season may not compensate for the interference caused by other holiday attractions.

On making a somewhat lengthy jougrney to Dupplin Castle, Perth, on July 9th, the members of Paisley Florists' Society were favoured by the weather, and the gardens and grounds were, naturally, seen to advantage in bright sunshine. Accompanied by Mr. Beatty, the visitors inspected the lovely gardens, where there is one of the finest collections of alpine plants to be seen in this country. Some fine examples were seen of Eritrichium nanum, Meconopsis Baileyi and M. Prattii, lewisias in variety, and the thousands of other alpines and shrubs were much admired; while attention was called to a very fine fern, Adiantum pedatum Klondyke variety, growing in a sheltered spot. The company were the guests of Lord Forteviot at tea, served in the gymnasium, and the remainder of the afternoon was spent among the flower borders, in the kitchen garden and the fruit houses, which contained a varied collection of grapes, melons, figs, tomatoes, etc.

As a variation to the customary lecture by some well known authority or expert, the July meeting of the Royal Caledonian Horticultural Society was reserved for the consideration of subjects of horticultural interest, and among those discussed by members were the causes of stone-splitting in peaches, strawberry disease, a comparison of the qualities of cauliflower and broccoli, and steam heating. There was a fine show of flowers and fruit, and the following awards were made: Messrs. Dobbie and Co., gold medal for six varieties of sweet peas, and silver medal for exhibit of delphiniums; and a cultural certificate to Mr. George Balmer for a dish of Jargonelle pears. Other exhibits consisted of gooseberries by Mr. F. Glass, Murrayfield; and sweet peas by Mr. Miller.

Invitations have been issued to members of the Glasgow and West of Scotland Horticultural Society to visit Messrs. Austen and McAslan's nurseries at Cathcart on the 23rd inst, for the purpose of inspecting the trials of 140 varieties of sweet peas which the firm are growing naturally and on the single stem principle. A great deal depends on the weather, and should a favourable spell be experienced prior to that date the large area devoted to roses should also provide an attractive show. Mossparк Horticultural Society are due on August 6th, when the flowers are expected to be at the height of their bloom.

Aluminium sulphurate is being tried as a fertiliser in one of our Scottish nurseries, and the results of the experiment will be of interest to gardeners generally and particularly to the exhibiting class. I understand that this product has been used with success in the south. ST. MUNGO.

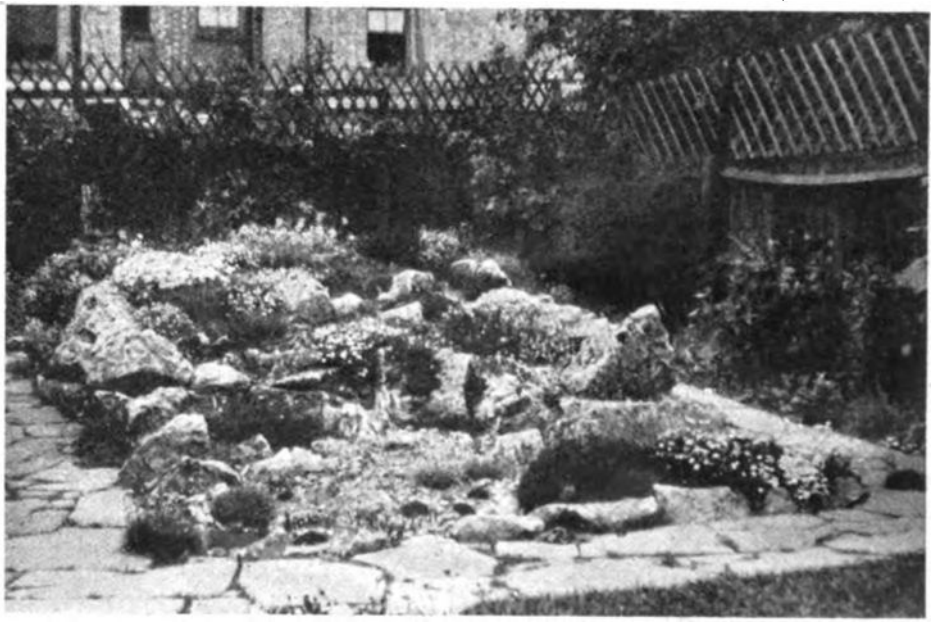
WHAT OUR READERS SAY

ALPINES IN SMALL GARDENS.

SIR,—Mr. Field-Marsham's letter on "Alpines in Small Gardens" in the July 2nd issue of THE GARDEN has prompted me to send you the enclosed photograph of my little rock garden which I have built in the lower half of a modest North London back garden. Before commencing I read up the subject thoroughly and that set me on the right road. In the autumn and winter of 1925–26 I dug out the heavy clay soil to a depth of about 2ft. and put in about four tons of broken road concrete as drainage. It was heavy work and it was often delayed by hard frost or heavy rains, but it was eventually completed. The weathered limestone rock I had sent down from Macclesfield, and by Easter of last year the rockery was built and only the crazy paving surrounding it remained to be laid. This latter job was more troublesome than I had anticipated, but at length the whole thing was completed and I had only to put in the plants and await results. You will notice that the design of the rockery provides for a dry wall on three sides and also for a small moraine.

A good many of the plants blossomed either in the summer or autumn of last year. Owing to the mild winter primroses were in flower by December, and these were followed in due course by snowdrops, scillas and crocuses, and then the whole garden began gradually to break into colour as the primulas, alyasum, arabis, aubrietias, Cheiranthus Allioni, helianthemums, etc., came into bloom.

As you will readily understand, the rock garden is only a tiny one, about 17ft. by 12ft., but it has more than recompensed me for all the labour the building of it entailed. It shows what can be done even in a small garden.—G. E. HARRIS, *East Finchley, N.2.*



AN ATTRACTIVE ROCK GARDEN MADE IN A TOWN GARDEN OF ONE OF OUR READERS.

All the plants are very happy and quite a bright display of colour is provided during the spring and summer months.

A NEW ST. JOHN'S WORT.

SIR,—A shrub well worth growing is Hypericum Forrestii. It is now in bloom and is, in my humble opinion, the handsomest of all the hypericums. My shrub was given me as a small plant in 1925, and is now a bush about 3ft. 6ins. high, 3ft. through and literally smothered in bloom. The individual flower is 2¼ins. in diameter, a pure buttercup yellow (so seldom met with in flowering shrubs), and much more refined than H. calycinum.

Another very fine evergreen shrub now in bloom is Solanum Lobelii. This I raised from seed in the spring of 1926, planted out the same autumn and it is now a well furnished plant 4ft. high. The foliage is handsome, each mature leaf being about 10ins. long, of a deep green colour, and the bloom is borne in clusters on a long stem from the axil of the leaves. The flower itself is pretty, the petals being incurved and "crinkly" of a bluish white colour. If only the shrubs will set fruit this year I shall be happy, for they are supposed to be as large as apricots and bright red.

Polygala myrtifolia is an evergreen shrub worthy of mention. It has an upright habit somewhat resembling the myrtle, after which, I suppose, it was named. It carries the usual light purple and white pea-shaped flower, which may be seen on it practically every month of the year except January and February. This was struck by me in 1924, and is now about 5ft. high. I prefer it to P. Dalmaisiana.

Leptodermis pilosa is, I fancy, an overrated shrub. In 1924 I was given some cuttings and told that it was a beautiful late-blooming shrub, but the only thing I can say in its favour is that its habit is neat, being very pyramidal, 6ft. high and only 3ft. through at the base. Besides being deciduous, the flowers are insignificant, somewhat resembling privet, only of a pale purple colour.

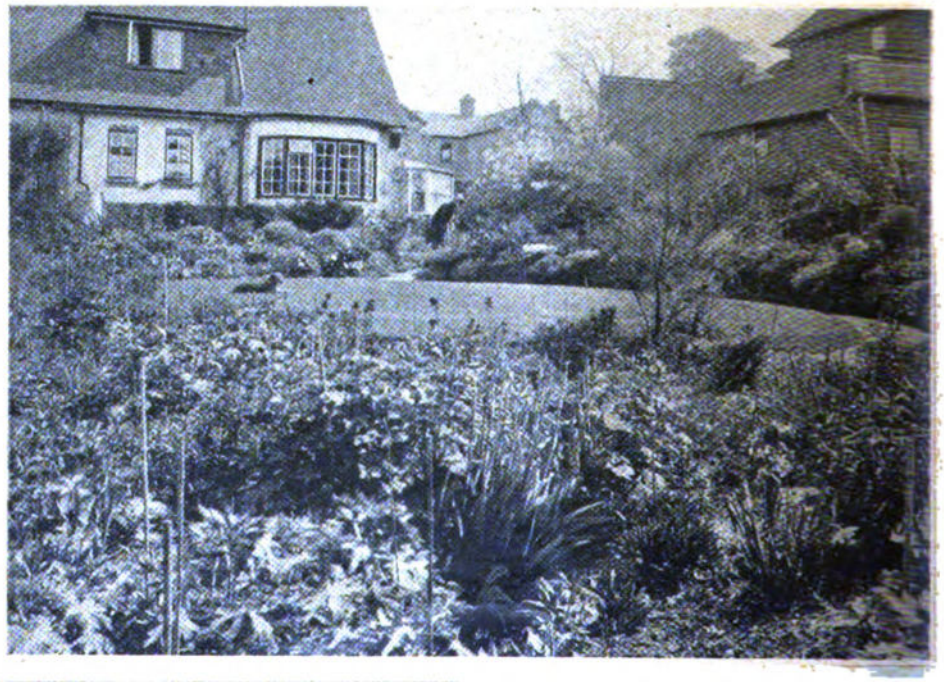
Finally, Euryops virgatæ has done wonderfully well this year. Masses of tiny yellow flowers have almost hidden its bright green heath-like foliage, and every visitor has been struck by the beauty of the shrub, whether in or out of bloom.—P. E. E. C., *Cornwall.*

MAKING PLANTS FLOWER.

SIR,—In your issue for March 12th you gave a very interesting article on making plants flower. This past spring I have had what to me seems an unusual experience. I have a raised bed in the front of the house facing south where for several years I have grown fairly good polyantha, good so far as colour and healthiness goes, but not good when one compares the size of the blooms—each individual bloom—with those one sees at the shows. Therefore I bethought me of a plan to increase the size and quality of the blooms, and so in the autumn, when I planted them in their blooming quarters, I mixed in the soil some burnt ash from the smother fire, and also a teaspoonful of bone meal to each root. I awaited with expectation a great improvement. There was an improvement in the colour and size of the leaves, and there were a great number of stalks which never developed one single perfect bloom. Each looked as if nibbled off. Is it probable that the treatment can have caused the blooms to be such tempting morsels that the birds ate them?—BUMPKIN.

OUR PHOTOGRAPHIC COMPETITION

The photographs illustrated this week are of a general nature, covering many different aspects of gardening. Now that the time is coming round for the making of new lawns and the renovation of old ones, the two accompanying illustrations of lawns are of particular interest. These indicate how a lawn can be made a pleasant setting for the garden and how it can be made to blend in with the general design. Many of our readers have, doubtless, photographs showing how the lawns have been placed in their garden and how they add beauty to the scheme. These, if published with personal notes, would be of assistance to those who are faced with the problem of laying out new lawns this coming autumn.



This photograph of my garden in one of London's outer suburbs was taken on April 20th of this year, and I think it shows what an attractive display may be had even early in the year. In the foreground is shown the herbaceous border in which are bulbs dotted between the perennials for early spring display. An oval lawn with a sunk path on one side and raised bed with a rockery bank makes a pleasant setting to the garden. Only common plants are planted in the rockery, but they provide fine masses of colour.

The Guinea Photograph, sent by MR. H. M. HARDING, *Carshalton, Surrey.*

The piece of ground shown is situated within eleven miles of London, and was, until two years ago, used as an allotment. It has now been transformed into a sunk garden which is turfed and beds are cut out for bush roses. The dry wall is 18ins. high and is planted with many small alpines and helianthemums, aubrietias, etc. Level with the top of the wall is a path and wide herbaceous borders backed by pillar roses and Penzance briars. At the bottom is just seen the rock garden planted with dwarf Japanese shrubs and choice alpines. MISS L. ROBERTS, *Chislehurst.* Award of 5s.

Digitized by Google

This photograph, taken last month, serves to show the full beauty of Saxifraga pyramidalis with its graceful cascades of white blossom which light up an otherwise dull corner. The single rosettes of this attractive alpine are up to 9ins. in diameter and are decorative even when out of flower.—E. MILNE REDHEAD, *Cheltenham.* Award of 5s.

Perhaps this is an unusual illustration for your competition, but many a pest destroyer has been put on the market having nothing like the qualifications possessed by our pet tawny owl. His chosen headquarters are on a shelf in the potting shed. From the nestling stage he has been reared in the garden, and the assiduous trapping of mice for him has made them so scarce that the annual damage to the pea crop is practically nil this year.—HAROLD DEACON, *Norton-on-Tees.* Award of 5s.

This specimen of Clematis Henryi was planted in November, 1925. In one year it reached the top of the porch as shown, and it has flowered splendidly both this year and last. The flowers are most beautiful, each measuring from 6–8ins. across. The aspect is due south and the plant has been given very generous treatment, which it well repays.—G. W. RUSHTON, *Norwich.* Award of 5s.

This rock wall is now three years old, and made entirely by myself of old bricks and paving stones. This spring it was very attractive with its masses of aubrietia in various shades, candytuft, alyssum and thymes. Dianthus and gentians follow on this early spring display and prolong its beauty.—MRS. DUFF, *Forest Hill, S.E.*23. Award of 5s.

This photograph illustrates how a rockery can be made to lend beauty to the entrance path to the house. Many varieties of aubrietias have been planted, and all the stonework is covered with Arenaria balearica. Rock roses, bushes of cotton lavender, various saxifrages and hardy primulas add to the display. There are three fine specimens of Japanese maples planted on the right which look very well in autumn with their rich colour.—MRS. G. W. DRABBLE, *Walton-on-Thames.* Award of 5s.

THE FRUIT AND KITCHEN GARDEN

How to Help on the Vegetables.

I BELIEVE in rendering all the help that can possibly be given to vegetables, and not leaving them to take care of themselves, as is so often the case. It is surprising how the simple process of applying artificial manures in small doses frequently throughout the season of growth, especially when about midway or nearing fruiting or swelling of the root, improves the yield.

Peas, for example. You can get a wonderful crop of green peas by dissolving half an ounce of soda in a gallon of water and going along both sides of the row at intervals of a couple of weeks or so. First of all, though, it is best to give the peas one thorough soaking of clear water as soon as they come into bloom and then get along with the manure water.

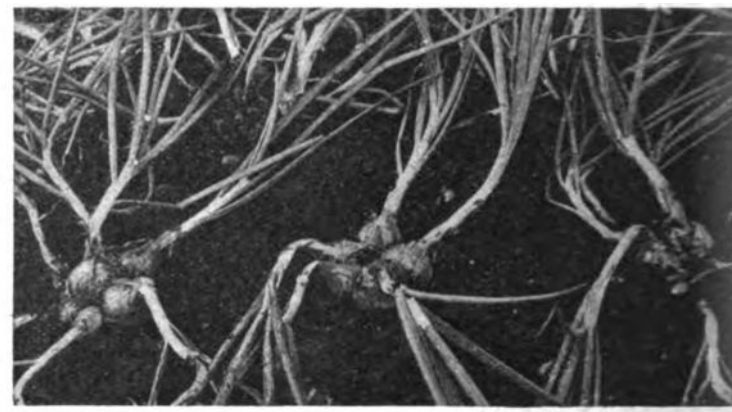
Nitrate of soda is also a good stimulant for onions, and will help them to make vigorous growth without being in too much of a hurry to run to seed. An application of a can of water in which some nitrate of soda has been dissolved will have a beneficial effect on onions, especially in time of drought, and also when the bulbs are swelling in hot weather.

For greens, nitrate of soda is much used, but sulphate of ammonia is a good artificial for summer use. A great economy can be instituted if a watch is kept upon cabbages and savoys as they grow. As soon as the little heart begins to form immediately sprinkle just a pinch of either nitrate of soda or sulphate of ammonia around the plant, hoe it in, and, if the ground is dry, give a good soaking. The cabbage so treated will hurry up in its heart formation in advance of the rest, and so cabbages can be had ready to cut in turn, one after the other, without all of them coming into use at once, and so getting spoilt.

To obtain that sweet nutty flavour in celery, it is not necessary to use a large quantity of rank manure in the trenches—a little will do; rather, sprinkle a handful of steamed bone-meal and the same quantity of nitrate of soda to about each yard or so of trench, well dug into the top spit. Rank manure produces huge, coarse celery; but the artificials will be the means of evolving solid well flavoured sticks that are worth eating. —A. H. NIGHTON.

Ripening Onions and Shallots.

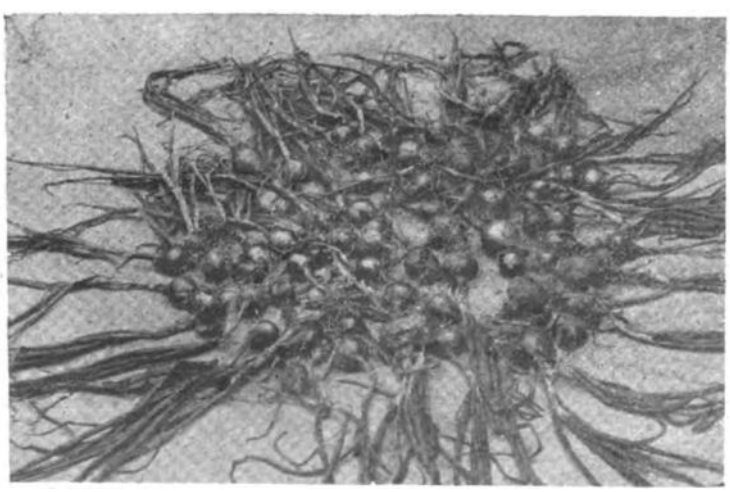
IN order that onions and shallots may "keep" well it is most essential that they be ripened properly. The ripening process really begins just now. Soil is hoed or forked away from the bulbs in order to expose them fully to sun and air, feeding ceases and the roots are loosened. When the foliage yellows further in the case of shallots or a month later in the case of onions, pull the plants up and let them lie exposed to the weather. Gather them on a dry day in the sieve and shake them so as to remove most of the soil. They now are placed in a spot where sunshine can complete the process—a mat, the roof of the outhouse, a net supported on poles, etc. When the weather is bad, cover them up or take them inside. It is a good plan, even after this, to continue the process for a further period by tying the bulbs up in bunches, hanging them in net bags or weaving them into ropes. Cured and dried in this way and stored in a cool airy place, onions and shallots will keep in perfect condition until next summer, if necessary.—H. A.



THE RIPENING OF THE BULBS MAY BE ASSISTED BY BENDING DOWN THE GROWTHS AND REMOVING THE SOIL FROM THE BASE.

Sowing Winter Spinach.

ALTHOUGH it is not too late, in some districts, to make a further sowing of the round or summer spinach, most growers like to make their first sowing of the prickly or winter sort about the end of July. The main sowing, however, may be made about the middle of August. Rake over a small area already cleared of some early crop, draw out shallow drills a foot apart and, if the ground is dry, water well. Sow the seed thinly thin out any tufts when the seedlings come up, and finally thin out to some 4ins. Thin out further from time to time, using the thinnings in the kitchen. In order that supplies may last as long into the winter as possible, see that some sowings at least are made in a porous and well drained place where the plants will be sheltered and protected from cold winds and beating, chilly rain. In cold districts and in the north, a little protection is required; spruce twigs usually do very well, or a board on edge along one side. Growers who live in a kindlier district than ours may sow as late as the first week in September. Carter's Giant-leaved is a fine bulky cropper which does well even up here; but the old prickly variety, the type, is always hardiest. LANARKSHIRE.



SPREAD THE BULBS OUT IN A SUNNY PLACE BEFORE STORING.

Perennial Broccoli.

DURING the last few years perennial broccoli have come on to the market, and readers must not overlook their merits. Taking as an example the Nine Star variety, I may inform them that, given good cultivation, the plants will give first-class results. On an average six to nine fair-sized heads of good quality are produced by each plant, and very likely a varying number, but roughly as many again, of small heads excellent for cooking in every way. The plants are raised from seed sown at once, or plants can be obtained from certain seedsmen (Dobbie's, Crisp's, etc.). These plants are then planted out in good ground and planted, like all the broccoli, firmly. One point which must be noted is that they are all the better for ample space, so that growers may plant now alternately with cauliflower, the latter being removed in good time to give the former the space they desire, *i.e.*, some 30ins. to 33ins. When the plants approach maturity feed them. Either apply a mulch of manure or sprinkle artificials and hoe them up round the roots or give liquids copiously. Next summer rake away the soil and throw fresh rich soil round them, again repeating the feeding in due course. My experience shows that it is a wise plan to bring on new stock and to discard old plants showing signs of senile decay after three years or so.—CLYDESDALE.

Cauliflowers for the Autumn.

A JUDICIOUS choice of varieties as well as a succession of planting is required to ensure full supplies of this aristocratic vegetable right on into late autumn. First of all, there are the autumn varieties proper, like Autumn Giant, Autumn Mammoth and so on; these really require a long season of growth to be at their best, and plants ought to be *in situ* now or planted at once. The "all-round" kinds, like Matchless, Eclipse, Excelsior, All the Year Round, etc., are excellent for successive planting. Under normal conditions they will mature roughly in nine or ten weeks, and if a few are put in every fortnight the crop may be expected with almost similar regularity. Later in the summer, after early peas and potatoes, the "earlies" can be planted, like Early Gem, First Crop, Early London, Six Weeks, Erfurt and the like, to yield supplies six to eight weeks after planting. To complete the certainty I recommend the planting of a few broccoli. As the cook said, "you can't tell which is which when they get to table," so put in a few Walcheren or Michaelmas White—and call them cauliflower. All this will ensure full supplies almost till December. —H. H. A.

THE SWEET PEA SHOW

IN spite of all handicaps of unsuitable weather the skill and perseverance of the enthusiasts prevailed and it was a very beautiful annual show of the National Sweet Pea Society at the Royal Horticultural Hall Westminster, on July 7th and 8th last. We have seen rather more sweet peas at the hall on former occasions when the weather has been kinder, but the quality of the blooms on the present occasion surpassed all others. It is the aim of the exhibitor to be able to stage spikes with four large blooms evenly placed on a long, stiff, but slender stem, and this the majority succeeded in doing, while every now and then there was a spike with five lovely blooms set daintily on it.

The centre of the hall was occupied with the exhibits of decorated dinner-tables and occasional tables. The idea of those responsible for the arrangements was commendable. It seemed to be that the visitor shall first see the great decorative value of their special flower and then shall be shown how finely their members can grow these flowers.

An admirable idea, but it did not materialise, for, truth to tell, these decorative classes were mediocre, though the baskets, bowls and vases of sweet peas, set out at the end of the hall, were charmingly arranged.

From the artistic point of view it was the large trade groups that fascinated the visitor. The competition for the two handsome challenge cups is always very keen. Last year Messrs. Sutton and Sons won both the Eastbourne and the City of Bath Challenge Cups, but this year the City of Bath Cup was won by Messrs. Robert Bolton and Son, while Messrs. Dobbie and Co. will hold the Eastbourne Cup for the year. In these classes excellent displays were also made by Messrs. Sutton and Sons, Messrs. Ireland and Hitchcock, Messrs. Carter and Co., Messrs. E. W. King and Co., Mr. J. Stevenson and Mr. A. Blandford. The effect of the massed blooms of glowing sweet peas was most delightful. The principal varieties were Mrs. A. Searles (a vivid orange cerise with a golden glow, which won the gold medal at last year's novelty trials), Magnet, Mammoth, Gold Crest, Jessie, Miss California, Gleneagles, Pinkie, Royal Scot, Charming and Prince of Orange.

In the amateur classes there were many magnificent vases of sweet peas, and, while only Sir Randolf Baker, Bt., entered for the Sutton Cup, which he won outright for the third successive time, the competition in most of the other classes was very strong. There were five entries for the *Daily Mail* Cup, which was won by Dr. A. V. Boyall, Minehead, a fresh exhibitor at these shows, with a collection of such merit that it was selected by the special set of judges as being the best amateur exhibit in the Show, and a vase of Magnet was adjudged the best vase in the Show. As his partner is on holiday, Dr. Boyal could not come to the Show, but Mrs. Boyall brought them and arranged the successful vases herself. Two well known exhibitors of sweet peas—Major C. B. Krabbé of Reading and Mr. F. W. Franks of Tonbridge—were second and third respectively.

The Cory Cup class, which requires six vases of distinct varieties, is always very popular, and this year no fewer than eleven members entered. It was won by Mr. G. L. F. Cook of Hayes, Middlesex, who set up admirable spikes of sweet peas.

In the two classes for new seedling sweet peas not yet in commerce, Messrs. Robert Bolton and Son had the best three vases, and Messrs. Ireland and Hitchcock were first with one vase. They showed their beautiful novelty, Greta, which received an award of merit at last year's trials. Messrs. R. Bolton and Son had Elsie, Dora and Mrs. A. Searles.

The eleven colour classes for sweet peas of definite shades of colour are of great value to all lovers of the flower, and, while Mr. F. W. Franks won seven of the first prizes, these classes enabled the visitor to select the best varieties. The best were: Blue, Sapphire; cerise or cerise scarlet, Grenadier; pink, Hebe; lavender, Powerscourt; orange or orange scarlet, Colorado; and white, Model.

The District Classes were a little disappointing. A fresh class, for members growing their sweet peas in the London County Council area, had been arranged, but there was no competitor; nor were there any from Scotland or Ireland, and only one from the northern counties. In the last-named, Mr. J. H. Emmett was awarded the first prize for a splendid exhibit. The southern class was the best filled, and Mrs. Shirley Woolmer, Bracknell, Berks, was first with an admirable collection. Mr. F. Churchward, Newton Abbot, Devon, won the first prize in the western counties class.

Among the new classes the most interesting were those for members who had never before won a first prize at any of the Society's shows, and for those who may or may not employ a gardener, but who grow the sweet peas themselves. In these the competition was splendid. Mr. E. Smith of Cholsey was first in the former class, and Mr. H. W. Linington, Isle of Wight, was first in the latter.

The Novices' Division continues to attract large entries, and many really attractive exhibits were staged. Although the judges awarded additional prizes, many worthy vases were, perforce, unrewarded.

On the second day of the Show many members of the Society met at Reading to see the trials of novelty sweet peas which have been grown so splendidly by Messrs. Sutton and Sons for the Society. This year of one half each set has been grown naturally, and the other has been disbudded, so that the relative values of the varieties could be readily seen. Awards of merit were given to a glowing orange cerise variety sent by Messrs. E. W. King and Co. (which was also reserved for the gold medal) and to The Prince, a deep crimson variety, much like an improved Sybil Henshaw, sent by Messrs. Ireland and Hitchcock. Although they did not gain awards, there were several varieties of great garden value. No. 2, from Messrs. Robert Bolton, is a desirable blue of medium tone. No. 81, from Messrs. Atlee Burpee and Co., is a most delightful pale salmon-coloured variety. Pinkie, a new variety from Messrs. C. C. Morse and Co., is a valuable sweet pea in shades of pink. Sunkist, from the last-named firm, may be termed a Youth with a cream ground, and, although it has been shown splendidly by Messrs. Dobbie and Co. at the R.H.S. Hall, it does not appear to do so well out of doors as when grown under glass. Two very useful purple varieties were sent by Messrs. E. W. King and Co. Messrs. Sutton and Sons most generously entertained the members to lunch and to tea, and, after having inspected their own trials, many members of the Society took advantage of the opportunity of visiting the varied and excellent general trials of Messrs. Sutton and Sons.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints (which should not exceed 150 words in length) is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

Replacing Old Helianthemums.

After a few years the helianthemums, though perhaps still flowering freely, get ragged in growth and lose the level appearance that shows the blossoms most effectively. They seed, of course, very freely, but the seedlings are rather difficult to move safely and their colouring is always doubtful.

By far the safer way of replacing the old plants is to cut off a well shaped branch just below a fork and as soon as the plant is dug up, put the branch into the same ground, first filling the hole with water. It will root immediately and the following season you will have a good sized plant flowering freely and, of course, true to colour.

Now that the flowering season is over, it is well to provide a new stock of these invaluable plants. All that is necessary is to take a good sized cutting and put it where you want it to grow. No plants strike more easily and cuttings sent by post to friends, if placed for an hour in water on arrival, will be just as satisfactory.—G. H.

Present Treatment of Strawberries

Few people realise that the time of the year at which strawberry plants make most of their growth is in the months of July and August, so that, after the fruits have been picked, the beds should receive a thorough cleaning and hoeing between the plants, and in order to encourage root growth, a little soil should be drawn up around the crowns of the plants, especially those of one year old plants, where heavy rains have washed it from around the crowns. This earthing up also acts as a preventive against the disease known as red plant.—M. H. G.

Home-Made Bird Bath.

The only materials necessary are a small quantity of cement, an earthenware saucer, such as is used to stand large flower pots on, an ornamental piece of tree trunk about 2½ft. long, preferably oak and stripped of bark, and a little cement-coloured paint. Select the spot where the bath is to stand and plant the tree trunk in the ground to a depth of about 1ft., previously tarring the end, if possible, in order to preserve the wood. Give the portion above ground a coat of paint. Next give the earthenware saucer a coating of cement, smearing it on in a rough fashion, as the result is more artistic. When quite dry, fill with water and place upon the top of the tree trunk stand. Plant clusters of flowers at the foot of the bird bath as this gives it a softer and prettier appearance.—J. A.

Hints on Chrysanthemums.

The leaf miner when dry weather sets in spoil many chrysanthemum leaves and are difficult to eradicate when once established. In this case prevention is better than cure, secured by syringing occasionally with "Abol" or quassia and soft soap solution, and picking off and burning all damaged leaves. Whenever aphis is seen, damp the foliage and sprinkle tobacco powder in the tops; it is better to do the whole lot to prevent the pest getting a hold. Earwigs give much trouble in a dry season; these must be caught and can be trapped by hanging bean or other hollow stalks (I use polygonum stems), by a piece of twine about a foot long, going over the plants twice a week blowing them into a tin of water and paraffin; this solution can be used the whole season; a large batch can be blown out in a few minutes.—G. W.

OUR SERVICE BUREAU

Blight on the Foliage of Apple Trees.

We have a splendid crop of apples this year, but, unfortunately, there is a sort of blight in some of the trees. I am enclosing three of the leaves and shall be glad if you can instruct me how to deal with this trouble.—A. J., Langley.

In reply to your enquiry, the blight on the apple tree foliage sent for our inspection is called the rosy apple aphis. Trees infested with this should now be sprayed with a strong contact wash, such as nicotine wash or "Katakilla," the spray being applied forcibly and very thoroughly. In January next the trees should receive a spraying with a tar distillate wash, such as "Mortegg" or "Carbokrimp," to prevent a recurrence of the trouble next year. Unless this particular blight is very widespread over the trees, there is little danger of it spoiling the development of the fruit, though, of course, it has a decidedly weakening effect upon the trees, especially if left unchecked. We trust that you will, by these methods, be able to rid your trees of this pest.

Leaf-Spot on Tomatoes.

Can you tell me what is wrong with my tomato plants, and what I can do for them? The plants are in a small greenhouse, and all the plants are affected.—M. I., Edinburgh.

The tomato leaves sent for our inspection show early signs of leaf-spot, due to a fungus, Cladosporum fulvum. We advise you to spray the plants with Bordeaux mixture and look to ventilation. There is probably too much moisture in the house and too little ventilation.

Insect Pests on Buddleias.

I am enclosing a leaf of a buddleia tree which has been attacked by some form of pest but which is not discernible. Would you kindly inform me what it is, and what is the best remedy I can apply, as the pest is very rapidly spreading.—D. S. P., Hurlingham.

The buddleia leaves have been attacked by weevils, probably the clay-coloured or raspberry and the nut-leaf weevils. They are nocturnal feeders, so that their presence is often overlooked until the damage is done. The best remedy is to spray with lead arsenate, at the rate of 1lb. paste to 12–15 gallons of water. Care should be taken to keep the liquid agitated to prevent precipitation of the lead arsenate. Apply through a fine nozzle to avoid drenching, as it should be the aim of the operator to produce an even film of poison over the whole plant. Many weevils may be captured by placing pieces of rolled-up sacking around the attacked plants, for they will seek such quarters during the daytime.

Remedies for the Leaf-Rolling Saw-fly.

What is wrong with the rose branch that I have forwarded, the leaves of which are rolled up? It started last year on a newly planted rose, Viscountess Folkestone, and this year has spread to others on the same rose bed. They are not so badly attacked as this particular one. Would you kindly tell me what is the cause of it, and if there is any remedy. There are about 100 roses in the bed, and many are tainted with it this year.—H. D., Oswestry.

The roses sent for inspection are attacked by the leaf-rolling saw-fly, Blennocampa pusilla. We advise you to hand-pick the rolled leaves, in which are to be found the larvæ, and burn them. Spray soon after the buds open with paraffin emulsion, to act as a deterrent to egg-laying by the female saw-flies. Remove the top 4ins. of soil during December and bury deeply in order to kill the pupæ, and replace with fresh soil. This pest is often introduced into gardens on new roses. It is a good plan to wash all roots free from soil before planting.

Insect Pest on Runner Beans.

I am enclosing a couple of leaves off my runner beans which are being eaten by something. Can you please tell me the cause of the trouble and the remedy? I am troubled with ants in parts of the garden, but I do not think they are responsible in this case for the damage. Do you think so? I have found tiny green insects on the under side of some of the leaves, and suspect these are the cause of the attack. What measures do you suggest I should take? The plants themselves seem healthy enough, and are growing sturdily.—H. D., Sutton.

In reply to your enquiry, the leaves of your runner beans are not badly eaten. Ants do not eat them, but burrow down near the stems. The leaves sent are slightly eaten by slugs or small shell snails. Scatter some dry soot, or lime, on the soil near the rows, but not on the plants. We do not think you need worry about the condition of the plants.

Culture of Hydrangea hortensis.

I was very interested in the article appearing in the June 11th issue on the treatment of hydrangeas after flowering. I have for two seasons grown a collection of the newer varieties with unsatisfactory results; the plants proving anything but free-flowering. The larger percentage of growths, though strong, failing to terminate in a flower truss. This trouble is apparent both in specimen plants and those grown for flowering in 5in. pots (single truss). I should be very grateful for your opinion, especially in regard to the following points: (1) A large number of my plants produce lateral growths from the lowest portions of their stems, also basal suckers; when these occur before the flowering period, being apparently useless, could they not be removed with advantage to the main flowering growths? (2) The plants are potted in a compost of loam, leaf-mould, peat and coarse sand, no manure whatever is added to the compost, and the plants are not fed until the flower trusses become visible. This is in accordance with the strict instructions given me when I purchased the plants. Though I have followed this advice, I must admit it seems that the plants ought to receive some form of feeding long before the flower trusses become visible, the pots being well filled with roots quite early in the season?—H. L. B., Maidenhead.

The best flower heads are produced at the ends of the shoots of the previous year. Hence every effort must be made to preserve unharmed the tips of the shoots through the winter. The lateral side growths and basal growths which interfere with the main shoots should certainly be thinned, if not all removed. In the case of the 5in. pots with a single truss, all side shoots must be removed. Old decayed manure should certainly be added to the potting compost, and the plants given liquid manure when growing freely, even before the flower heads are visible.

Striking Cuttings of Azalea rosæflora.

I have in my rock garden a very beautiful Azalea rosæflora and should much like to increase my stock. I should be glad if you could let me know whether the plant is easily raised from cuttings and the best method of doing so.—D. M., Eltham.

Cuttings of Azalea rosæflora root fairly readily in July. Pull them away with a gentle downward pull from the parent plant, leaving a very thin skin or "heel" at t base. Insert in a pot of sandy peat, cover wi a bell glass and place in a greenhouse, pr pagating case or cold frame, from which a is excluded, except for one hour daily.

SOCIETY NOTES

The Windsor Rose Show.

THE Windsor, Eton and District Ro and Horticultural Society is fortunat in having as patrons the member of the Royal family and in being allowed t hold its shows in the grounds of Windso Castle.

On July 9th was held the most successfu Show for at least the past twenty-five years Roses were, of course, the chief feature and these were shown splendidly. Messrs Frank Cant and Co. added to their many triumphs and made history at Windsor b winning the King's Cup for the fourth successive year. Their forty-eight varieties include Countess of Lonsdale, Gladys Holland, The General, Mabel Morse and Mrs. Henry Bowles. Messrs. B. R. Cant and Sons who were second, had the satisfaction o winning the first prize in the class for twelve varieties, three blooms of each with a magnificent exhibit. Their trios included Lemon Pillar, The Bell (a new hybrid tea of excellen shade and pale lemon colour with a flesh pink heart and sweet perfume), and Alice a fine deep rose hybrid tea variety.

Tea roses were not of such high quality and some of the blooms showed signs o the stress of recent weather; but the decorative roses were exceedingly beautiful. The best eighteen vases were set up by Messrs A. Warner and Sons. Mr. F. Spooner was a good second.

The amateurs' roses were admirable in the open classes. Dr. R. C. Turnbull, Colchester, won the Windsor Challenge Cup for the third successive time, and he had twenty-four particularly good blooms. The outstanding varieties were Avoca, Lady Inchiquin, The General and George Dickson. Mr. F. H. Fieldgate, the second prize winner, won first prizes in two classes for growers of limited numbers of plants, and Mr. W. E. Moore had, in Candeur Lyonnaise, the best hybrid perpetual and in Mrs. Foley Hobbs the best tea blooms in the amateurs' classes. The best hybrid tea was a specimen of Mrs. Henry Morse, shown by Mrs. Walter Legge.

Sweet peas generally were not quite up to the Windsor standard of quality, but Major C. B. Krabbé, Reading, won the Prince of Wales's Challenge Cup with twelve superb vases of Hawlmark Salmon, Powerscourt, Youth, Constance Hinton, Picture and other good varieties. Dr. R. C. Turnbull won the Aird Cup with an admirable collection of sweet peas which included vases of Mrs. H. T. Wright, Annie Ireland and Magnet.

The trade supported the Show finely and their exhibits contributed towards its success. Mr. J. C. Allgrove won Lady Carter's Challenge Cup with an excellent group of hardy border flowers, and also showed roses and sprays of flowering shrubs. Messrs. Waterer, Sons and Crisp had a very beautiful group of Japanese irises. Mr. William Yandell staged a large collection of violas and pansies. Hydrangeas and roses were grouped by Messrs. William Cutbush and Son. Mr. Charles Turner displayed miscellaneous plants. Messrs. S. Bide and Sons had a large collection of sweet peas; while roses were arranged by Mr. J. H. Pemberton, Messrs. Wood and Ingram, Messrs W. E. B. Archer and Daughter, and Messrs. Lund Brothers. Messrs. Allwood Brothers had a large collection of carnations, and Messrs Hewitts, Limited, staged very good delphiniums.

GARDEN
THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2904 Saturday, July 30th, 1927 Price TWOPENCE

THE accompanying illustration is of that magnificent climber, the Flame Flower, or Tropæolum speciosum There is no climbing plant that can compare with this for brilliance or beauty of colouring. It is a climber which requires support, but it should never be trained It is best left to its own devices and does well if allowed to climb up a hedge or ramble at will over a bush It looks particularly effective when draping a yew hedge. It grows readily in all gardens in Scotland, especially on the west coast, while it will also flourish in gardens in the south. While it it is perennial in habit, the growths die down every year, and are replaced by fresh shoots in spring. As it is supplied in pots, it may be planted at any time of year, but preferably in autumn or spring. Amateurs should give it a trial by growing it through a rambler rose that is draping an arch or furnishing the house wall. It provides a vivid splash of colour.

THE GARDEN

VOL. XCI.—No. 2904. JULY 30, 1927. PRICE TWOPENCE

THE TREATMENT OF SUCCULENTS

WE are sometimes asked by readers to give details about the treatment that should be meted out to those ttractive small members of the great tribe f succulents that are becoming increasingly opular for growing in ordinary dwelling-ouses in towns. At present their names re only known by a few enthusiasts, owing o the lack of a moderate-priced book written n the subject in English. In Germany hese plants are exceedingly popular and everal excellent books have been written bout them. It will suffice at the moment o say that forms of the following genera re suitable for pot culture in an ordinary dwelling-house—haworthia, stapelia, echinocactus, opuntia, mamillaria and pilocereus.

It may be said that these plants are grotesque in appearance, but none the less there are few who will not call them attractive at all seasons of the year, while some of them bear lovely flowers. It may be as well to mention that the flowers of the stapelias are so lovely that one may be tempted to smell them. It is better if this is done at a distance, for the concentrated odour is offensive. The great advantage of these plants is that they prefer the least possible attention; in fact, their death is always due to too much of the ordinary kindnesses that we are accustomed to give other plants in the house. Their main requirements are adequate drainage, ample sun if they are to flower and not too much water. A good compost can be made of two-fifths fine loam, one-fifth sand, one-fifth grit and one-fifth finely broken crocks. Broken crocks should be placed at the bottom of the pot and the soil packed tightly round the plant. Repotting should be done every third year. The greatest danger is rotting of the collar of the plants when they are first exposed to the air, and so watering should be done either by dipping the pots in water or by watering on the surface and tilting the pots so that the stem is moistened as little as possible. During the growing season, from April–July, they can be watered in moderation once a week, from July–October once a fortnight, and during the winter months certainly not oftener than once a month, unless the room in which they are grown is kept very hot and very dry. Although they will grow in rooms that may be practically sunless, they will not flower without sun to ripen them. You cannot give them too much sun, for remember that most of them live in dry desert country. Attractive groups may be planted together in large bowls, but these should be of unglazed earthenware and a drainage hole is essential. Little boulders can be placed on the surface and your cacti planted among them, making a very natural effect. It is as well in these large planted bowls to leave a hollow either in the middle or at the side—the excavated earth can be heaped into a mound elsewhere—and then the bowl can be watered by watering the hollow, which will prevent the moisture from reaching the collars of the plants. It is to be hoped that these easy and attractive plants will in time gain the popularity that they deserve.

This Week's Work

For Gardens in the South and Midlands.

Plant irises.

Sow cyclamen in pans and place in a cool greenhouse.

Top-dress chrysanthemums and tomatoes in pots.

Tie in shoots of Morello cherries and espalier-trained fruit trees.

Propagate rock plants by inserting cuttings in a frame containing sandy soil.

Sow spring cabbage.

Stake Michaelmas daisies, border chrysanthemums and dahlias.

Lift shallots when mature.

The Modern Dahlia.

BETWEEN the old-time dahlia and the modern types there is so great a difference that those who have not kept pace with the improved varieties of this popular flower do not always recognise them as belonging to the same family. The stiff, formal shows and fancies, and the cactus varieties which, like blushing beauties, shyly hung their heads have largely given place to graceful flowers in many shapes and colours, freely produced and carried well above the foliage on strong, wiry stems. Their adaptability for garden decoration and for cutting is evident at a glance, and that they are gaining favour rapidly is easily understood.

In order to give the public an opportunity of becoming acquainted with the various sections of the dahlia, the National Dahlia Society has arranged with the Flower Show and the Parks Committees of the Southport Corporation to devote a large border to them in the South Marine Park, adjoining the Southport Promenade. This border will be about 200ft. long by 15ft. wide, and will contain a representative collection, embracing the large decorative, small decorative, large peony, small peony or charm, star, collarette, single, Mignon, pompon, cactus, and also the show sections. Altogether there are some seven hundred and fifty plants of the best varieties in cultivation, contributed by eleven of the leading dahlia firms. For purposes of comparison, plants of the original species from which all have been evolved, will be grown alongside them, these being sent by Mr. Thomas Hay, V.M.H., M.V.O.

The different sections will be planted in separate blocks, each distinctly labelled, and with due regard to the varying heights and colours. It will thus give the border both an educational and a decorative character. From July or August until frost it will be a great attraction, and during the period of the Southport Flower Show (August 24th, 25th and 26th), will be seen by many thousands of visitors, who will be able to judge for themselves of the "infinite variety" of the modern dahlia.

This is the first time an experimental display of this nature has been made in a public park, though some thirty-five thousand dahlias are grown annually in the Southport parks.

This Week's Work

For Gardens in Scotland and the North.

Sow winter onions of the Tripoli type.

Spray roses as a preventive of mildew.

Remove all blooms of show pansies and violas ten days before exhibiting.

Sow Beauty of Nice stocks for winter flowering.

Propagate rock garden plants by means of cuttings.

Feed exhibition onions with liquid manure.

Pinch tomato plants growing in a cold greenhouse when four trusses are formed.

Stop feeding roses at end of July.

Give dahlias in bloom liberal applications of liquid manure.

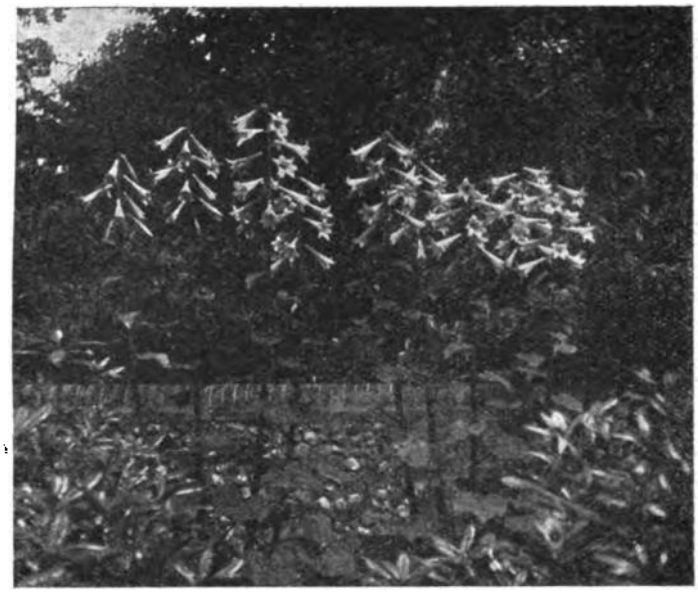
LILIES FOR EVERY GARDEN—II

SUN-LOVING LILIES.

THE second group for purposes of cultivation comprises the species that require an addition of peat to the loam and leaf-mould, as far as soil is concerned, while in the matter of exposure they will succeed in a position that is fully exposed to the sun, especially in parts of Scotland where the climate is moist and the sky frequently clouded. On the whole, however, they seem to thrive best in a spot which is shaded from the sun's rays during some part of the day. Thus they can be grown in a hardy flower border where there are trees or tall shrubs, etc., at no great distance, and where a little peat and leaf-mould are added to the soil, while on lawns and even in conjunction with bedding plants, they may be treated in the same way. Probably the ideal situation, however, for most of this group is to be found on the outskirts of a shrubbery.



A FINE CLUMP OF LILIUM GIGANTEUM.

Here all the most essential conditions will be fulfilled, provided that a spot be chosen which is only partially shaded, while the lilies will be shown to their best advantage and the beauty of the bed of shrubs in which they are planted will be prolonged and increased.

For instance, if the varieties of LL. auratum and speciosum, both of which are prominent members of this class, are planted in groups and drifts among azaleas of the mollis type, which have been set at a good distance apart so that none encroaches upon its neighbours, they will be at the height of their beauty in August and September when the beds might otherwise be dull.

For purity, grace and beauty combined, on the other hand, there are surely few, if any, hardy plants to rival L. speciosum, or lancifolium as it used to be called. The colour of the suffusions, spots and papillæ of the large, white, reflexed flowers varies from bright pink in the type to rose and crimson in such varieties as roseum, rubrum and melpomene, while album and Krætzeri are almost entirely of a pure snowy whiteness.

This is, of course, only one of the many effective combinations which may be planned — for instance, LL. Washingtonianum, Henryi and Hansoni may be used in the same way, while any of these species make very attractive groups by themselves.

L. Krameri is rather more difficult of culture than others of this group, but it is a very beautiful species and possessed a monopoly among lilies of a clear pink colour until the introduction of Lilium rubellum.

The smaller kinds, such as L. concolor and L. rubellum, are very useful on the edges of shrub beds or in any little corners that are not too deeply shaded. Care should be taken, however, not to plant them too near to anything that is very vigorous in growth, for they are quite dwarf and must not be allowed to be overrun or surrounded by coarse-growing shrubs, which would detract from the elegance of their habit and hide the beauty of their flowers. It is by no means easy to succeed with L. rubellum. Although it revels in a moist soil and partial shade, nevertheless it is most essential to provide thorough drainage for the bulbs in winter. Probably the best way to secure this is to plant them just above some thick root of a tree, choosing one which has no low branches and does not produce suckers at the base. The bulbs need only be 12ins. or 8ins. away from the bole, but should be set 18ins. below the surface of the soil.

Quite one of the most useful for this latter purpose is L. Martagon, which is also an excellent lily for the herbaceous border, as we have already seen. The deepest coloured variety of it is dalmaticum, which attains a height of 5ft. or 6ft. and bears masses of dark maroon flowers, while the white form, album, is even more beautiful.

Two other examples of this class will suffice, *i.e.*, L. Brownii and L. tenuifolium. As regards culture, the details advised for the first group may be applied to both this and the next one, while in the wild garden and with an undergrowth of shrubs the condition of the soil will be much moister and watering is not likely to be necessary.

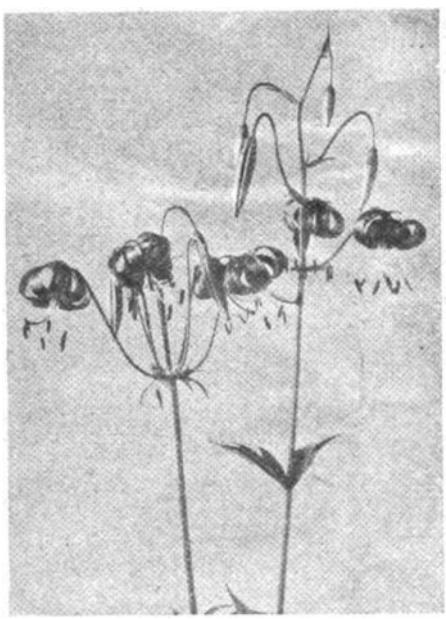
All the species mentioned above are stem-rooting with the exception of LL. Washingtonianum, Martagon and tenuifolium. The latter species, which is a charming little scarlet-flowered Turk's-cap lily, is well suited to the rock garden, and both this and L. Washingtonianum should be carefully looked after.

Much more robust is L. Brownii, with its beautiful white trumpet flowers heavily suffused with chocolate on the outside. The flowers are usually solitary on stems 2ft. to 3ft. high.

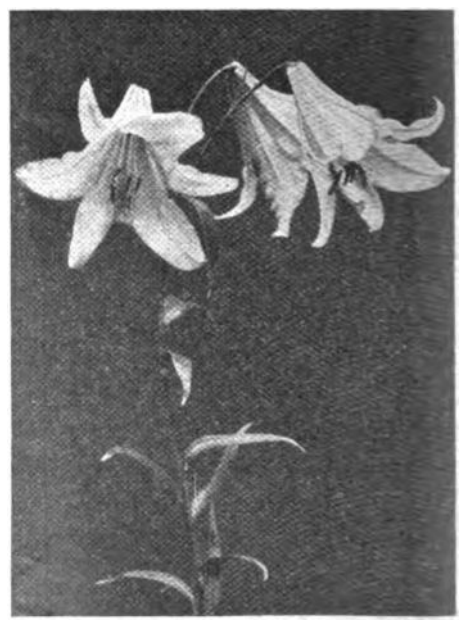
SPECIES FOR A SANDY PEATY SOIL.

Turning now to the third and last group, this consists of a few lilies which revel in a deep sandy peat soil and one that is naturally moist but not sodden—a soil that in the driest days of summer seems moist and cool on the surface. These, again, require shade during some part of the day, and may be planted in situations similar to those advised for the last group, only rather more shaded. Thus an ideal position is again to be found in a wood or wild garden where the soil is naturally peaty, while at the same time the shade must be by no means dense. If the original soil is almost pure peat, it should be deeply dug and have sand and leaf-mould and, if necessary, a small quantity of loam incorporated with it before planting. A waterlogged condition, of course, cannot be tolerated, and if such exists the site must be thoroughly drained, at least 2ft. of good soil being left. The nature of the soil and the undergrowth will then ensure moist conditions throughout the year. The shrubs among which the lilies are planted may be, as before, azaleas, dwarf rhododendron species, zenobias, kalmias, enkianthus, gaultherias, the smaller vacciniums, etc. Some of these are quite moderate in growth, while others may be kept in bounds by thin planting and the occasional use of the knife.

L. pardalinum, the panther lily of California, is one of the best of this class, being very hardy, a robust grower, and producing tall and graceful stems with often as many

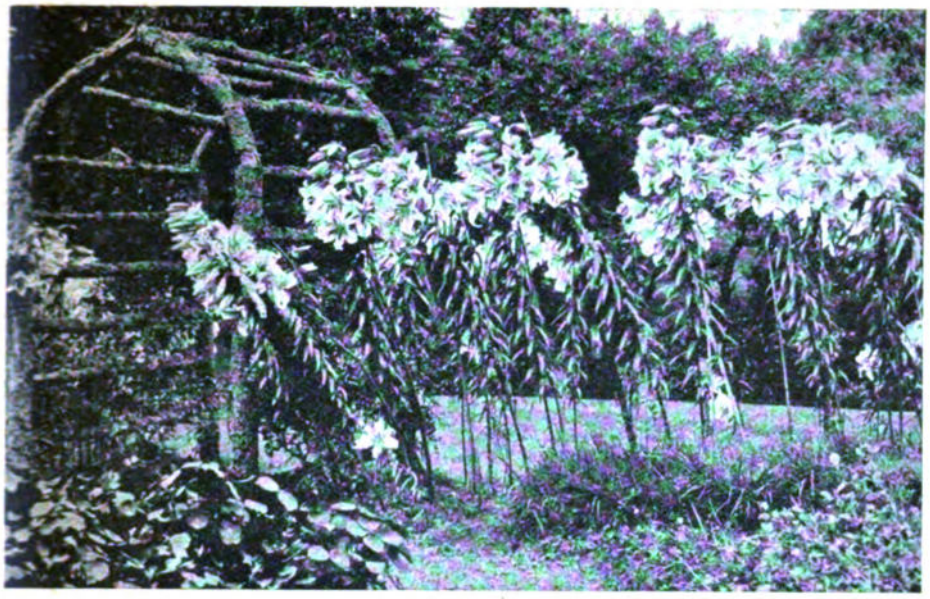


THE PANTHER LILY, L. PARDALINUM WITH BRIGHT RED FLOWERS.



THE WHITE TRUMPET FLOWERS OF LILIUM BROWNII.

Digitized by Google



A WELL FLOWERED GROUP OF THE HANDSOME LILIUM AURATUM, THE QUEEN OF LILIES. HERE IT IS GROWING AT THE EDGE OF A SHRUBBERY BORDER.

as twenty or thirty flowers on each. The flowers are large and the petals strongly recurved, bright red or scarlet in the type, with the lower parts orange spotted with red. Since the stems will reach 9ft. in height and are very slender, ample protection from wind should be afforded; but, on the other hand, the growths must have plenty of air and light around them and resent being too crowded by shrubs.

Liliums Grayi, superbum, Parryi and canadense are all American species, well suited to this form of culture. L. cordifolium, however, is a native of Japan. It is known as the heart-leaved lily, being similar in this respect to L. giganteum, though very much smaller.

L. giganteum itself comes from the Himalayas, and is the largest species known, for it will reach a height of 10ft. or 12ft., with huge hollow stems and enormous bulbs. The bulbs must become thoroughly established before they will throw up flowering stems, and should be planted in their permanent quarters three or four years before flower is expected. When flowering, the top of the bulb will be found to be level with the surface of the soil, but as the bulbs are gradually pushed upwards they should be buried about 4ins. below the surface when planting is done. The value of the Himalayan lily lies not so much in the beauty of the individual flowers as in the elegant stateliness of the general habit and the massive beauty of the whole plant. The habit of growth necessitates a change in situation from others of the same group, for were L. giganteum to be planted actually among shrubs, the lower part of the stem would be hidden and half the grace and beauty of the plant lost in consequence, so that it is only shown to best advantage when planted in a comparatively open space. F. R.

TRELLISED WALLS FOR CLIMBING PLANTS

THERE is something abhorrent about a bare house wall to most gardeners, who lose no time in planting some suitable plant which will, in due course, hide its ugliness. Although it is a well known fact that all climbing plants do better when trained on some support which projects from the wall, many gardeners still go to a great deal of trouble to nail in the growths with shreds. This is bad both for the plant and the wall.

On high walls it is an easy matter to fix galvanised eyes through which insulated wire is threaded and strained. The insulated wire can be purchased very cheaply, and does not damage the plant either by frost or wind. Unprotected wire will often do considerable damage during frosts at the points where growth touches the bare wire.

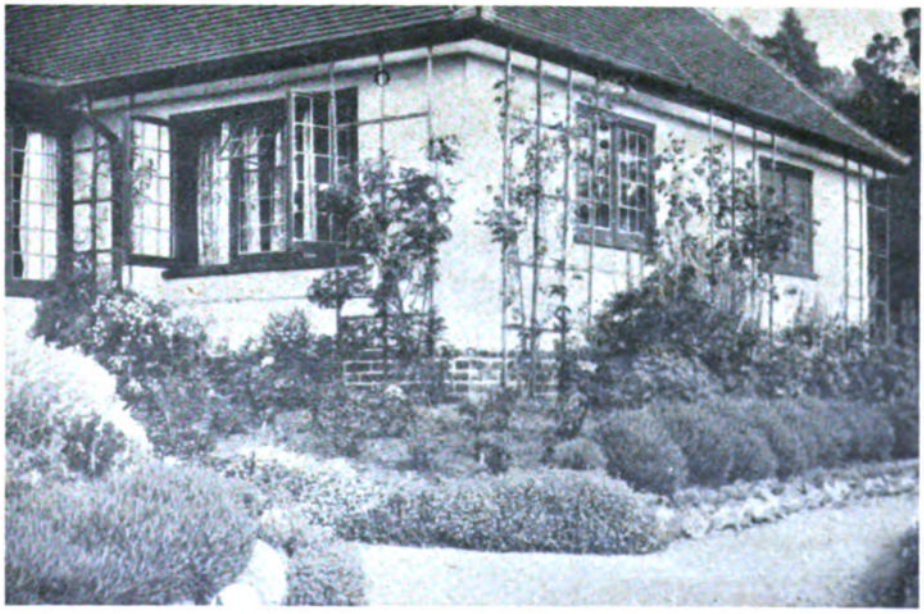
When a short wall has to be treated, such as is found in most of the modern bungalow dwellings, a square trellis serves admirably, and has the advantage of breaking up the wall space, while the plants are making their growth. In most cases such a trellis can be fixed by a galvanised nail or two driven into the eaves, the whole being rigidly held by sinking the ends into the soil. Such supports will stand a foot or so away from the wall, which makes the matter of training an easy task; the ends which enter the soil should, of course, be tarred to prevent rotting. If it is impossible to fix such a trellis to the woodwork of the eaves, the wall may be plugged, 6in. blocks or brackets being fixed to the plugs and the trellis fastened to these.

The advantage of such a trellis is seen when the house has to be decorated, it being a simple matter to untie the growths and lay them on the border until the work is completed. The square trellis can be purchased ready made, and if of oak will not rot for some years, either above or below the soil. Such trellis is, however, expensive, and a very good substitute can be obtained by constructing the trellis from builders' tile battens. Being of pine, they should be treated with one of the anti-rot preparations, which gives them a pleasing brown tone. As all plants have a strong objection to creosote in any form, the battens should be treated some time before any growths are tied to them.

The tiling battens can be purchased from any builder in a variety of lengths. They are about 1½ins. square and roughly cut, which enables the creosote to enter easily. These should be nailed together with small galvanised nails. Plain wire nails rust through in the course of time, and the trellis falls to pieces.

The squares of the trellis need not be very small, except when they form the supports for the side of a porch, when they may be 18ins. square. For ordinary wall use, 2ft. or 3ft. answer admirably. The necessary measurements having been obtained, the trellis may be constructed on any flat piece of ground; a lawn being particularly suitable. The ends should be first inserted into holes dug in the soil for their reception, the soil returned and rammed firm. The top is then nailed to the plugs or eaves.

Clematis, honeysuckle, roses and jasmine greatly appreciate such supports, which can also be adapted for placing round a porch or doorway; and can be made to give a living porch if one does not already exist. Two very suitable roses for such a porch covering are found in climbing Sunburst and climbing Lady Hillingdon. C. P.



A HOUSE WALL MADE ATTRACTIVE BY TREILLAGE AND SUITABLE CLIMBING PLANTS.

Digitized by Google

PLANTS FOR SHADY ROCKERIES

MANY enthusiastic gardeners — and especially those dwelling in towns — find the only space they have to spare for a rockery is in a shady part of the garden, and deterred, perhaps, by the unfavourable position, give up all idea of this desirable addition to the garden. For the comfort of these unfortunates, let it at once be said that many of our most charming rockery plants will thrive in shade—providing there be no actual drip from overhanging trees—while quite a number which are usually regarded as sun-loving plants will flower quite freely in, at any rate, semi-shade.

On the other hand, there are plants that flourish altogether too well under any conditions. The white woodruff, Asperula odorata, is a delightful plant for some situations; but once let its roots get a hold in rockwork and it will become an untamable pest. Helxine Solierolii, the Corsican nettle-moss, grown for its vivid green foliage, is another rampant grower in shade, but, fortunately, it is often severely cut by frost, though it is very unlikely that the whole plant will be destroyed. Periwinkles are also favourite plants for shaded rockwork, but they will inevitably smother all other occupants, while nothing short of taking down all the stones and digging out the periwinkle roots will serve to eradicate the pest. It is wise to speak carefully of these plant pests, for in some gardens they spread freely, and in others are even looked upon as difficult plants to grow; but the above three, with the addition, perhaps, of members of the corydalis family, are almost universal nuisances. Others that should be planted with care, or even omitted altogether, are acæna, Arenaria balearica, cotula, mentha, epilobium, the stronger-growing forget-me-nots (myosotis) and Meconopsis cambrica. The last two, however, spread entirely by means of self-sown seed, and are, of course, much more easily kept in check than those monsters which creep by underground stems, and so pop up in all sorts of undesirable positions, and at that have their roots too deep to be easily removed. However, let us get on to a more agreeable matter—those plants that can and should be grown in the shaded rockery.

ONE OF THE ATTRACTIVE FORMS OF THE WOOD ANEMONE THAT WILL FLOURISH IN A SHADY POSITION.
This is variety Alleni with pale blue blooms.

Dwarf campanulas include among their numbers some of the showiest and most easily grown of all rockery plants, and, as they flower at a time when the earlier alpines are going over, they must be accounted of special value. Some of the finest are Portenschlagiana, with drooping violet flowers in profusion; G. F. Wilson, salver-shaped flowers, deep purple; pusilla, one of the best, varying in colour from blue to lilac and white; pulla, having rich violet bell-shaped flowers; pusilloides, similar, but growing tall and with much larger flowers; and barbata, with large pale blue flowers, lined inside with long hairs.

There are several attractive forms of our native wood anemone that will flourish in shade, among which should be noted A. nemorosa Robinsoniana, with large sky blue flowers; A. n. Alleni, pale blue; A. bracteata, double white, fringed with green bracts; and, of course, the beautiful typical species itself. One of the daintiest of anemones is A. sylvestris, with large pure white flowers. The drooping buds are also attractive, and have earned this species the name of snowdrop anemone.

In a moist and moderately good soil, almost all the hardy primulas will revel, and most of the species may be grown in partial shade—in fact, *must* be accorded this position if they are to thrive freely. Many are difficult plants to grow—or, at any rate, die off after flowering, but there should be no difficulty with any of the following: Bulleyana, with whorls of handsome orange blossoms; Beesiana, similar, but with lilac flowers; denticulata, with large round heads of flowers varying in colour from purple to white, and one of the most arresting of the hardy species; cortusoides, like a dainty pink P. obconica; and pulverulenta, one of the easiest of all, with tall whorled spikes of rich crimson blossoms. Besides these, there are the polyanthus primroses, which will brighten up our rockery in early spring; while the choice double primroses are also worthy of a place.

Myosotis alpestris is a true perennial forget-me-not, and valuable for its bright blue blossoms; rupicola is a deep blue variety, its colour enhanced by a bright yellow eye; and Myosotis Ruth Fischer is another choice form, with very large pale blue flowers. Another plant that will introduce a touch of blue into the rockery is Omphalodes Luciliæ, with sky blue flowers and glaucous grey foliage. Blue is also a characteristic of members of the lungwort family (pulmonaria), though one hesitates to include these on account of their spreading habits. PP. angustifolia and azurea are two of the finest sorts, but both should be planted with caution.

Perhaps the most delightful of all rock plants are the saxifrages, many of which will thrive in shade. Chief of these sorts are the

THE BRIGHT BLUE FORGET-ME-NOT, MYOSOTIS ALPESTRIS IS A TRUE PERENNIAL.
It will succeed well in any rockery.

Digitized by Google

mossy saxifrages, with lightly cut emerald green foliage, and masses of white or pink flowers in May and June. Species that can be recommended are cæspitosa (white) and its many hybrids, including Clibranii, crimson; bathoniensis, brilliant red, almost scarlet; and Guildford Seedling, bright red. Other species of merit are: trifurcata, with graceful sprays of pure white flowers; Wallacei, large fragrant white flowers; and Rheii, of a pretty shade of pink. Among miscellaneous species, the popular London Pride must not be forgotten; while our native meadow saxifrage is very pleasing, especially the double form, S. granulata fl. pl.

B. D. SHAUL.

ATTRACTIVE PATH EDGINGS

THE ideal plant for a permanent edging to a herbaceous border is one which is not only attractive when in bloom, but neat and pleasing to the eye when the flowering season is over. Both these desirable qualifications are possessed by the old fringed white pink Dianthus plumarius fimbriatus, which, in addition, is to be reckoned among the most fragrant of all hardy plants. It is usually grown in a straight band along the edge of a border, but in Fig. 1 it is shown planted in clumps alternately with those of one of the mossy saxifrages, a rather original arrangement which has the advantage of securing a succession of bloom. Yellow or purple crocuses, by the way, may be planted under an edging of pinks and will look extremely pretty coming up through the grey-green foliage in spring, although their heavy masses of leaves in the dying-off stage are not very good for the pinks, perhaps. This objection scarcely applies, however, to the autumn-flowering Crocus speciosus, the big, violet blue, orange-anthered blossoms of which are most beautiful seen rising out of the cushions of either saxifrages or pinks. And the less tall varieties of Spanish iris—such as Bronze Queen (18ins.) and the bright yellow Belle Chinoise (20ins.)—may be planted under the pinks with a distinctly happy result. There is a pretty rose-coloured form of the fringed pink; a single white one; and the well known old pheasant's eye; all of which are suitable "edgers," as is the large-flowered Mrs. Sinkins. A typical edging of the latter is the subject of Fig. 2, the border to which it makes a charming finish being planted with blue flowers—lupins, delphiniums and Linum narbonense.

The colour of the common thrift is a rather muddy pink, but Armeria maritima rosea is a good shade of rose, and there is a new variety still deeper in tone, named—not very happily, it seems—Vindictive. The white thrift is ineffective by itself, but if planted alternately with the rose-coloured kind the two together make a very satisfactory edging. Of the perennial candytufts, Iberis sempervirens Little Gem is one of the best; but I. correæfolia Snowflake and I. c. Climax are equally desirable. These candytufts should be clipped back after flowering and occasionally renewed from cuttings taken from the most compact and floriferous plants. If grown from seed the height of the plants will vary and some will turn out shy bloomers.

AN ATTRACTIVE PATH EDGING WHICH REMAINS IN FLOWER OVER A LONG PERIOD.

It is planted with clumps of fringed white pinks alternating with tufts of mossy saxifrages.

Where space is not limited, nothing is more beautiful than an edging of Nepeta Mussini, with its clouds of soft purple flowers, especially if it has as a background a border filled with herbaceous phloxes in shades of pink and lavender. The fine display of catmint shown in the third illustration, however, edges two mixed borders which are divided by a paved path of sufficient width to allow the plant to be seen at its best. In some districts the nepeta is, unfortunately, not absolutely hardy, a proportion of the plants being apt to die off if the winter is severe; hence it is well to strike cuttings yearly as a reserve.

Many of the dwarf campanulas are most suitable for edging purposes, notably pusilla, garganica and Portenschlagiana. The white variety of the first is particularly pretty and dainty-looking. Viola cornuta is another free-flowering edging plant. Of this there are varieties ranging from light to deep purple and a pure white one which, in my garden, seeds itself freely and comes true, although, according to some authorities, this is not always the case. Tiarella cordifolia, the foam flower, is not very often seen as an edging, but for a slightly shaded and rather damp border it is as suitable as London pride and far prettier.

Veronica incana, with silvery leaves and violet flowers, is a sturdy little dwarf plant; but VV. repens, prostrata and rupestris require something in the way of rockery stones to ramble over; and the same may be said of the aubrietias.

Of edging plants whose merit depends on their foliage and not their flowers, some of the most satisfactory are Euonymus radicans argenteus Silver Gem and E. r. variegatus, the gold and silver thymes; the dwarf silvery-leaved groundsel, Senecio argenteus; Cerastium Biebersteinii; Stachys lanata, and Santolina chamæcyparissus. The latter shrub makes a neat edging if kept well trimmed, and can be easily struck from cuttings.

R. E. HEAD.

AN EDGING OF PINKS, EITHER THE WELL KNOWN MRS. SINKINS OR THE NEWER WHITE LADIES, GIVES A NEAT FINISH TO A BORDER.

ALONG A STONE OR GRASS PATH NOTHING IS MORE BEAUTIFUL THAN AN EDGING OF CATMINT.

THE BUSY MAN'S PAGE

The First Potting of Bulbs for Forcing.

THE first bulbs to be potted are those of Roman hyacinths and narcissus. These can be grown from the potting to the flowering stage without any fire heat. If a greenhouse is heated the flowering is hastened, of course, but fire heat is not absolutely necessary. The bulbs can be grown in a compost of leaf-soil two-thirds and loam one-third; or in loam and leaf-soil in equal proportions. If the compost is mixed several weeks prior to the date of its use, it will be improved in quality. Such composts should be mixed now, and the pots, preferably 5in., 6in. and 7in. ones, washed and dried in readiness for the potting of the bulbs directly they are received from the bulb merchants. The crowns of the Roman hyacinths must be left just clear of the surface of the soil in the pot, but narcissi bulbs may be covered with soil several inches deep. To obtain many blooms in a pot, several bulbs may be placed near the bottom and covered with soil, then more bulbs may be placed on them and also covered. All will flower at the same time. Directly the bulbs are potted, apply water, and, one hour afterwards, bury the pots under sand, ashes or common garden soil—sand for preference. In about five weeks time the bulbs will be ready for removal to a cold frame.

Schizanthus in Pots.

THE schizanthus is widely appreciated for flowering in the greenhouse in spring and summer; but the majority of amateurs appear to overlook the fact that it is equally effective in autumn. Plants from seed sown in July will be in full bloom in October and remain in beauty several weeks with the minimum of artificial heat. Sow in pans or pots of light soil, and ensure sturdy growth by allowing the seedlings plenty of light and air. From the seed-pans transfer to 3in. pots, and later into those 5ins. in diameter in which the plants will bloom. A compost of loam, leaf-mould and well rotted manure—the two latter constituting about one-half of the bulk—will grow fine specimens.

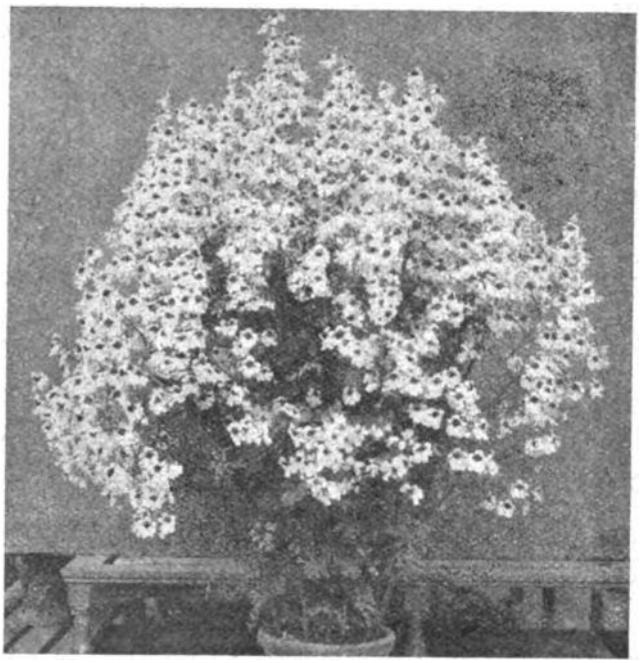
Watering Plants.

MANY amateurs seem to think that the first sunny day requires him to use the watering can in his garden—and the tragedy is that often in long droughts he becomes thoroughly tired in time and turns to golf or cricket. Now, the soil retains moisture for quite a long time. At a shallow depth it is cool and moist even after many rainless days, and the roots of plants find all they need there. Moreover, continual driblets chill the ground and, by preventing a full and natural aeration, tend to induce a certain sourness; again, they may defeat their own end, for plants, finding daily water so easily, fail to root moderately deep, and when the driblets are withheld they suffer at once. It would be better for the amateur to use his hoe much oftener—and it would be easier for him, too. Except in very light soils, the hoe tends to conserve the natural moisture of the soil, and in the light soils a surface mulch is easily superior to continual running with the can. Yet water must be given. First of all let it, if possible, stand in the sun all day, *i.e.*, avoid icy-cold tap water; then give large plants a good dose, hoe next night and let them go for a time. Seedlings, however, may require applications more often, but a light dewing overhead from the syringe often serves instead. Apply water in the morning or evening; hot sunshine and hot breezes, curiously enough, chill the ground after water is applied.

What to Do Before Going on Holiday.

MANY an amateur gardener feels some anxiety as to what will happen to his garden when he is away on holiday. Providing the vacation is not very prolonged, a good deal can be done to help the plants to take care of themselves, or, at any rate, to minimise the harm that a certain amount of neglect will bring about. One very good thing is to hoe the ground thoroughly before one's departure. This will not only destroy the weeds, but it will also help to prevent an undue evaporation of moisture from the soil. The next thing is to go the round of the borders and remove every flower that is open; in the case of sweet peas, and many annuals, it is rather wise to pick off any buds that are likely to expand within a week or so. Peas, runner beans, vegetable marrows and any crops of the kind should be gathered closely. In this connection it is really a good plan to get a friend to come in now and again, during one's absence, to gather all flowers or vegetables that seem ready for picking. This will make certain that production does not cease through seed setting and the maturing of crops. Some plants will stand particularly in need of moisture, such as vegetable marrows, runner beans, dahlias, tomato plants, etc. In these cases, hoe the soil well round the plant and then cover with a thick mulch or top-dressing of manure or even grass clippings, dead leaves and similar litter. This mulch should be well soaked with water just before leaving the garden, and it will prove of great assistance to the plants if there is a long dry spell. Mow the lawn closely and trim the edges the day before your departure, or the grass will present a very ragged appearance on your return.

Where there is a very considerable number of pot plants, it is desirable to make some arrangement whereby these can be watered. In the case of a few plants, which may be used about the house or in a small conservatory, it is best to arrange these in a cool shady spot out of doors, where the wind will not damage them. Stand on a layer of cinders or on boards, to prevent worms working up through the holes in the pots. Loosen the surface soil with a hand-fork and then cover with a thick layer of fibre, moss, or anything similar. Press the material well down and soak through and through with water. In the case of ferns, it is rather a good plan to stand the pots in saucers of water as well. Treated in this way, pot plants will not suffer to any great extent for a week or two, and should there happen to be a few showers of rain no harm will come to them at all.



A WELL GROWN PLANT OF SCHIZANTHUS GROWN FROM SEED SOWN IN EARLY AUGUST.

The butterfly flowers are most useful for greenhouse decoration during winter and early spring.

How to Sow Seed of Herbaceous Calceolarias.

THE pouch-like flowers of these plants are exquisitely marked, and are borne in great numbers on well-grown specimens. The flowering period is the spring of the year; and seed sowing is done during the middle of the summer. The plants thrive best in cool quarters, so that at this season of the year special care must be taken, not only with the seeds, but also with the seedlings, or the latter may be lost. A consistent state of moisture, both in the atmosphere and in the soil, is essential to success. Pots or pans should be used, not boxes, and both the pan and the crocks used, to ensure adequate drainage, should be clean and dry. Equal parts of loam and leaf-soil should form the compost, with just sufficient coarse sand to make it porous. Manures are not necessary. On the crocks place a few half-rotted leaves or some fibrous turf to prevent the soil falling among the crocks and clogging the drainage. Three-parts fill the pan with the compost and make it level and moderately firm by pressing with a piece of board or the bottom of an empty pot. Apply water through a fine rosed watering can and, one hour afterwards, sow the seeds very thinly on the moist surface. Do not cover the seeds with sand or soil, but place a square of glass on the pan and cover the glass with moss or brown paper. Then there is the question of position for the pan. There is not any better than in a frame fixed on the north side of a wall. If the pan must be kept in a greenhouse, then provide special shade for it and a bed of damp ashes as a base. Directly the seedlings can be seen, remove some of the covering material; do it by degrees and also, at the same time, raise the glass a little. On no account must the seedlings be exposed to direct sunshine—plenty of light, but not sunshine. If the glass was left on and the sun shone on it, the heat would be so great in the small space that the tiny seedlings would be scalded wholesale. Cool, airy conditions throughout are essential. Once the seedlings have made their second pair of true leaves they can be pricked off.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

The Best Town Flower.

Hints on Layering Carnations.

IT is safe to say that no hardy flower—except, perhaps the rose—is so popular as the carnation. The reasons for this are not far to seek. Its perfect hardiness is beyond question, and the "bloom," or grey colouring matter on the leaves, which is really a thin layer of wax, enables it to withstand the fog and dirty atmosphere of towns. Although carnations can be raised from seeds, the best varieties are perpetuated by layering. An old plant will continue to flower for two or more years, but the best blooms are obtained from young plants, and a few should be raised each year for renewal purposes. The following is the method to adopt: First prepare the soil round the plants, by adding light soil to a depth of 2ins. Decayed turves are the best for this, but in any case the soil must be friable, and sandy if possible. The other preparations necessary are the provision of a sharp knife, and a number of wooden pegs such as can be cut from hazel twigs.

How to Layer.—There are two kinds of shoots to the plants—those with flowering stems, and side shoots which will not flower until next year. The latter are the ones to be layered. Carefully remove from the base of the shoot selected two pairs of leaves. Now make a cut in the stem, slanting upwards from just below the lowest joint from which the leaves have been removed. The stems should be nearly severed, the cut being nearly 2ins. long, and seven-eighths of the way through the stem. Peg the layer down into the soil so that the cut is open and covered to a depth of about 2ins. In about three or four weeks roots will form from the open cut, and a new plant will have been formed. Generally, about six new plants can be made in this way from each old one. When the layers have become well rooted, sever them from the parent plant by cutting with a sharp knife through the stem near the old plant. Leave them undisturbed a few weeks longer, to make sure they are well established, when they can be removed as desired.

Lime the Soil.—The wild carnation grows on old walls and in limestone regions. This fact should not be lost sight of in preparing the soil. Lime, and especially old plaster rubble, should be mixed liberally with the soil when dug. Bone-meal is a safe fertiliser.

In Boxes or Pots.—If it is desired to increase plants in boxes, the process is similar to that in the open border, except that frequent soakings of water will have to be given. In pots, the plants are layered by sinking the pot in a box of soil or a frame, if one is available.

Among the Summer Flowers.

The Importance of Thinning Out.

IN my garden the vegetation grows too quickly. Seedlings and weeds, left alone for a week, race each other to fill the all-too-narrow borders. But this quick growth of weed and flower is healthy. Beginning at one end of the border, I shall pull out the weeds and ruthlessly thin out each group of seedlings. Clarkia, sweet sultans, sweet alyssum, and such annuals, will be left 6ins. or more apart. Those who watch will call me callous and hard-hearted, but I smile and work steadily through the throng.

Thin Perennials, Too!—Michaelmas daisies, heleniums and other perennials also receive a thinning. From each root I remove thin growths, leaving only about six of the strongest shoots to each. This makes fine blooms in autumn. And how much more beautiful is a solitary stem of Michaelmas daisy than a crowded mass!

Hoe! Hoe! Hoe!—This is the constant cry of this season. After the weeds are slain, and the plants in my border thinned out, I sprinkle a little soot and a pinch of fertiliser round each plant. This I hoe in, using a small hand fork where the plants are too close to allow the use of the hoe. After which it needs but a sunny day and a night of rain, and the border is a sight fit for the gods!

A Use for Waste.—Do you burn an acetylene lamp on your cycle or in the house. Then empty the spent calcium carbide into a box in an out-of-the-way corner of the garden. It is largely composed of lime, and can be used instead of this substance; but before use it should be allowed to weather for a time.

A Popular Greenhouse Perennial.

HYBRID strains of streptocarpus make a fine show in an amateur's greenhouse. The best flowers are obtained by treating the plant as a biennial. Seeds can be sown now for next season's flowers. They can be grown in a cool house in summer, but frost must be kept out in winter. While the flowers are in bloom, the atmosphere should be kept dry.

All the modern hybrids are the result of crossing several wild species, notably Dunni with one huge leaf, and brick red trusses of flowers; S. Rexi, with bluish flowers; and parviflorus, with white flowers. Later on the progeny was crossed with other species, like S. Wendlandi, clear blue. All are natives of Africa. The flowers are bell-shaped and vary from pure white to crimson, mauve, rose, cerise, purple and other shades. There are no yellows. Special kinds can be propagated from leaf-cuttings. These plants revel in sandy loam and leaf-soil. Plenty of air is needed at all times, and the winter temperature should be somewhere between 40° and 50° Fahr. If they are given these conditions they grow readily.

THE STREPTOCARPUS IS A FIRST-RATE PLANT TO GROW IN A SMALL GREENHOUSE. *Seeds can be sown now.*

How to Succeed with Rockfoils.

LONDON PRIDE, the commonest of the saxifrages, or rockfoils, is known to everybody; but there are many others (over 300 species) known to us. Saxifrages are readily increased by division or from seed. Ordinary soil is suitable for their cultivation, but in the case of those with silvery encrusted markings a limestone soil, or one containing lime in some form, is necessary. For convenience, saxifrages are grouped according to their habit of growth. Saxifraga Burseriana and S. apiculata are two examples of the fascinating cushion saxifrages. Some of the members of this group are difficult to cultivate. As a rule, they like an open sunny position, in well drained, light, gritty loam with plenty of lime.

Mossy Saxifrages.—This group of saxifrages has dense tufts of moss-like foliage. They are very effective used as edgings, especially alongside stone-paved walks. The variety muscoides will form drifts of red flowers, which are most attractive. Then there are the silver or encrusted saxifrages. Their rosettes of stiff leaves lie close to the earth, and from their centres rise the loveliest spikes of flowers. Aizoon and longifolia are two of the best of this group.

Creeping Rockfoils.—Many of the saxifrages have a creeping habit, very useful in clothing the rock garden. Oppositifolia is a variety with rosy crimson flowers, and there is also a white form of this plant.

When once planted, saxifrages need very little attention. Weeds need to be pulled out as soon as they appear. This is of special importance in the case of the mossy saxifrages, among which grass will sometimes appear and grow so rapidly that it will smother the plant. Smoke is an enemy to the saxifrages, particularly those of the silver type. But London Pride and several of the mossy saxifrages will grow almost anywhere.

Digitized by Google

NOTES ON THE FLOWER GARDEN

What to Do in the Flower Beds and Borders Next Month.

TO keep the flower beds neat and trim an effort should be made to go over them regularly with hoe or spud, etc. Water where necessary or mulch to prevent those flowers requiring moisture becoming too dry if the weather is so inclined. Remove faded leaves, flowers and weeds. Pinch off any excess of shoots anywhere to preserve the outline of bed or border. There is certainly a certain amount of beauty in a straggliness here and there. Severe and formal lines are too cold to appeal to the artistic eye or the real lover of flowers. But some slight effort at the maintenance of orderliness must at all events be made, especially in regard to carpet bedding.

Give such plants as echeverias and sedums a little liquid manure (well diluted if the soil is dry). It will improve them. If sedums look irregular, they may be pressed down in the centre with finger and thumb. This is best done very slightly and repeated if necessary.

Dahlias will also require a little weak manure liquid. Tie the shoots to stakes as they grow. A wire trellis is suitable for dahlias grown in rows. For exhibition the plants must not be allowed to bear many shoots or blooms. A judicious thinning is the way to score with fine blooms.

Roses and any other plants subject to mildew will need repeated dustings with sulphur. Fasten climbing roses to supports. Thin out weak shoots from roses, shorten strong-growing shoots so that there may be no undue flow of sap to the formation of wood. Stake and tie chrysanthemums and gladioli, etc. Lift double-flowering herbaceous plants, divide and plant again when past flowering.—J. W.

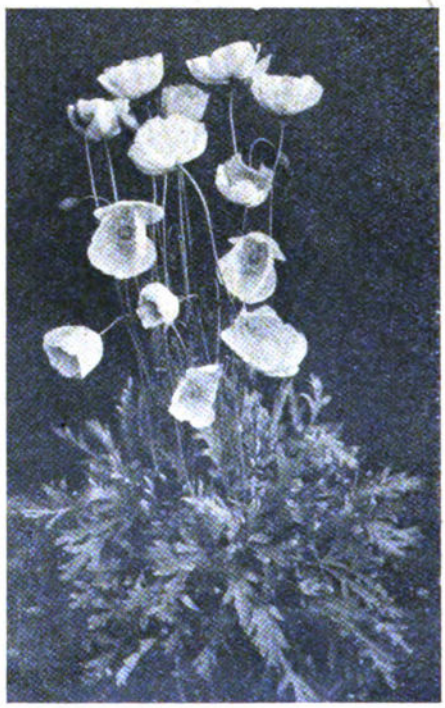
How to Cure Damping-Off Among Seedlings.

A HEAVY toll of mortality among seedlings is claimed every year by the disease commonly known as "damping off." The fungoid disease attacks the young seedlings just above or just below the ground level, causing them to collapse and die, owing to the destruction of the stem tissue. The fungus enters the plant through the root-hairs. Once having gained admission, it spreads with great rapidity through the soft tissues, causing the death of the plant cells.

Control Measures.—The chief line of treatment is the sterilisation of the soil. This is effected by different methods: by steaming, baking or chemical treatment. All pots or boxes used for seed-sowing should be scrupulously clean and, if necessary, treated with a two per cent. solution of formalin. Water tanks should be emptied, scrubbed with a strong fungicide, and refilled with fresh water. As a means of prevention, thin sowing of seed should be the rule. Conditions favourable to the disease are: (1) lack of sunlight; (2) an abundance of moisture; (3) lack of ventilation. Therefore, it behoves the gardener to be extremely careful with the use of the water-pot, and admit plenty of air on all suitable occasions. Plants which have contracted the disease should be thoroughly dusted with fine flowers of sulphur. Affected plants should be removed from the seed-pans or boxes with great care. For the efficient control of this disease a compound, known as the "Cheshunt Compound," has been used with great success. The recipe for making is as follows: 10 parts by weight of ammonia carbonate, 2 parts by weight of copper sulphate. The ingredients should be ground very fine separately, and then thoroughly mixed together. Store in a dry place. For applying, use 1 oz. to 2 gallons of water. The soil may be watered with this solution before the seed is sown, or after sowing. Apply another application once before "pricking off" and once when potted into "sixties." If this method is adopted, very satisfactory results will be obtained. An old remedy which is often used is permanganate of potash; this is, to some extent, useful, as the potash confers a certain degree of immunity; it also acts as a tonic on the plants, thus assisting them to resist the fungus.—J. E.

Iceland Poppies for Next Year.

THOSE who desire to raise a stock of Iceland poppies from seed, should not omit to sow during the next few weeks in order that the young plants may be got into nursery beds or a cold frame for the winter. As the seeds are so small, it is much better to sow them in boxes, rather than in the open ground, and to this end boxes of light soil should be prepared, the top surface being made fine by passing through a sieve. Thin sowing is essential, and if, afterwards, they are watered in with a fine-rosed pot, no covering of soil will be needed, a sheet of brown paper answering as a covering until germination takes place. Young plants are best pricked off into pans or boxes until large enough to go out of doors, when they should be found a place under the shelter of a wall or fence if possible. If this cannot be done, it is best in a time of frost to intersperse among them a little straw or hay. This applies more particularly to first year plants, as established clumps are hard enough to do without such protection. Iceland poppies may give little or no signs of life much before February or March, but they soon make progress as spring approaches. For the first winter it pays to be extra careful with young plants, by affording them protection. The flowers of the Icelands are most useful for cutting, and the modern sorts as represented by the Sunbeam strains, are even more so. To anyone thinking of sowing seed I commend the latter. Of one point about gathering flowers of these poppies which is not always considered—and that is the need to cut the stalks, as, if one attempts to pull them, in most cases, roots are disturbed, if a section of the plant is not uprooted.—F. W.



ICELAND POPPIES ARE VALUABLE FOR BOTH GARDEN AND HOUSE DECORATION.

Plant Freesias Now.

THERE is a mistaken notion, held by some amateurs, that to grow freesias one must be able to give them heat above the normal to be found in most greenhouses, and that it is useless to attempt their culture otherwise. A further mistake sometimes made is to think about them only when ordering the spring-flowering bulbs in November. Freesias require long growth, and should be planted either during July or August. Planted later, weak puny growth results, and they are never satisfactory. They are most effective when planted in pans, fifteen or so bulbs to a pan, or six or seven bulbs in a 5in. pot. A compost made up of sandy loam, a little leaf-mould and decayed manure will suit them. Special attention should be given to drainage. They can either be kept in a cool part of the greenhouse or in a cold frame for a few weeks, but on the approach of frost must be removed indoors. One may, if so desired, introduce them to the warmth to be found in the striking-pit—say 65° Fahr., and so have early flowers in spring; but, grown under temperate conditions, blooms will follow not long afterwards. Freesias are so valuable, on account of their exquisite perfume, that, having regard to their not very great expense, one may have flowers for succession over a longer period by keeping them in a frame, free from frost, and introducing them to heat as occasion requires. They benefit when in full growth by plenty of moisture, and liquid manure given once a week in a diluted form will help them. Bulbs increase rapidly—so much so, indeed, that to an amateur the question of raising from seed is hardly worth while, as a couple of years must elapse before the young bulbs bloom.—CLAREMONT.

Double Daisies for Edgings.

Divide the Plants Now.

AMONG our oldest garden flowers are the double-flowered daisies, which, though not very frequently found in the garden of the present-day amateur, are admitted to be both decorative and useful. When used nowadays it is mostly as a carpet for some early summer border, but they make efficient and attractive edgings, or they can prove of great use in a mixed bedding design. In order to retain these daisies at their best they must be treated like the polyanthuses and divided up annually, or, at least, every second year in summer; planted again after division, they take readily to their new quarters, but many people prefer to grow them on temporarily in a shaded, moist bed, where they quickly attain to large size. Giant doubles, almost as large as asters, are readily raised from seed sown about this time; these are very fine in beds, but the best plan is to raise fresh stock every year. Sow the seed thinly and transplant the seedlings into a moist, cool bed at earliest; bed them out in late autumn or next spring. Giant singles in pink and white can also be raised from seed; the flowers are really semi-double and very graceful, preferred by some growers to the other kinds. In doubles one may have, from seed, whites, reds of various shades, and a fiery scarlet called Firefly. The old named doubles are still to be had from certain nurseries; though I have lost one or two kinds in the rush of work, I used to grow Dresden China, Rob Roy, Victoria, Eliza, Alice, Hebe—all

Digitized by Google

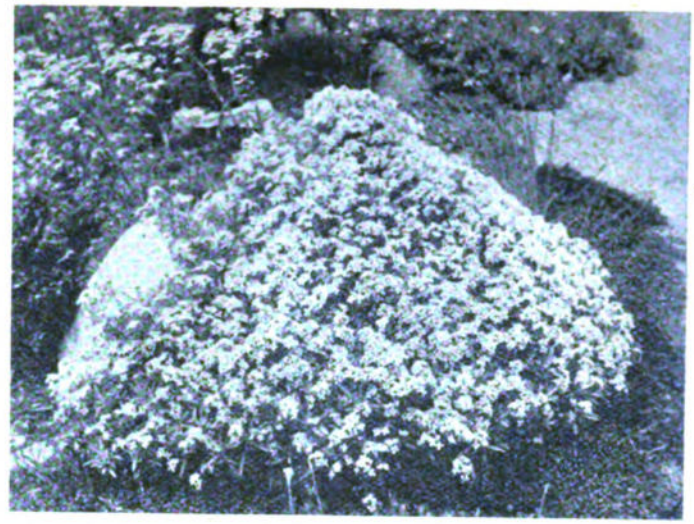
in different shades of red. In whites, I had Venus, The Bride and Albino. One of my losses is the hen-and-chickens variety, which produced round the flower as it faded a number of miniature daisies similar to the centre flower.—HUGH AITKEN.

Worry with Sweet Peas.

SWEET PEAS are but seldom infested with insects, but should any appear in destructive numbers, then the grower must at once spray with some good proprietary insecticide and repeat the application five days later. Fungus diseases are, however, much more prevalent. and beginners must understand that, if they are to be cured at all, it is a fungicide like Bordeaux mixture, liver of sulphur, lime sulphur or a proprietary compound which is required. Streak disease, which seems less prevalent than it used to be, cannot at present be cured. Root out a plant infested badly, burn it, and syringe plants and soil with permanganate of potash, a quarter ounce in a large pail (2 gallons or more) of water. Root rot and collar rot also cannot be cured, for when the plants begin to collapse they are beyond recovery. Carefully root them out and lime the spot well. Mildew and mould are apt to come when climatic conditions bring muggy, damp weather. Nothing much can be done, but I always like to spray with liver of sulphur, 1 oz. in 3 gallons, and to apply alongside a little fertiliser to stimulate growth. Preliminary sterilisation of the soil is essential when any disease is suspected to be lying dormant in the garden, but even then the fungus may blow in from nearby clover fields.—H. A.

An Attractive Dwarf Evergreen.

THERE is no more attractive little evergreen among the ledums and their nearer allies than the sand myrtle, Leiophyllum buxifolium. For a cool spot in the rock garden, the front of the mixed border, or associating with dwarf heaths, this is an ideal shrublet, its compact habit, small and glossy dark green leaves and amenable disposition never failing to win admiration at any season. But that is not all, for L. buxifolium is a flowering subject of distinctive merit. In early spring it becomes studded with clusters of pretty rosy crimson buds, and when these, breaking into crystal stars, are fully expanded, the whole plant becomes a mass of scintillating white blossom which lasts for several weeks. Though usually classed as a peat plant, L. buxifolium will do well in any lime-free loam, often in a quite sandy root-run, and it is one of those subjects which will carry on " for many years with unfailing satisfaction. Propagation may be effected by layering some of the outer branches in a bed of sand and leaf-mould, or by cuttings about 1½ins. long struck in pots of sandy peat in August. But it is often possible to detach rooted portions from an established plant, and these, of course, will come away more quickly. A full-grown specimen does not usually exceed 8ins., and there is a prostrate form of only about half that stature.—N. WALES.



A NEAT ROUNDED HUMMOCK OF ALYSSUM SPINOSUM.
A useful rock plant.

Erigerons from Seed.

ALTHOUGH growers generally sow perennials in May, or even earlier, I find that the erigerons succeed quite well from sowings made at this time in a moist, semi-shaded bed. Thinned out and transplanted when they are quite small, they grow rapidly, and by late autumn make excellent plants, which may then be put into permanent sites. There being nothing quite like them in mid-summer, the erigerons may be raised from seed on a more wholesale plan and used in suitably arranged summer beds; indeed, I have frequently had them in this fashion and found them highly satisfactory. Speciosus, also known as the summer or mountain daisy, is the most common variety grown in borders. The flowers are a distinct, clear, but pale mauve with yellow centres of the daisy type. Coulteri is a white, the earliest of the genus, a plant in great demand in summer for cut bloom. Aurantiacus hybrids include various shades, white, pink and yellow predominating; these are dwarfer than the others, but very fine and showy border plants. Some varieties of alpinus and other species less frequently met with also succeed quite well from seed sown as late as this. I recommend readers, in addition, to save seed of fine named varieties which they may have, this seed to be sown next summer. Most varieties set seed freely. Note that slugs and snails are very destructive to seedling erigeron, and great care must be taken lest the pests ruin good work.—LANARKSHIRE.

AN ATTRACTIVE EVERGREEN SHRUB FOR THE BORDER OR ROCKERY, LEIOPHYLLUM BUXIFOLIUM.

A Useful Rock Plant.

UNDER the name of Ptilotrichum spinosum stands that sub-shrubby crucifer known to catalogues as Alyssum spinosum. A more useful plant of its sort for any really hot, dry spot where the soil is poor I do not know, for it is as drought-proof as a cactus and of no small merit both in foliage and flower. Pt. spinosum forms a neatly rounded bush rather under a foot in height, its mass of spiny, tortuous branches and silver-grey foliage clinging together in a springy hummock which is always neat and attractive. In early spring the little white flowers appear in great profusion, sheeting the plant with white, and these will often prevail until summer is far advanced. In addition to the type plant there is a variety, Pt. s. roseum, whose blossoms are faintly tinted with lilac, this giving the mass a rosy flush. For the rock garden where silver-leaved subjects are desired, Pt. spinosum is indispensable. It is quite hardy and easy in a stony, dry soil, and by no means difficult to increase by short summer cuttings struck in pots of sandy soil in a cold frame.—A. T. J.

A Free-Flowering Bramble.

FOR several weeks past large specimens of Rubus deliciosus have been quite a feature in many gardens, carrying a host of large snow white flowers fully 2ins. across. It is a native of the Rocky Mountains and is known as the Rocky Mountain bramble, and it is a plant well worthy of attention, not only for the shrubbery, but also as isolated examples in close proximity to the rock garden, while as a wall plant, where it is not too confined, it will be a decided success. It thrives best in a sunny position and is not particular in regard to soil, although the best results are obtained in a loamy root run.

The leaves are somewhat similar to those of the black currant and it can be increased by cuttings similar to that fruit, but the percentage of failures will be greater, in fact, a few only will probably form roots. Layering is another method of propagation. After flowering a large number of new growths will appear, and now is a good time to carry out any pruning. This consists of cutting out some of the old wood to prevent congestion, and as a rule the branches or shoots should be cut back to new growth. No set system of pruning is advocated. Much will depend on the space allotted to the plant, its position and general health. Nevertheless, remove as much old flowered growth as possible, and encourage the current season's shoots, which will be a mass of bloom from June onwards.

R. deliciosus is one of the best flowering shrubs, the blooms resembling a single white rose. Moreover, it is hardy and can be recommended as a garden shrub of real merit. There are two forms in cultivation, and the best one ought always to be chosen.—W. B.

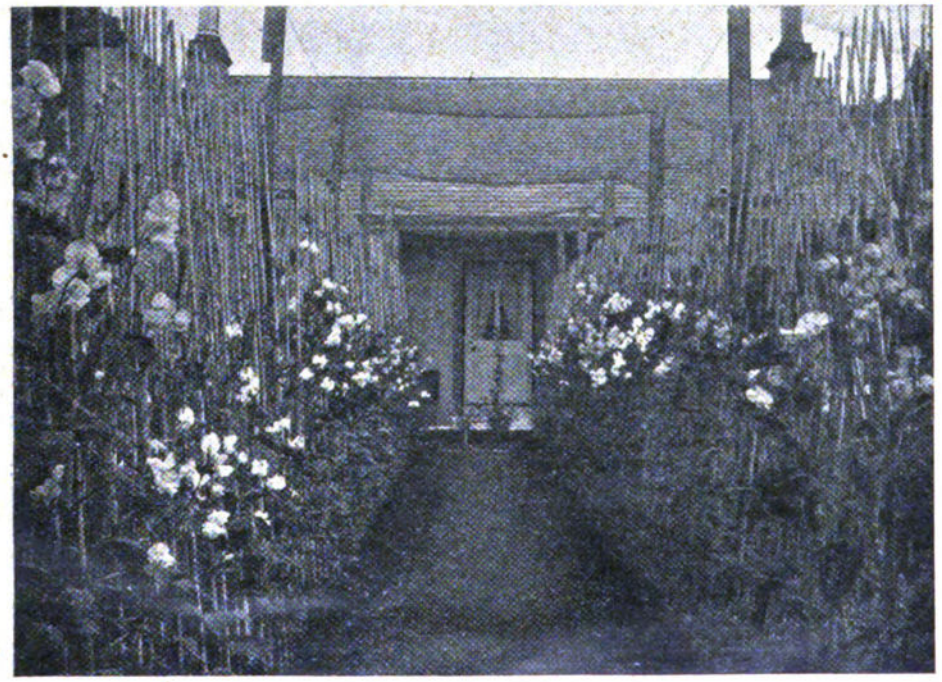
FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

"LEAVES have their time to fall and flowers to wither," but weeds belong to every season, and in the average garden they are a source of perpetual trouble, causing an expenditure of time and labour that can be ill spared in the busy season. This unsatisfactory state of things is in large measure due to the supply of farmyard or stable manure that is dug into the soil annually, for it is a common experience that as that commodity becomes scarcer its quality and value as a fertiliser depreciates. With the object of increasing the available supply, the modern manure heap has become the dumping ground for every kind of refuse, and the strange and undefinable mixtures frequently sold under the generic name of manure accounts for many of the new weeds that make their appearance in the soil. Not so long ago I laid in a stock of so-called manure in the autumn at a cost of 12s. 6d. per cart, and when the time came to incorporate it with the soil the surprising discovery was made that it was largely composed of apples and oranges in an advanced state of decay. When the attention of the purveyor was called to the fact that he had been paid for manure and not for rotten fruit, he replied quite seriously that apples and oranges were the best things that could be put in the ground. Of a truth, we gardeners are always learning, and in the search for knowledge I found out a beautiful villa garden where excellent results were obtained without the aid of organic manure. The herbaceous borders, rose beds, fruit and vegetable quarters were conspicuously clean, and the various subjects were strong and healthy as the result of the owner's personal attention and treatment. Herein lay the secret of success. All the grass cuttings and lawn mowings were utilised as plant food. Throughout the summer the grass was carefully collected and, after being mixed with soil and sulphate of ammonia to promote decay and destroy insect life, it was stored in a heap and, as the successive weekly cuttings were added the dimensions of the mound were materially increased by the end of the season. When spring comes round the accumulations of the previous summer are dug into the soil and are also used as a compost for pot plants. A small quantity of last year's stock, which was reserved for begonias, was in such a fine condition that it passed freely between the fingers. Such a cheap and easy method of providing a clean and natural plant food is within the scope of every gardener.

The presence of so many "rogues" in the Scottish Sweet Pea trials is a testimony to the sportive character of the popular annual, and emphasises the difficulties which beset raisers in their endeavour to produce varieties that are true to type. It is beyond question that certain sorts have defied all attempts made to fix them. I can recall a beautiful variety named Audrey Crier, a bright rosy pink form of Countess Spencer with slight flush of salmon on the standard, which was first exhibited in 1905. In the following year it received a first-class certificate and the silver medal of the National Sweet Pea Society awarded to the best variety of that year; but in the trials at Reading it was found to be so sportive that the raiser was asked not to put it on the market until it was more fixed. In later years Messrs. Dobbie and Co. offered a strain which gave a high percentage of flowers true to type, but Audrey Crier was never properly fixed. To that somewhat ancient example may be added a modern illustration. At the recent Chelsea Show the Edinburgh firm staged a meritorious white sweet pea which throws an equally good cream form in the proportion of approximately three white to one cream. Specimens of each were exhibited side by side, and Mr. David Cuthbertson assured me that all attempts to fix it had failed. Twenty years ago one of our leading raisers of sweet peas was Miss Hemus of Upton-on-Severn, who produced Paradise, Evelyn Hemus and other desirable varieties. Some sorts, however, did not come true, and complaint was made that she was in too great a hurry in distributing her new varieties. Although a considerable improvement has been effected since that time, the results of the Scottish trials show that raisers encounter similar difficulties to-day. No better proof of this need be quoted than the appearance of a rogue in Boy Blue.



SWEET PEAS GROWN FOR EXHIBITION PURPOSES AT THE SCOTTISH SWEET PEA TRIALS.

My attention has been called to the colour variation in the flowers of catmint (Nepeta Mussini), an old hardy perennial that has advanced rapidly in public favour within the past two or three years. Some shades suggest deep purple and others deep blue, whereas the true colour is pale purple or blue that has the appearance of lavender when seen at a distance. According to Nicholson's *Dictionary of Gardening*, the flowers of N. Mussini are pale blue spotted with white towards the throat, while the anthers are purple. Other authorities describe the colour as lavender blue; while a lady writer says it is "Smothered from spring to autumn with a cloud of misty blue-mauve flowers." Because of the natural straggling or spreading habit of the plant, it must be given plenty of room, and when used as an edging it may be necessary to shear and trim it in order to keep it within bounds. It has been introduced in the floral schemes of railway stations, and the effect is very pretty, especially when used to decorate fireclay vases and hanging baskets.

Mildew, which is an annual menace to certain varieties of roses, has already made its appearance in several gardens located in the West of Scotland. This virulent parasite is in its primary stage when the greyish-white mould appears on the upper and under sides of the foliage, causing the leaf to curl or shrivel, and as the weather is a contributory cause of infection, growers need not be surprised if the disease becomes epidemic in August and September. On the principle that prevention is better than cure, a systematic course of syringing should be initiated at once, and having regard to predisposition endeavour to keep your plants in good heart. Until recently there was no known remedy for mildew, but "Kuremil" is guaranteed by Messrs. McGredy to be a cure and a preventive. This preparation is sold in the form of a powder, and a 2s. 6d. packet is sufficient for 32 gallons. Then there is a simpler and more economical remedy which the *American Rose Annual* says "has been most effective" in the United States. The formula for this is to dissolve 1 oz. to 1½ oz. of common baking soda (bicarbonate of soda) in 1 gallon of boiling water, which, of course, is afterwards cooled before use. With the object of causing the spray to adhere to the foliage, 7½ oz. of whale oil or fish oil is added to 5 gallons of the mixture; but ¼lb. of soft soap will serve the purpose as well. The late Rev. J. H. Pemberton found that 1½lb. of Calvert's carbolic soft soap melted in a 2-gallon pail of water was efficacious as a spray. This preparation entails no danger from an overdose, and the foliage is cleansed and stimulated thereby. A 3 per cent. or 4 per cent. solution of the best quality soft soap is also recommended by the National Rose Society; and dusting with flowers of sulphur every ten days is said to be sufficient to control the disease. Try one or other of these prescriptions, and begin the treatment at the earliest opportunity.

NEW SWEET PEAS.

Novelties at the Scottish Trials.

SWEET pea enthusiasts north of the Border made their annual pilgrimage to Helensburgh on Saturday, July 9th, for the purpose of inspecting and passing judgment on the eighty-nine new varieties not in commerce which are under trial by the Scottish National Sweet Pea, Rose and Carnation Society. Mr. John Smellie, the energetic secretary

Digitized by Google

of the Society, is responsible for the cultivation of the plants, and his work is somewhat handicapped at the very beginning by the late delivery of the seeds. These were not sown until the middle of October, which is about three weeks behind the time for autumn sowing in the west of Scotland, especially when germination is obtained without the aid of artificial heat. The seedlings were planted out in the first week of March, and in view of a recent note on the subject it may interest readers to learn that the peas were transferred from the pots without disturbing the roots. In his long experience Mr. Smellie has tried both ways, and unless where the plants have been established for a long period in the pots and there is a mass of roots in ball formation he favours that system.

As was to be expected, the peas were not in the forward state of growth experienced in the two previous years. For this the weather was entirely responsible; but as the plants, which are cultivated on the single stem principle, were in a robust and healthy condition, that defect will disappear as the season progresses. Generally speaking, the standard of quality also compared unfavourably with that of the 1925–26 trials. Two and three bloom stems were the rule. Judged on the condition of the flowers on our visit, it must be admitted there was not an outstanding sweet pea in the whole trials. Even Mrs. Searles, the beautiful cerise introduction and one of the successes of last year's trials, was disappointing; while Sunkist, the cream-ground Youth so much admired at the Chelsea Show, revealed the colour defect that seems to be inherent in the picotee edge class. In their later inspections the judges will doubtless discover a number of meritorious examples; but a larger proportion than usual are already out of the running because they are not true to colour. Rogues seemed to be on the ascendant, and two or three varieties were so badly mixed that the type was in a minority.

The first two rows were occupied by pink-coloured peas of which there were twenty-six varieties, representing nearly one-third of the total entries. When the too-much-alike varieties and the unfixed are eliminated, there will probably remain half a dozen in the final test. Among those that passed muster on our visit were two cream pinks, showing double standards, a strong-growing deep pink with bold, well formed blooms; and Pinkie, which bears a close resemblance to Hebe.

If the truth be told, the white class must be written down a failure, for there was not one of the seven lots which could pass the elementary test of fixity and purity.

Lavenders and purples suffered badly in comparison with the grand specimens in the 1926 trials.

The cerise varieties, ten in number, suggested the condition of the curate's egg, being good in parts. No. 8 was one of the few sorts showing four flowers on a stem, and the large blooms were well placed. It also had the merit of coming true. Mrs. Searles is a lovely bit of colour and, while the stems only carried two or three blooms, the size of the individual flowers testified to the capabilities of Mr. Bolton's grand pea. A cerise scarlet and an orange scarlet also gave promise of better things in future.

The rose shades contained one good specimen; and the honours in the blue section were shared by No. 86, a fixed medium shade, and No. 61, a big bold pea of an intense deep colour. Among the other classes was a strong-growing crimson and a big frilly pea in the fancy class, both of which attracted attention; but to our mind the most distinctive-coloured pea in the trials was No. 41. It is described as lilac by the raiser, but that term does not do justice to the colour. Some of the standards are double in form, while the colour is of a deeper shade than that of the wings, producing a pleasing effect which is emphasised when arranged in a vase.

ST. MUNGO.

WHAT OUR READERS SAY

BUDDLEIA ALTERNIFOLIA.

SIR,—I am much surprised to find an idea existing that Buddleia alternifolia only bloomed on the old wood, and in consequence many of these shrubs lose their refined habit of growth through a lack of pruning.

Every spring I cut this shrub back to strong buds or shoots as near as possible to the crown. It thus retains its dwarf and graceful habit and never fails to bloom profusely, rendering it very desirable for the rock garden.—P. E. E. C., *Cornwall*.

A LOW DRY WALL FOR A SLOPING LAWN.

SIR,—A dry wall substituted for a sloping lawn and border often greatly improves a garden. The first picture shows the sloping lawn and border before alteration. In the second one, the lawn has been sunk to a depth of 2ft., thus levelling it out and permitting the introduction of the stone steps which add dignity to the garden. The dry wall planted with suitable creeping plants provides beauty and interest.—H. RUSSELL THOMPSON, *Gloucestershire*.

GERANIUMS WITH PRETTY FOLIAGE.

SIR,—As a constant reader of your valuable paper for some years past, I read with interest the article by "W. F." on "Geraniums with Pretty Foliage" (page 420), and I fully endorse his remarks and put in an earnest plea that these old favourites may once again come into fashion, if not for our flower beds, at least for the greenhouse staging, for summer and winter decoration. The varieties he mentions may be old, but with the exception of Flower of Spring and Mme. Pollock, the others are quite new to me in this part, but he has omitted to mention the very best tricolour of all, Mrs. Henry Cox, which I only see is listed in J. W. Cole's list, at Peterborough. I have a batch of these adorning the centre stage of my tomato house and the sight is most effective. I keep this centre stage for geraniums only, and the soft blooms of pink Victory tone well with a good broad edging of Mrs. Henry Cox, and make a most pleasing sight.—C. W. HAMMOND, *Glos.*

HELIOTROPES IN TUBS.

SIR,—The method of growing heliotropes in tubs by H. Allan is very interesting and will, no doubt, be widely read. But as we all have different ways it may also be interesting to give the method by which I have been able to form a full tub of heliotrope in one year. That method may be useful to those who are anxious for quick returns, and who have not the convenience for wintering large tubs. Unlike Miss Allan's method, however, it involves the growing of several plants to fill the tub. Usually when I have the opportunity I make a practice of growing the heliotrope as a standard, and always have fresh plants each year. To form a standard in one year means that there must be a long season of growth, and to ensure this I take the cuttings during the last week in July. The cuttings are rooted in sand in the greenhouse and when rooted planted in a box. When they have made nice plants they are potted into 3in. pots. From this size they are in due course transferred to 5in. pots, and after the turn of the year to 7in. pots, which is quite large enough to plant from. I have tried moving them to larger pots before planting them out early in June, but it has not been successful. During growth the plant is kept to a single stem till it reaches a height of 4ft.

HOW TO TREAT A SLOPING LAWN TO MAKE IT EFFECTIVE.

A low retaining wall may be built and planted up with suitable rock plants to provide beauty and colour.

Digitized by Google

when the top is nipped out and the three or four upper side growths allowed to develop, these in due course being also stopped, usually when they are about 6ins. in length, but all these growths are stopped at one time. In the spring side growths from the lower part of the stem are allowed to grow to such a length as to give cuttings for making dwarf plants. Now we come to the formation of the make-up of the tub, which may be done in May. Three of the tallest of the standard plants are chosen and set centrally in the tub of soil. Then shorter standard plants, which have been pinched at a foot lower than the tall ones, are planted, also in the tub round the others, and some more well grown dwarf plants are planted for the bottom. These plants are all staked, and as they grow the growths are tied so as to make a good outline so that when they are well grown they look like one huge plant. Of course, the tub might be kept for another year, if desired, but for the purpose of standards, I always prefer young plants and I do the same for those furnishing the tubs.

I might also mention that I have also filled some tubs of ivy-leaved pelargoniums (Mme. Crousse), in a similar manner. For these my plan is to put three cuttings in a 3in. pot in late July, and to grow these along without division, tying the growths tightly together and not pinching or disbudding them in any way.—WILLIAM F. ROWLES.

A SHRUB WORTH GROWING: COROKIA VIRGATA.

SIR,—The profusion of species from which amateurs have to make choice is now so vast that it is desirable that none but the best in each genus should be recommended. I I do not think "B." would have written so favourably of Corokia Cotoneaster (page 451) if he were acquainted with C. virgata, which is much superior to it. It has not the contorted growth of C. Cotoneaster, the habit of the plant being upright, with straight stems and branchlets. I do not know how high it may grow, it is now over 8ft. here and is a pretty object when crowded with yellow starry flowers in May, to be followed by yellow berries.

The late Mr. T. F. Cheeseman, in his "Flora of New Zealand," describes only three species, but adds that he had collected "what may prove to be a fourth species . . . a twiggy bush, 6ft. to 12ft. high, not tortuous. . . . Flowers and fruit not seen." This has now been identified as C. virgata and is figured in the *Botanical Magazine*, t. 8466.—HERBERT MAXWELL, *Monreith*.

LORETTE SYSTEM OF PRUNING.

SIR,—It would be very interesting to know if any of your readers have tried the "Lorette" system of pruning. It has been tried with some success here with apples and pears. Stone fruits I have not troubled about as yet.

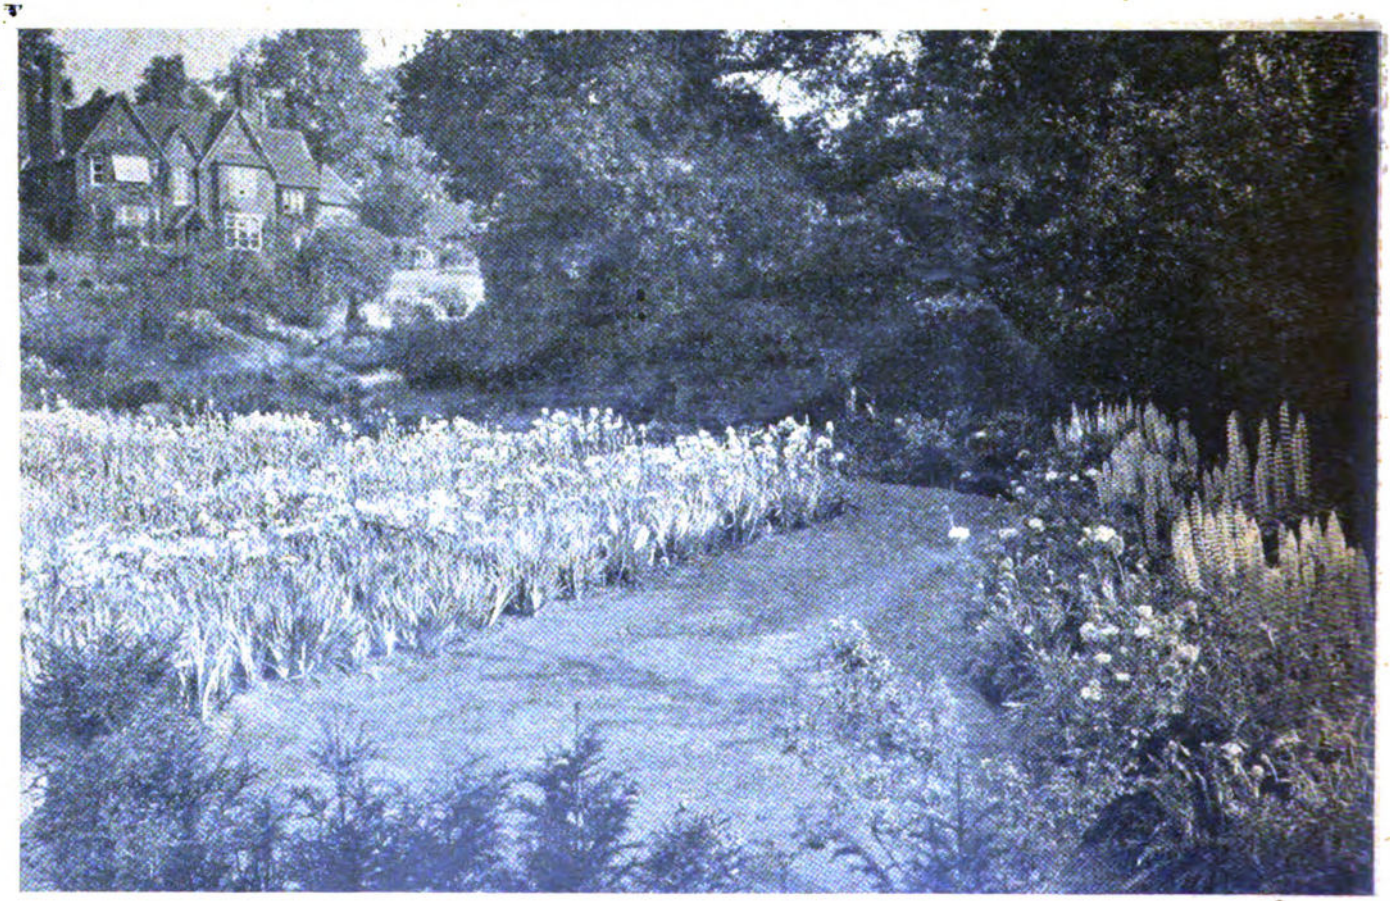
I find that young trees pruned straight into the system do well, older trees must be taken over three years to get them into the "Lorette" system, but we find a marked difference in the fruiting and growth of the different methods.

One thing especially in the system of cutting the bark close to a dormant eye, to get growth in espaliers, cordons, etc., is very successful. The time of pruning mentioned in the book on the subject must be retarded quite a fortnight in this district.

I should very much like to know if any of your readers have tried it and with what success.—H. IMPEY (gardener to Colonel D. C. Phillott), *Felsted*.

OUR PHOTOGRAPHIC COMPETITION

This week we publish several photographs showing various ways by which the surroundings of the house can be made attractive. Each photograph illustrates a different treatment, and shows how the owner in each case has attempted to create an arrangement that is not only uncommon, but which greatly adds to the appearance of the house itself. A garden should always be, as far as possible, in keeping with the house. The treatment of the immediate surroundings of the house often proves a problem to many amateurs. These illustrations, accompanied by personal notes, may serve to furnish ideas and assist those who desire to beautify the precincts of the house. Other readers have, no doubt, photographs of other arrangements which they have carried out successfully. These, if published, would serve to widen this field still further, and indicate other ways of creating an effectives urround. For this reason they will be welcomed for our competition pages.



This photograph illustrates a pleasant association of irises and lupins. A grassy border of irregular width separates the two borders and leads round the corner of the shrubbery and rockery up to the house. The lupin and poppy border which bounds the iris garden, and whose inmates flower at the same time as the irises, greatly adds to the display in early summer. This year it has been particularly fine, and it is a combination which many amateurs should try in their gardens for a colour display in June and early July. **The guinea photograph**, *sent in by* F. ROBINSON, *Uplands, Sandhurst, Berks.*

Digitized by Google

This photograph shows the beginning of a dry wall, which is being built between two lawns of a different level. This part which is illustrated was made about sixteen months ago, and shows how well antirrhinums, nepeta, dianthus, and sedums will grow in such a position. Rather heavy loam with a very little leaf-mould with burnt rubbish incorporated was used as a binding between the stones. The display during July is most effective and greatly adds to the appearance of the house. MISS R. TOCEHURST, *Tenterden, Kent.* Award of 5s.

That quite an attractive garden can be made in a short time is shown by the accompanying illustration. The garden is the result of about a year and a half's work, and was carried out entirely by myself. The ground was of virgin grassland when I took possession. The soil is light with a gravelly subsoil. The lawns were raised from seed, while the majority of the flowers were also grown from seed. The total cost of making the garden was about £20, including the making of the paths R. C. RIDGWELL, *Hornchurch.* Award of 5s.

A porch, if suitably surrounded with plants, can be made to look most attractive. This photograph, taken last month, shows how many shrubs can be used effectively even in a small garden. A wistaria drapes the entrance to the house, while in the shrubbery border are Ceanothus Veitchii, hardy fuchsias and Veronica salicifolia. A tree peony can be seen in the foreground. The brick path with the narrow edging of rock plants gives a finish to the entrance. Altogether the effect is a most pleasing one. MISS A. DUNELL, *Norwich.* Award of 5s.

When I took possession of this small garden three years ago, the view here shown was a chicken run with the usual assortment of fowl-houses, wire fencing, etc., backed by a bare brick wall. The small rock garden has been built up with local stones picked up at odd times, and is now to me a pleasure to look on. In contains a good assortment of rock plants, saxifrages, sedums, campanulas and many others. At every season of the year there is something interesting to look at. It afforded me an immense amount of pleasure in the making of it. J. DURSTON, *Wellington, Som.* Award of 5s.

THE FRUIT AND KITCHEN GARDEN

Vegetables in August.

VACANT ground should be planted with late broccoli, savoys, colewort, etc. Two fine varieties of winter cabbages to plant now are Rosette colewort and the Heartwell marrow. In late districts sowings may be made for the main crop of next year. Sowings of winter spinach and globe turnips may also be made in rows 12ins. to 16ins. apart and about 1½ins. to 2ins. deep. If the soil is very dry, it will be an advantage to water the bottom of the drills before covering the seed. Endive and lettuce may be sown broadcast in beds to be transplanted out when the seedlings are just large enough to handle.

Crops of shallots and garlic still in the ground should be taken up and dried before storing them. Sow radishes and small saladings for successional crops.

In northern districts onions should be sown early in the month for spring and summer use. Sow rather thicker than for spinach, lest the onion fly prove troublesome. Autumn-sown onions often succeed in gardens where spring sowings are generally a failure.

When digging potatoes it is a good plan (followed by many thrifty old gardeners) to select good seed-sized tubers and green them in the sun. I have heard it said that "greened" potatoes do not store so well as ungreened ones. But that is not quite true. It depends upon the method of storing. Greened tubers in bulk, as in clamp, pie or pit, are certainly more apt to "heat" and go bad than ungreened; but greened tubers put up in boxes and stored away out of reach of the winter's frost keep very well, and sprout vigorously in the springtime.

Earth up celery, etc., and keep the hoe at work among all growing vegetables. Water and mulch if required.—J. W.

How to Plant Cabbages.

IT is essential for the amateur to pay strict attention to a few important hints concerning the planting of cabbage and kindred plants. In the first instance, the plants should be a fair size when removed from the seedling bed. As far as possible, planting should be done in showery weather or immediately after a good rain.

The tap root of each plant should be nipped off as indicated in Fig. 1 of the accompanying illustrations at point marked X.

Mistakes are often made when actually planting the cabbage. For instance, it is quite a simple matter to leave the cabbage planted as indicated at (A), Fig. 2. This is incorrect, since an air space is formed into which probably more than half of the root projects. The mistake may easily be avoided if a hole is first made with a dibber, into which the plant is inserted, afterwards taking care to push the soil well round the root,

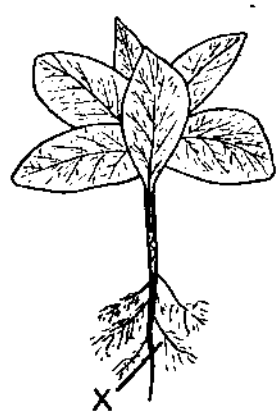

FIG. 1.—NIP OFF THE TAP ROOT WHEN PLANTING.

so that no air space is formed, as indicated by (A). The plants should be well bedded, as shown by the second view (Fig. 2), the air space being absent. In cases of considerable periods of dry weather, the plants should be set out as indicated by Fig. 3 (B). A recess is first made by scouring round with the dibber and planting then done in the usual way in the bottom of the recess, as clearly indicated at (B), Fig. 3. When planting in very wet soil, it is good policy to mould the stem as indicated at (C), Fig. 3.

By paying attention to details of this kind, the plants will make better progress than they otherwise would do.—W. J. SAUNDERS.

Selecting and Storing Seed Potatoes.

SEVERAL diseases cause the potato plant to produce small tubers, and, as these cannot be distinguished in bulk, I invariably advise the careful grower to select his seed when the crop is in growth, *i.e.*, to mark down a row or more of healthy plants from which he will eventually select his seed sets. Again, the latent energy of immature tubers is so universally recognised that it is a very good plan to "lift" the plants selected before the haulm dies down; in this way the small, hen's-egg sized tubers which he lays aside are immature. Needless to say, no scabbed seed should be saved; the best seed, in all cases, is the best guarantee of a good crop next year. Having obtained his requisite seed for next year plus a small margin in addition, the next thing is to "green" the tubers; they are left exposed to sun and air for three or four days to toughen the skin and to become green. At last they are ready for storage—in trays, in a special clamp, or in a box or bag within the ordinary clamp, but in all cases safe from frost.—CLYDESDALE.

When Summer Pruning.

THERE is one little point which should never be overlooked when the summer pruning of fruit trees is in progress. That is, to avoid the too great exposure of developing apples, pears, etc., to the light. Experience has shown that growing fruits are much better for being somewhat heavily shaded by leaves. To let a sudden flood of hot sunshine on the immature fruits will bring about a hardening of the skin, which will make it much more difficult for the specimen to expand to its proper size. When the fruits are fully grown the more complete the exposure the better, for, at this time, sunshine plays an important part in ripening and generally improving the flavour of the fruit. —L. B.

Stopping Outdoor Tomatoes.

AT the end of July and during the early days of August the cultivator should very closely examine his outdoor plants. A few trusses of fruits have set well on the more forward plants and, owing to the recent rains, the plants are making much growth of stem and leaf. Well balanced plants will not require any special attention, but all will need stopping forthwith. But the very strong specimens must have the tops pinched off immediately above the last truss of flowers formed. Owing to the strength of the plants the latter should ripen the resultant fruits very well. The more weakly plants should be stopped at the joint just above the last truss of fruits formed, because it will be enough for the strength of these plants to ripen the few fruits they bear. In each case, from the early part of August, every small side shoot should be

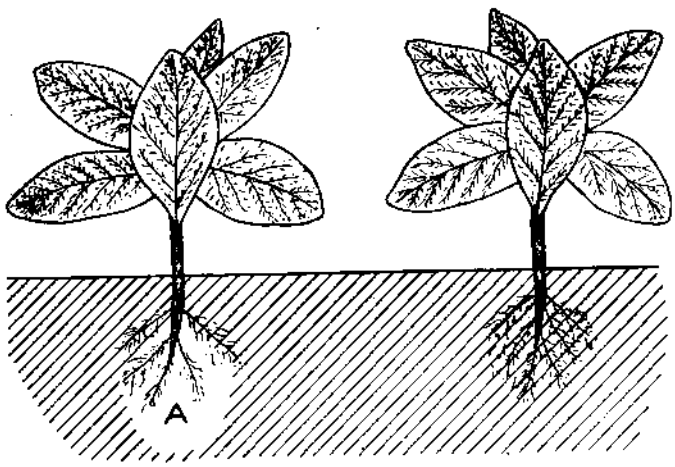

FIG. 2.—THE WRONG AND RIGHT WAY TO PLANT OUT CABBAGE.

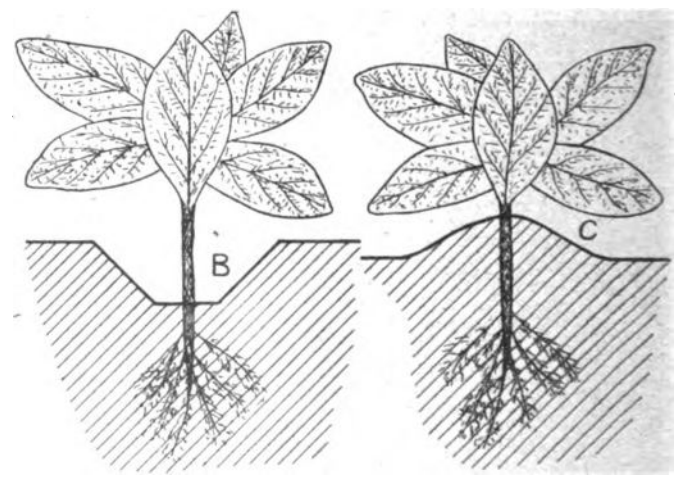

FIG. 3.—HOW TO TREAT THE PLANTS WHEN PLANTING IN DRY AND WET SOIL RESPECTIVELY.

Digitized by Google

rubbed out weekly. If the plants are not stopped they will continue to grow and form huge heads of foliage and flowers, also tiny fruits; but none of the latter will ripen, and all this superfluous growth will have robbed the plants of much-needed nourishment and then have to be cut away and discarded. If the weather is dry and hot, manure water may be applied; if it is dull and wet, a little artificial manure will be the most beneficial.—CHRISTCHURCH.

Jerusalem and Globe Artichokes.

THESE are two valuable vegetables and are much neglected by cultivators generally during the summer months. The tubers of the former may be lifted and stored in the autumn, or they may be left in the ground. The succulent heads of the globe artichokes are gathered every summer regularly, but the plants are rarely helped in any form. How seldom do we see Jerusalem artichokes earthed-up like potatoes, yet this operation is beneficial and should be done now. Draw up soil to both sides of the row, then the plants will retain their basal leaves longer and the tubers will swell better. Weakly plants can be much benefited now by lightly forking in some rotted manure on both sides of the row prior to the general earthing-up. Globe artichokes are much strengthened by weekly applications of liquid manures and by surface dressings of rotted manure. Furthermore, as the leaves are of a spreading nature, ordinary rainwater rarely saturates the soil immediately under them—only the centre of the plant receives the water. Copious waterings from the can will help the plants to swell up the heads and the scales composing them will be more succulent.—GEO. GARNER.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints (which should not exceed 150 words in length) is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

Hints on Flower Show Table Decoration for Amateurs.

1.—Some time beforehand choose flowers and suitable bowls or vases with supports. Clean and polish.

2.—Mixed colours, if well chosen, are usually more attractive than single colour schemes.

3.—Gather young flowers overnight after sundown and put in cold water in dark cellar.

4.—If possible take flowers to show tent in water. Allow sufficient time to arrange (one hour).

5.—Aim at lightness and freshness. Table should be covered (*i.e.*, do not allow for places set).

Centre bowl should be higher than surrounding vases for best effect, though not high enough to obstruct view. Foliage light and in keeping with flowers.

Flower heads or foliage are usually more effective than a table centre on the compulsory white cloth.

6.—*Colour schemes.*—Shades of lemon, orange, red and russet. Orange and delphinium blue, etc.—E. H.

Damping Off of Herbaceous Calceolarias.

To avoid damping, which often occurs in the seedling stage, I find nothing better than shifting them several times when small, instead of pricking off singly as soon as the second pair of leaves appear, I prefer placing them in small pans in bunches, three or four together in rich soil with plenty of crushed bricks mixed with it until a little more root is made. A cool frame facing north is best for these subjects. Plunge the pans in sand or sawdust to conserve moisture. A tiny frame within a frame is ideal at this early stage of growth. The idea is to keep the seedlings on the move, without giving much water, as this tends to sour the soil. Once watered, then use the syringe.—F. W.

Tamarisk Cuttings.

I recently had occasion to propagate a quantity of tamarisk. This, by the way, is an excellent low shelter plant for exposed seaside positions. I first tried to strike cuttings from the young tips, but the result was not satisfactory and hopelessly slow. I therefore cut up some older stems, choosing those about a quarter of an inch in diameter, into three inch lengths. These were inserted in sandy potting soil and given a little bottom heat over the greenhouse pipes. Every one struck, and what is more, the subsequent growth was compact and dense.—H. D.

A Home-Made Incinerator.

A very cheap but effective incinerator for burning all kinds of garden refuse can be constructed from old pieces of fairly strong wire netting. Take a strip of netting 2ft. to 2ft. 6ins. wide and about 7ft. long and bend round to form a cylindrical shape, fastening the two ends together by overlapping slightly and threading through some fairly stout wire. Form a bottom with another piece of netting cut roughly to shape and fasten to the upper portion already constructed by threading wire through the adjoining edges. Stand the contrivance on four bricks and it is ready for use. After a fire has been started with paper and wood or dry rubbish, quite damp refuse will burn in this incinerator, particularly if a breezy day is chosen for the operation.—L. K.

Making Liquid Manure in Small Quantities.

Now that liquid manure is in demand as a stimulant for all fruit and flowers, those who are not fortunate enough to possess an old cask will welcome the following hint:—Remove rose from watering can. Three parts fill the can with stable manure (failing that, horse and/or cow dung) add a spadeful of weathered soot, fill up with water (rainwater preferred) and allow to stand a few days. Raise can on some structure and place brick at rear to tilt can forward, when the liquid will pour freely from the spout, free of all solid matter, and can be caught in a bucket. By continually adding water to the manure, several gallons of excellent liquid are obtained. The residue is useful for cucumber or marrow beds, mulches for fruit trees, currant bushes peas, etc.—F. B.

Treating Autumn-Sown Onions.

At this time of the year autumn-sown onions (Tripoli) are apt to run to seed, and in some instances more than 50 per cent. will bolt and be spoilt. A very simple and effective remedy is to take a sharp-pointed knife and pierce the stalk of every seed onion about half-way between the bulb and the green, 1½ins. long. The seed stalk will then grow through the cut and continue to grow on the side of the bulb without stopping the growth of the bulb. Every onion thus treated will bear comparison with any onion that has not gone to seed.—E. H.

SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with each enquiry.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Pruning Lilacs.

I have some lilacs which have been allowed to overgrow badly, and also some young lilacs 5–6ft. high. I wish to cut my old lilacs down to decent size, and to keep my young lilacs at their present height of 5–6ft. How do I prune, and when?—E. L., Wilmington.

We advise you to cut down the old main stems to within 3ft. to 4ft. of the ground at the end of March. It is too late this year to do anything other than shorten very long shoots and cut out thin, weak stems. Thin the new growths of the young bushes now if numerous, removing the weaker. In subsequent years shorten several of the longest branches immediately the flowers fade, to maintain the desired height.

Frost Damage to Apples.

Please tell me what is the matter with the enclosed apples, that are scored around the stem. They are Bramley Seedlings, and nearly all, not a large proportion, that I have found in this condition are ones of pairs of apples from the same eye. In January I sprayed with "Mortegg," and at the fall of the blossom with arsenate of lead, for Codlin moth, of which, so far, I have seen no trace—a most unusual thing, which I put to the credit of "Mortegg." I discovered this defect when thinning the fruit. Some of the leaves of my Bramleys are infested with fly, which has curled the foliage and turned them scarlet in colour. I expect I missed them when syringing in January.—J. T., Woodford.

The scars on the Bramley's Seedling fruits sent for our examination are not caused by any kind of pest or disease, but by frost. It is a very curious trouble and one seldom seen. It occurs this way: Rain or dew settles or is collected in the calyx—the eye or flower end—of the fruitlet when it is quite tiny. Frost comes, freezes the water or dew, and so injures the skin of the fruit where it has been frozen. Hence the scars, which, as the apple increases in size, become more marked and cracked, as in the sample sent. Bramley's Seedling apples, having a large, cup-shaped "eye" in the young stage, suffer more than do most varieties from this trouble, the "tight eyed" Codlins and the like seldom, if ever, suffering. It is not a trouble you can avoid, and, fortunately, it is only in seasons when late frosts are rather severe—as in this year—that damage of this kind may be anticipated.

Remedies for Rose Mildew.

Will you kindly let me know what is the matter with the enclosed rose leaves, and the remedy? They have, of course, a touch of mildew, but the other trouble seems more like blisters than the usual "black spot." Only a few of my rose trees at the bottom of my bed are in this condition. I have had a certain amount of black spot in my roses for the last year or two, developing later on in the season, and I have picked off all leaves and used Mr. Murrell's black spot remedy in the early spring; but I do not feel convinced that the present trouble is the same thing.—M. F., Townhope Hereford.

Many of the spots on the rose foliage are due to an early attack of mildew. Others are due to a fungus which causes "leaf scorch." There are two remedies which can be tried, which are as follows: (1) Spray the foliage

Digitized by Google

with liver of sulphur, ½oz., soft soap 1 oz., and water 1 gallon, in spring when the leaves are half-grown, and repeat several times at intervals of ten to fourteen days. (2) Remove all diseased leaves remaining on the bushes in autumn, and collect all leaves which have fallen to the ground and burn.

Roses for Arches.

Will you kindly advise me as to the best rose trees for an arch over a gateway, and also three rustic arches 4ft. wide in the garden? The situation is rather exposed on the south coast, but sunny, and the soil is good. They must be strong growers. Is it better to have the same kind on each side of the arch, or two kinds to mix?—C. E. L., Walton-on-Thames.

The most suitable roses for the arch over gateway are as follows: American Pillar, Paul's Scarlet Climber, Excelsa, Albéric Barbier. For the arches in the garden we should advise you to try Emily Gray, Jersey Beauty and Hiawatha. We should not advise you to mix the varieties.

Propagating Clematis.

Will you kindly tell me the correct way to propagate clematis—the hardy climbing species? I wish to increase the stock of an old plant of a very unusual colour.—P. L., Woolpit, Suffolk.

The most successful way of propagating clematis is by taking what are known as internodal cuttings—that is, cuttings half-way between two joints. One cutting should contain at least two nodes, and they may be inserted in a sand frame with mild bottom heat, either next month or in August. After rooting, the plants can be placed in pots and grown on there until required for permanent planting. When planting out clematis it is inadvisable to spread out the roots; they are best planted in a ball.

Insect Pests on Pine Trees.

Could you kindly tell me what is attacking young shoots of Pinus sylvestris and P. austriaca (enclosed), and a remedy? Very many trees are attacked out of a plantation made in December, 1925. Trees 2ft. high, many weakened by the planting. Pest now noticed on the young shoots after a long spell of dry weather.—I. C., Bath.

The pine shoots sent for our examination are attacked by the larvæ of the pine shoot tortrix moth, Retinia buoliana. The only remedy is to pick off the injured shoots, in which will be found encased larvæ and pupæ, about the middle of June, before the moths emerge, and burn them. This has the effect of diminishing attack the following year.

Clematis montana which does not Flower.

Could you give me advice about my plant of Clematis montana. For the last two or three years the buds have all been ready to burst open when suddenly they have turned brown and dropped off. It is most disappointing as the clematis is sheltered and faces south. Previously it used to be a mass of flowers.—E. S. G., Ilkley.

It is possible that your plant of Clematis montana has rather impoverished the soil and needs a liberal mulching with manure. Climbers against walls often suffer for want of water. Unless the wind blows direct on to the plants, very little rain will reach within a foot of the stems of the plants. Water freely and also give liquid manure when the mulch is exhausted.

Unhealthy Gooseberry Bushes.

What is the nature of and cure for the disease which has attacked my gooseberry bushes? They were planted in November, 1925, and have shown the brown marks on leaves and fruit each year, and make but little weak new growth.—H. E. B., Dawlish.

There is no disease attacking the berries or leaves of your gooseberry bushes. The browning of the leaves and the berries is caused by a shortage of either potash or nitrogen in the soil, perhaps both. You will find that a spring application of sulphate of potash and a good manure mulch applied in late March each year will do much to eradicate this discoloration, though it may be a season or two of continued treatment before the soil is sufficiently improved. Of course, some varieties of gooseberries normally have the red blotching or streaking on the berries just as in the sample sent, though the small, wizened berries are typical of potash-starved bushes. Feed the bushes well—if only with the annual manure mulch—and we feel sure the trouble will disappear in a season or so.

Treatment of Apple Affected with "Scorch."

I am enclosing some leaves from a Claygate Pearmain apple tree (seven years old). Could you tell me exactly what is affecting them and, if possible, suggest a remedy, immediate or in the future? The trouble has developed within the last few days, and many of the leaves are now affected. The tree, however, looks otherwise healthy, and is bearing fruit fairly well for its age.—H. B., Newton Abbot.

There is nothing much wrong with the apple leaves you send. The brown blotching and discoloured patches are what is commonly called "scorch," probably due to lack of potash in the soil. You will find that a spring application of sulphate of potash will do much to remedy this failing. You should also lay a good mulch of stable or farmyard manure on the soil over the tree roots in spring each year, and if this has not been done it could very well go on now. It will certainly promote more healthy foliage. There is just a trace of the common apple mildew on the leaves. It is little use spraying to control this trouble—at any rate, at this stage—and the best plan is to cut off and burn all shoot tips thickly coated with the white powdery mildew and prune the trees hard in winter, so that diseased wood is removed and burned. If these points are attended to you should have little further trouble with the tree.

Lilacs from Cuttings.

I wish to obtain some lilac bushes from one I have in London to take down to Sussex. The bloom is a regular cone shape, and the leaf slightly larger than the ordinary lilac. Would it be possible to strike from slips, or how would you recommend this being done?—E. G. T., North London.

Lilac cuttings should be inserted early in July in pots of sandy soil. They should be placed in a heated propagating case or covered with a bell glass, shaded from the sun and kept moist.

Transplanting Anchusa and Pruning Roses.

I should be glad if you would give me information on the following points: (1) Can you divide anchusas, and, if so, in what manner and when? Can they be propagated from cuttings? (2) How should one prune a climbing hybrid tea rose such as Lady Waterlow and a Wichuraiana such as Dr. Van Fleet?—W. M., Bromley.

The anchusa may be divided in the autumn. Propagation by cuttings is not very satisfactory, nor is it easy of accomplishment. A climbing hybrid tea rose is pruned by removing, entirely, all very weakly shoots and any old wood over two years. Weaker shoots should be pruned back to two eyes, stronger ones to four. Prune, in your district, early in April. Wichuraiana roses should have very weakly shoots entirely cut out and the unripe ends of the others—those retained—cut off.

A Clematis for a Greenhouse.

I should be much obliged if you will kindly inform me if there is a species of clematis suitable for growing in a cool greenhouse under a grape vine.—A. H., Ealing.

A suitable plant for the position you mention is Clematis Armandii.

Trapping Moles.

Can you tell me what is the best way to deal with moles? My garden is a new one, surrounded outside my fence by open fields. I am uncertain whether the moles come in from outside, or whether they are actually in my garden. Anyway, they are making a mess of the borders with their tunnelling. I read that calcium carbide placed in the runs got rid of them, but this measure has had no effect, though I opened up several runs and placed the carbide in position.—S. L., Blackpool.

Undoubtedly the best way to get rid of moles is by trapping them. The traps should not be placed in the vicinity of the mounds, but the small runs should be traced back as far as possible to what you consider to be the main run, and the traps placed there. The main run can generally be detected by the ground being as hard as cement. This can be felt by pushing a thin wire into the soil. Probably you will not be able to detect this yourself, but an expert mole catcher should be able to do so. The idea of placing traps in the main runs is that a number of moles would be caught in this way, while in the small runs only one or two of the animals would be caught. Wooden traps are usual, but there are now some metal traps on the market, obtainable from horticultural sundriesmen advertising in this paper.

Treatment of Asparagus Beds.

Our asparagus was not at all a success, either this year or last. What is the best dressing for the beds, now that we have finished cutting? When finishing up beds for winter we made the earth fine and then placed a thick layer of horse manure on top. My present man reverses the order, and puts a thick layer of manure and earth on top of this. It seems to me that on this heavy land the beds are never fine, as manure is left on, even when supposed to be taken off before growth is starting in spring. I shall be much obliged for your advice.—K. M., Herts.

As your soil is naturally heavy, the best course to take would be to apply once a week until the end of August a good soaking of liquid manure, to feed and strengthen the growing plants. When the ripe "grass" has been cleared away, apply a light dressing of littery manure with a sprinkling of fine soil on the top simply to keep the manure in place; the litter is to keep the roots of the plants secure from frost, and can be removed in due course.

Quick-Growing Creeper for Trellis-Work.

I have some trellis-work facing east, and also some in a more sheltered position. I want to train something up them, and should be glad if you could give me a little advice. The growth is intended in each case to hide a door, and I am wishful to plant something which would bear foliage during the winter. As I am anxious that the doors may be hidden as soon as possible, a quick-growing creeper would be preferable, if you can suggest one.—J. B., Kendal.

For the trellis-work facing east, we would suggest that you plant Lonicera Halliana, a fast-growing evergreen honeysuckle. In the more sheltered position, Escallonia langleyensis would be a useful and attractive evergreen with rosy red blossoms.

NEW SEEDLING ROSES

IT was hoped that the special show of new roses which was held by the National Rose Society at the Horticultural Hall on Friday, July 15th last, would bring forth some new seedling roses of noteworthy perfume. It will be remembered that last year the *Daily Mail* gave the Society a valuable gold cup to be awarded to the raiser of the best new fragrant rose, and that the judges considered none of the novelties sent in competition was of sufficient merit to justify the award of the cup.

The offer of the cup was repeated for the Show under notice and the conditions were altered slightly. The chief condition was fragrance. The selected rose might be of any class, provided it was raised in Great Britain and Ireland, but it must have fragrance. As we all know, fragrance is an elusive quality and, to paraphrase, "every nose forms its own fragrance." Unanimity on such a point could scarcely be expected, but it was interesting to find that outside the ranks of the official judges, the majority of those who may be considered competent to form a reliable opinion were agreed that they would have selected several others of the new roses in preference to the judges' choice.

Altogether there were nearly a hundred new roses to be seen, and it is safe to state that never before have so many new seedlings been gathered together. Over sixty of them, shown under numbers, were in competition for the gold cup and all were eligible for the Society's medal awards. As may be expected, there were roses of all classes, from the ideal perfectly formed hybrid tea rose to the small flowered cluster variety, with single roses, coarse hybrid teas, of cabbage shape and almost cabbage size, and shapeless roses in between. Many had a pleasant perfume that was readily perceived, while in others it required imagination to attribute that precious gift of fragrance to them.

While we do not agree with the findings of the many judges appointed by the Council, and we suspect they did not agree among themselves, we appreciate that the award was the result of a prolonged consideration of all the possible claimants, to the honour and the gold cup, which was awarded to a crimson hybrid tea variety which we conclude is to be known as the "*Daily Mail* New Scented Rose." It was raised by Messrs. W. E. B. Archer and Daughter, whose charming single pink rose, Dainty Bess, was awarded a gold medal at the autumn rose show of two years ago. The new rose is stated to have been raised from Château de Clos Vougeot and K. of K. It is somewhat like the former variety, but very like Etoile d'Hollande, which, in our opinion, is a more fragrant rose. Of the scented roses, our choice would have been Portadown Crimson, a well formed crimson hybrid tea, heavily flushed with maroon, shown by Messrs. S. McGredy and Son. No. 25, shown by Messrs. B. R. Cant and Sons, was another fragrant rose. It is of rather more than average size, goblet shape and stippled with bright pink. No. 37, a hybrid musk rose, shown by Mr. J. H. Pemberton, is what is called "old-fashioned" in shape and bears plentiful clusters of flattish, pink flowers of delicious fragrance. No. 38, a pale lemon hybrid tea of good form and shown by Messrs. Alex Dickson and Sons, was pleasantly fragrant. No. 58 had a most refreshing perfume. It is a rounder, compact hybrid tea of pale flesh pink colour, deepening in the heart of the bloom, and was shown by Messrs. G. Longley and Sons.

The following is the list of new varieties which received award :—

MARGARET ANNE BAXTER.—This we considered to be the best new rose in the Show. It is a perfectly formed hybrid tea variety and appears to be suitable for all purposes. The flowers are borne on long, clean stems, the foliage is good and the plant which was shown indicates a robust and free habit. The substantial petals are white and there is a suggestion of pale flesh pink in the heart of the bloom. Gold medal. Shown by Messrs. T. Smith and Sons.

FLAMINGO.—A double hybrid tea rose of glowing rosy cerise colour and very beautiful in the bud stage, but poor when mature. It is inferior to Lady Inchiquin, which variety it resembles to a certain extent. Gold medal. Shown by Messrs. Alex Dickson and Sons.

FORTUNA.—A large single hybrid musk rose of delicious fragrance. The rounded flowers are of bright, light rose colour when first opened and pass to dull rose with age. It is free flowering, dwarf and of good habit. Gold medal. Shown by Mr. J. H. Pemberton.

Daily Mail NEW SCENTED ROSE.—A medium sized double hybrid tea variety of velvety crimson colour flushed with maroon. Similar to Etoile d'Hollande, but not quite so fragrant. Gold medal and gold cup. Shown by Messrs. W. E. B. Archer and Daughter.

FRANK READER.—A handsome fully double hybrid tea variety of good form, large size and pale creamy yellow colour, deeper at the base of the petals and tinged with apricot at the heart. It received the R.H.S. award of merit on July 13th, 1926. Certificate of merit. Shown by Messrs. D. Prior and Son.

GEORGE HOWARTH.—The recognition of the merits of this glowing rose, flushed scarlet hybrid tea is somewhat belated. We recall admiring it at the autumn show of last year and previously. The flowers are of medium size, freely produced, and there is a touch of gold at the base of the petals. Certificate of merit. Shown by Messrs. Bees, Limited.

PORTADOWN CRIMSON.—As we have already remarked we consider this the most fragrant new rose in the Show. It is a medium sized rich crimson hybrid tea, flushed with maroon. Certificate of merit. Shown by Messrs. S. McGredy and Son.

LADY LESLIE.—Like Flamingo, this variety is at its best in the earlier stages and then it is very handsome. The well formed blooms have broad substantial rosy cerise petals, but the colour of the outer petals all too soon becomes tinged with magenta. There is a curious short vertical line of gold on the middle of each petal at the tip. Certificate of merit. Shown by Messrs. S. McGredy and Son.

COMPETITIVE CLASSES.

The various classes in which any roses might be displayed were a very attractive feature of the Show. The groups arranged on separate tables were all of great merit, and the quality of the many flowers thus displayed was far higher than might have been expected in view of the recent inclement weather. The first prize was won by Messrs. Alex Dickson and Sons, with a particularly handsome group which was well finished. They included beautiful baskets of Lady Inchiquin, Betty Uprichard and Sunstar, supported by adjoining pillars of Lady Helen Magloona, Lady Worthington Evans and Mrs. Henry Morse. Messrs. B. R. Cant and Sons were a good second in this important class and they had a gorgeous centrepiece of Betty Uprichard and pillars of Los Angeles, Margaret Dickson Hamill, Mme. Butterfly and Mrs. Henry Morse. In his third prize exhibit, Mr. Elisha J. Hicks displayed lovely blooms of Betty Uprichard, Lady Inchiquin, Mrs. Henry Stevens and many other good roses. Mr. J. H. Pemberton and Dowtry's Roses Co., both set up admirable displays of roses.

The competition in the above class was outdone in that for collections arranged on tabling set against the wall, for no fewer than eleven firms set up collections and these made a gorgeous display. Messrs. Chaplin Bros. were first with a generous arrangement of Emma Wright, in a large basket, pillars of Mrs. Herbert Nash, Mrs. Henry Bowles and Lady Inchiquin, while in front there was a charming vase of Etoile d'Hollande. Mr. George Prince was second, and he showed excellent masses of Angele Pernet, Hortulanus Budde, K. of K., I. Zingari and Lady Roundway. The third prize was awarded to Messrs. R. Harkness and Co., for arches of K. of K., Mabel Morse and Mrs. Henry Morse, spanning blooms of other good sorts. Mr. Ernest Hicks, who was fourth, showed fine blooms of Golden Emblem, Padre, Lady Inchiquin and Frau Karl Druschki.

But good as were these roses in the groups, it was the exhibition blooms in boxes that reached the high-water mark of excellence at the Show. Messrs. Frank Cant and Co. had been winning honours at different shows with good exhibition blooms, but we question if any were so superb as those which won them the first prize on the present occasion. Their twenty-four distinct blooms were of even quality, fresh, well formed and of good size. The chief sorts were Mrs. G. Norwood, Mildred Grant, Mrs. G. Marriott, Courage, George Dickson and Gladys Holland. Messrs. D. Prior and Son were second with a good collection, which included specimens of Marcia Stanhope, J. G. Glassford, Duchess of Normandy and Augustus Hartmann.

The amateurs also earned big honours with the quality of their blooms, although there were only two exhibits of twelve distinct varieties in the open class. Mr. W. E. Moore, Ickenham, was first with a superb board of George Dickson, Mrs. Henry Bowles, Red Star, Louise Crette, Mrs. Charles Lamplough and other good sorts. Mr. H. Robins, Margretting, was second, and he included Lady Inchiquin, Mrs. Herbert Nash and Frau Karl Druschki of good quality. The best six distinct varieties were staged by Mr. L. F. Roberts, who had excellent specimens, including Mme. Jules Gravereaux, George Dickson and Mrs. C. Lamplough.

New Plants at Vincent Square.

THE Floral Committee of the Royal Horticultural Society gave awards to an unusually large number of plants on July 19th, 1927, and many of them were quite old inhabitants of our gardens.

CLETHRA DELAVAYI.—This is an exceedingly handsome Chinese shrub. The stems of the young shoots and the stalks of the flowers are reddish. The broadly lanceolate leaves are crinkled and dark green above and glaucous beneath. The round white flowers are much larger than those of any other species, and are densely set on terminal racemes. First-class certificate. Shown by Mr. G. W. E. Loder, Hawkhurst Place, Ardingley.

CARMICHELIA AUSTRALIS.—A half-hardy New Zealand shrub which has elegant pinnate leaves and an abundance of pale pink flowers. Award of merit. Shown by Mr. G. W. E. Loder.

FEIJOA SELLOWIANA.—This is a handsome wall shrub for sunny aspects in the southern and western counties. The under sides of the leaves are silvery and the flowers are myrtle-like, but much larger, and the fleshy buff-coloured segments recurve, showing the bright rosy purple insides and large cluster of filaments. When in full bloom it is a very striking shrub. Award of merit. Shown by Mr. Ingram Whitaker, Pylewell Park, Lymington.

GAULTHERIA (?) FARRER 1191.—The correct name of this attractive little shrub has to be determined. It is a spreading little bush furnished with small, alternate, ovate shining leaves which are minutely toothed, and bears relatively large berry-like blue flowers.

Digitized by Google

The large fleshy calyces curve inwards and have green centres. Award of merit. Shown by Mr. Lionel de Rothschild, Exbury, Hants.

HYMENOCALLIS SPECIOSA.—Formerly this fragrant white lily was very common in our stove houses and was known as Pancratium speciosum; but it is rarely grown now. Award of merit. Shown by Sir William Lawrence, Bt., Burford, Dorking.

LOBELIA TUPA.—This half-hardy herbaceous plant was introduced over a hundred years ago, when it was considered to be of a poisonous nature, but we have no record of any justification for this. It is a robust, handsome plant, bearing large leaves and spikes of scarlet flowers. Award of merit. Shown by Mr. G. W. E. Loder.

LOMATIA FERRUGINEA.—This Chilian evergreen is frequently included in collections of shrubs shown at Vincent Square and at Chelsea, but rarely in flower. But it flowers regularly and freely in several Irish gardens, though the short racemes of flower are mostly hidden by the luxuriance of the handsome pinnate leaves. The branches now sent show the flowers more than usual. Their structure is interesting and unusual. The disposition of the long curved pistil makes the expanded flower appear to have lost one segment, and the anthers are set in a little pouch at the tip of one floral segment. The colour is golden buff on the outside and bright scarlet within. Award of merit. Shown by Mr. H. Armytage Moore, Knowallane, Saintfield, County Down.

MITRARIA COCCINEA.—This is quite a common shrub in the warmer parts of the country and is sometimes grown as an informal hedge, when, in flower, it is especially attractive. It bears small delicate green leaves and long-stalked, bright crimson, tubular flowers. Award of merit. Shown by Mr. G. W. E. Loder.

MARANTA PORTEANA VARIEGATA. — This white and green leaved sport from M. Porteana has beautiful purple colouring on the under sides of the large leaves. It requires tropical conditions. Award of merit. Shown by Messrs. L. R. Russell, Limited.

SABBATIA CAMPESTRIS.—This is a showy American annual which becomes about 18ins. high and bears bright pink, star-like flowers which have deep yellow centres. Award of merit. Shown by Mr. T. Hay, Hyde Park, London.

TECOMA JASMINOIDES.—The award is subject to the verification of the name, which seems to be very necessary, for the flowers have much more the appearance of a thunbergia than a tecoma. It has shining pinnate leaves with the stems grooved, and bears large trusses of stippled pink flowers, which have dark crimson hairy throats. Award of merit. Shown by Mr. G. W. E. Loder.

SOCIETY NOTES

Society Meetings.

August 1.—King's Lynn Horticultural Society's Exhibition; Romsey Gardeners' Association meets; Ticehurst Flower Show; Wadhurst Flower Show, Pershore Flower Show, Slapton Horticultural Society's Show.

August 2.—Royal Caledonian Horticultural Society meets.

August 3.—Royal Horticultural Society's Show (Plums, Peaches and Early Apples); Scottish National Sweet Pea, Rose and Carnation Society's Exhibition (two days); Northampton Horticultural Society's Exhibition (two days); Royal Horticultural Society of Ireland's Exhibition (three days).

August 4.—Harrogate Agricultural Society's Exhibition (three days).

August 5.—Accrington Chrysanthemum Society meets.

August 6.—Blackburn Horticultural Society meets.

August 7.—Wakefield and North of England Tulip Society meets.

August 8.—United Horticultural Benevolent and Provident Society meets.

August 9.—Jersey Gardeners' Society meets.

August 10.—Taunton Deane Horticultural Society's Exhibition, in conjunction with the National Gladiolus Society's Exhibition (two days); Sheffield Chrysanthemum Society meets; Stonegate Flower Show; East Anglian Horticultural Society's Exhibition.

August 13.—Cannock and District Horticultural Show (two days); Highfields and District Show.

August 15.—Harrogate Horticultural Association meets.

August 16.—Royal Horticultural Society's Show, Gladioli (Foremarke Cup); Clay Cross Horticultural Society's Exhibition; Edmonton Horticultural Association's Show (three days).

August 17.—Bangor Horticultural Society's Exhibition (two days); Shropshire Horticultural Society's Exhibition (two days), Shrewsbury; North Western District Post Employees Horticultural Society's Show.

August 18.—Royal Horticultural Society of Aberdeen's Exhibition (three days).

August 19.—Montrose Horticultural Society's Exhibition (two days).

August 20.—L.M.S. Horticultural Society's Exhibition; Charfield Flower Show; Newton Heath Allotments Society's Show.

August 24.—Southport Flower Show (three days); Littlehampton Horticultural Society's Exhibition; British Carnation Society's Show at Southport.

August 25.—Dundee Horticultural Society's Exhibition (three days); Paisley Floral Society meets; Ruthin Horticultural Society's Show.

August 28.—Eppleton Colliery Welfare Flower Show.

August 29.—Royal English Arboricultural Society meets (five days).

August 30.—Royal Horticultural Society's Show.

A Cup for Gladioli.

THE annual competition for the Foremarke Challenge Cup for Gladioli will take place in 1927 at the Royal Horticultural Society's Fortnightly Show at Vincent Square, Westminster, on August 16th. The cup is offered for the best twenty spikes of named gladioli in not fewer than ten varieties. Not more than two spikes of any one variety may be shown. The competition is open to both amateur and trade growers. Entry forms may be had on application to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.1, by whom the completed forms must be received not later than by the first post on Wednesday, August 10th, 1927.

Wolverhampton Flower Show.

THE torrential rain on the day before the Show, followed by a renewal of thunder and rain on the opening morning, caused whole areas to be under water. In the marquees the mud was inches thick, boards had to be laid throughout, and as these were narrow some inconvenience was caused. The flowers, however, were not spoilt, and altogether a very fine display had been arranged. The groups of herbaceous plants and ornamental foliage in the open classes were very fine indeed. Messrs. Webb had a well staged exhibit of sweet peas in great variety, with groups of stocks, fuchsias, lilies, etc. We noticed Sweet Pea Flora All Purple, which was uncommonly good. Messrs. Baker had a formal herbaceous garden in which the plants and flowers were well and tastefully arranged. Among them being Delphinium Anne Baker, a new variety which gained an award of merit at the Royal Show at Newport last week. Messrs. Carters were showing many of their well known varieties of vegetables. Their dwarf broad bean Royal Dwarf Fan was noticeable and should become popular as a good early bean. Their new cauliflower Quality was also very good, with a fine firm flower. Messrs. Bees had a wonderful collection of delphiniums and herbaceous plants, prominent among them being their D. Cambria. Mr. Herbert was showing his new Pink Princess Elizabeth, but his Model seems to us hard to beat. Among the amateurs Major S. S. Thompson's begonias were one of the best exhibits in the Show. Lord Leconfield's collection of vegetables were very well grown and clean.

AWARDS TO BEARDED IRISES

THE great collection of bearded irises which have been under trial at Wisley for several years have been judged, and the following awards made by the Council of the Royal Horticultural Society on the report of the Joint Committee of the Royal Horticultural Society and the Iris Society. A full report of the trials will appear in the Journal of the Royal Horticultural Society.

Many varieties in the trial are still awaiting judgment, and the following is to be regarded as a preliminary list.

AWARDS OF MERIT.

White or Nearly White Varieties.—Istria, a collected form from Mr. W. R. Dykes, sent by the Orpington Nurseries, Kent; White Knight, raised by Mr. Saunders and sent by the Orpington Nurseries, Kent; Mystic, sent by the Orpington Nurseries, Kent.

White Standards, Coloured Falls.—Rhein Nixe, raised by Messrs. Goos and Koenemann, sent by Messrs. Barr of Covent Garden, Perry of Enfield and Waterer and Crisp of Bagshot.

Purple Bicolors.—Lord of June, raised by Mr. G. Yeld, sent by Messrs. Lowe and Gibson of Hayward's Heath; Leonato, raised by Sir Arthur Hort, sent by Messrs. Wallace of Tunbridge Wells; Souvenir de Mme. Gaudichau, raised by Messrs. Millet, sent by Messrs. Wallace; Titan, raised by Mr. A. J. Bliss, sent by Mr. P. L. Pilkington; Imperator, raised and sent by Messrs. Cayeux and Le Clerc of Paris; Kharput, sent by Messrs. Barr, and Perry.

Purple Selfs.—Corrida, raised by M. Millet, sent by Messrs. Wallace; Mars, sent by Messrs. Barr; Kochii, sent by Messrs. R. Veitch, and Barr; Kurdistan, raised by Mr. W. R. Dykes, sent by Messrs. Wallace.

Standards of Shot Shades.—Mary Gibson, raised and sent by Mr. A. Perry; Alcazar, raised by Messrs. Vilmorin and sent by Messrs. Waterer and Crisp; Tenebrae, sent by the Orpington Nurseries; Troades, raised and sent by Mr. A. Perry; Billia, raised and sent by Mr. A. Perry; Cardinal, raised by Mr. A. J. Bliss and sent by Messrs. Wallace; Prosper Laugier, raised by M. Vardier, sent by Messrs. Barr; Ambassadeur, raised by Messrs. Vilmorin, sent by Messrs. Vilmorin, Andrieux of Paris.

Varieties with Yellow Standards and Coloured Falls.—Marsh Marigold, raised by Mr. A. J. Bliss, sent by Messrs. Lowe and Gibson; Fro, raised by Messrs. Goos and Koenemann, sent by Messrs. Waterer and Crisp.

Yellow Varieties.—Amber, raised and sent by the late Mr. W. R. Dykes of Worplesdon.

THE

GARDEN

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2905 Saturday, August 6th, 1927 Price TWOPENCE

THE bulb planting season is fast approaching and preparations must be made this month by obtaining and planting all bulbs that are required for furnishing a decorative display either in the home or in the greenhouse. Outside plantings may be left until the end of this month and during September. Bulbs for forcing must be planted as soon as possible now to secure as early flowering as possible Among the many bulbous plants which are suited for placing in pots or bowls there is none more decorative or more popular than the hyacinth. With its stately habit noble flower spikes and wide colour range, it is a flower to be grown by all. Its culture is simple Even a beginner may succeed in growing fine plants at his first attempt Good bulbs, early planting, combined with a little attention immediately after planting are all that is necessary Cultural hints will be found given in an article on these attractive plants in this issue.

THE GARDEN

VOL. XCI.—No. 2905. AUGUST 6, 1927. PRICE TWOPENCE.

SEASONABLE WORK IN THE ROCK GARDEN

THE rock garden needs constant attention during the summer and autumn months of the year if it is to look well. The summer is the season of growth, and with the large variety of plants grown in a rockery it is very necessary that those which make rampant or excessive growth should not be allowed to swamp the slower-growing subjects. Where plants are growing vigorously and occupying more than their allotted space they should be carefully cut back. Straggly plants should also be trimmed and bushy plants thinned out.

It will be necessary to pay particular attention to watering during the hot, dry summer days. Owing to the artificial nature of the rockery, the drainage is good and the plants will tend to suffer from lack of moisture during the summer, especially as their natural habitat is one of greater altitude and, consequently, cooler conditions. The sprinkler should be set going during the evenings and, if very dry, during the early morning; or, if a sprinkler is not available, a watering through a fine rosed watering-can will do.

During the summer and early autumn the propagation of a number of the alpine plants on the rockery by means of cuttings can be effected. The best place to use as a propagating pit is a cold frame. The frame should be well drained and some good garden soil placed in to a depth of, say, 6ins., and on the top of this a layer of silver sand 2ins. deep.

As an alternative a bell glass may be used, and, if desirable, the cuttings can be placed round the edges of pots over which the bell glass is placed. Wherever possible, the cuttings should be taken with a slight heel and should be growths of 1–2ins. in length, according to the subject.

There are quite a large number of rockery plants which may be treated this way. Among them are arabis, Campanula muralis, C. pulla, C. Raineri, etc.; Iberis sempervirens, I. correæfolia, onosmas, Phlox subulata, P. divaricata, aubrietia, Androsace lanuginosa, Lithospermum prostratum, L. p. Heavenly Blue (in autumn well ripened shoots), saxifragas (encrusted and allied sorts), Veronica saxatilis, ericas, Sedum Ewersii, zauchneria, Cherianthus alpinus, Viola gracilis, V. cornuta, helianthemum (in autumn, semi-woody twigs), etc. When aubrietias have finished flowering they may be cut over and a lot of new growths suitable for cuttings will appear.

The cuttings should be placed firmly in rows in the frame and well watered in; the frame being kept close for a few days and shaded in sunny weather. When the cuttings have started to root, air should be admitted, and in a week or so after rooting they may be transferred to thumb pots for growing on. Some subjects take much longer to root than others, so that, if there are not too many plants to be propagated, a bell glass has many inducements to offer as a propagating place, since rooted cuttings in pots can be removed with but little interference to the remaining cuttings.

This Week's Work

For Gardens in the South and Midlands.

Pot up Roman hyacinths for forcing.

Place grease bands round fruit trees.

Remove spent flowers from bedding plants in order to prolong the display of bloom.

Thin late-sown turnips and prick out lettuces.

Cut out old fruiting canes from raspberries.

Start potting up lachenalias and freesias.

Strike lavender from cuttings.

Water strawberry runners regularly.

Clip evergreen hedges.

London Gardens Exhibition.

THE London Gardens Guild, in conjunction with the *Daily Express*, is again organising an exhibition of flowers at the Temple Gardens, Victoria Embankment—lent by kind permission of the Honourable Society of Benchers of the Inner Temple—on September 3rd, 4th and 5th. This will afford an opportunity for Londoners to see some of the beautiful flowers grown in the gardens entered for the recent All-London Gardens Championships (in which there were over 12,000 entries), as there is a special section devoted to the prize-winners in that competition.

The exhibition is being run on a much larger scale this year, and a very comprehensive schedule has been compiled, which includes sections for individual, as well as corporate displays by local garden societies, of London-grown flowers. This is one of the rare occasions when those outside the professional status are afforded the chance to exhibit at a great public show.

In addition to these exhibits, there will be displays from municipal authorities, and famous firms in the gardening industry will also be showing, including trade growers who specialise in plants which thrive particularly well in the London area. There will also be replicas of the prize-winning gardens.

Large gold, silver and bronze medals will be awarded for the best exhibits in each of the sections, and for each of the championship classes.

Schedules and entry forms are now available, and can be had on application to the Organising Secretary, London Gardens Guild, 124, Walworth Road, London, S.E.17

Rhododendron Association.

AT the first Council meeting of the new Rhododendron Association, the following were elected Honorary Life Members of the Association: Mr. J. C. Williams, Professor W. Wright Smith, Mr. W. J. Bean, Mr. E. H. Wilson, Mr. George Forrest, Captain F. Kingdon Ward. It was further decided that any persons joining the Association prior to December 31st, 1927, should be known as Founder Members.

We are indebted to Messrs. Sutton and Sons, Reading, for the use of the illustration which appears on our front cover this week.—ED.

This Week's Work

For Gardens in Scotland and the North.

Begin planting freesias in pots for frame culture.

Remove spent blooms from biennials and shrubs.

Pot up cinerarias and herbaceous calceolarias.

Clean up strawberry beds after cropping is over.

Begin budding roses.

Prick out late sown biennials.

Prepare traps for earwigs on dahlia plants.

Continue spraying roses for green fly mildew, etc.

Remove old raspberry canes.

Plant vacant ground with winter vegetables.

Take cuttings of geraniums, fuchsias, and hydrangeas.

Digitized by Google

HYACINTHS FOR ALL

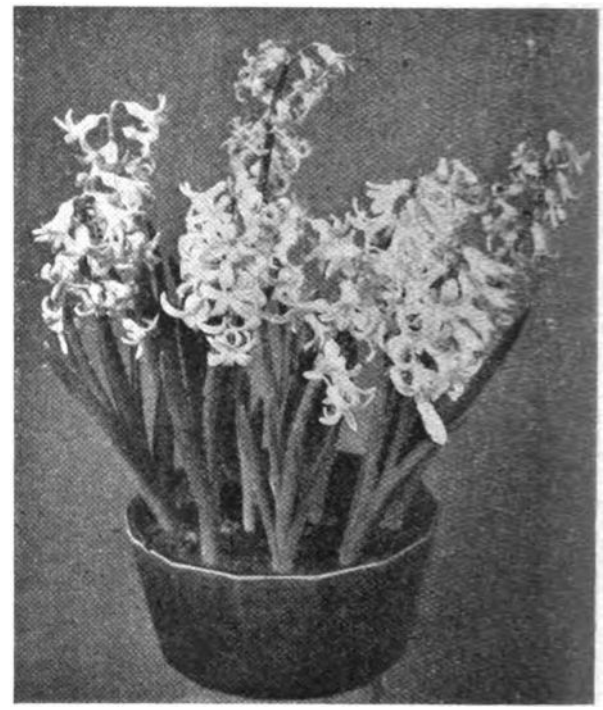
Now that the bulb planting season is approaching, preparations should be made for planting all bulbs for house decoration in winter and early spring. The hyacinth is one of the best for this purpose, and if the hints given in this article are followed, amateurs will find their trouble and expense well repaid by a brilliant show of colour and bloom indoors in the dull months of the year.

THE very name must remind each and every reader of some beautiful bed, border, pan or maybe single plant in pot or glass that has at some time fixed itself in your memory, and you fancy even now you can still feel the lingering scent of the flowers.

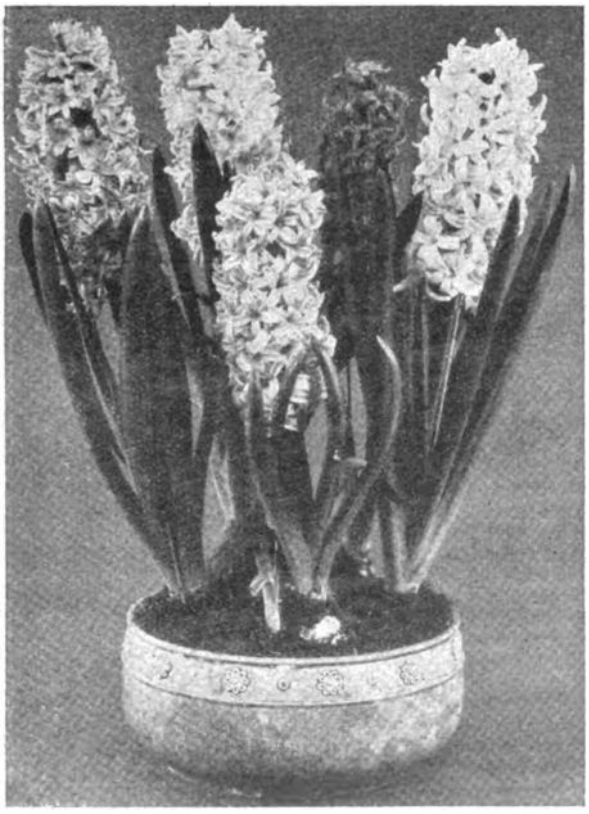
Hyacinths are considered by many to be stiff and formal subjects. They may be, but a little consideration and forethought with regard to combination of colours, and the many plants that may be used in conjunction with them, entirely removes this, shall we say, prejudice. However they are used, they are delightful; there are so many ways in which hyacinths may be grown and few plants can give such a choice diversity of colouring. So soft and clear; furthermore, the flowering season covers at least four months. First, we have the French Roman hyacinths, which can easily be flowered at Christmas, as also may be the prepared Dutch varieties. Bulbs should be procured as early in August as possible and potted up as soon as received in a good mixture of soil, consisting of rich fibrous loam, three parts, and one part each of well decayed cow manure and leaf-mould, with a quantity of coarse sand to make the whole porous; it is advisable to mix this thoroughly several days before using and then it should be moderately moist only.

Old pots, well cleaned, are much preferred to new ones, as the latter absorb so much moisture and are likely to injure the delicate roots. The soil should be pressed fairly firm round the bulb and the crown be just above the level of the soil, which should reach up to half an inch from the rim of the pot, thus leaving room for watering. When potted, place in a cool position outdoors on a bed of ashes or boards, then cover the pots to a depth of 5ins. or 6ins. with finely sifted cinder ashes or fibre. Some growers of specimen hyacinths put an inverted 3in. pot over each bulb, a small piece of slate being placed over the hole of this pot; undoubtedly a good protection from injury to the shoot by slugs or damage from the plunging material.

After the bulbs become well rooted and active growth has commenced, which will, generally speaking, be from six to eight weeks, remove to a cold frame or shelves near the glass in the greenhouse. A good plan is to cover the young growth with a sheet of brown paper for a few days to allow them to harden off gradually, as too fierce a light will injure them in their blanched state. Never bring hyacinths into full light until the flower spike is well through the neck of the bulb, or the tips of the bells will become green and spoil their full development. Do not at this stage allow them to suffer from an insufficiency of water; as soon as the bells begin to raise themselves to a horizontal position and show colour, liquid manure, well diluted, with a little soot added, should be liberally given. Support the spike early and shade if necessary.



THE CYNTHELLA OR MINIATURE HYACINTHS SHOULD NOT BE OVERLOOKED WHEN PLANTING THIS SEASON. *They make charming plants for pots or bowls.*



A DECORATIVE BOWL OF MIXED HYACINTHS. *Nothing looks more attractive in the house in early spring than a collection of hyacinths in flower.*

We will mention the names of a few varieties which will grow freely and with a minimum of attention. L'Innocence, British Queen, La Grandesse (pure white), Lady Derby, Moreno, Queen of the Pinks (pinks) General Pelissier, King of the Belgians and La Victoire (reds), Dr. Lieber, Grand Maitre and Myosotis (blue), Marie and King of the Blues (dark blue), City of Haarlem and Yellowhammer (yellows), Lord Balfour and Sir William Mansfield (mauves). These are some of the best for general purposes, but should a few choice sorts be desired, we may mention the following: Queen of the Whites, Salmon Queen, Orange Cerise, King of the Reds, King of the Blues, Ivanhoe, (dark blue), Orange Boven, Prince Henry (deep yellow), and Remembrance (reddish mauve).

The cynthella, or miniature, hyacinths must not be overlooked as they make charming subjects for growing in china or fancy bowls in prepared moss fibre or furnishing window boxes, etc. Batches may be grown in shallow boxes for successional plantings, as the plants may be transferred from one receptacle to another. If this be carefully done and the roots not damaged, they are not in the least affected by the removal.

It may be as well here to mention that prepared moss fibre will absorb a lot of moisture, and it is advisable to lay it out and sprinkle with a water can, rain water preferable, for several days before using, turning the fibre over many times until it is thoroughly moist right through.

Nothing is more bright and pleasing in the spring than a nice bed or border of hyacinths, and there are so many beautiful tints to choose from that it is possible to suit any taste. Small beds are best planted with one shade only, but the larger beds can be laid out in designs of contrasting colours or again with two colours planted alternately, such as dark and light blue, cream and dark blue, or white and pale pink; in fact, there is no limit to the beautiful combinations that may be used, and very charming is a groundwork of myosotis, silene or double white arabis. Polyanthus, violas, alyssum, iberis, saxifrages and primroses are also very useful for this purpose and help to give a finish to the arrangement. Hyacinths may also be planted alternately with narcissi, an arrangement which produces a most graceful effect.

When a carpeting is used to the beds of hyacinths, care will be necessary in selecting colours that will harmonise properly. It is also necessary to allow the hyacinths an additional amount of space so as to show off the groundwork adequately.

Hyacinths in the borders are very effective either planted in long sweeping lines in double rows, all of one shade, or in groups of mixed dark blues, light blue shades, rose and pink or red shades.

For bedding, 9ins. to 12ins. apart is a good distance to plant, and the bulbs should be covered with soil to the depth of 4ins. to 5ins. above the crowns. The number required for a given area, however, must be determined by local conditions and the object

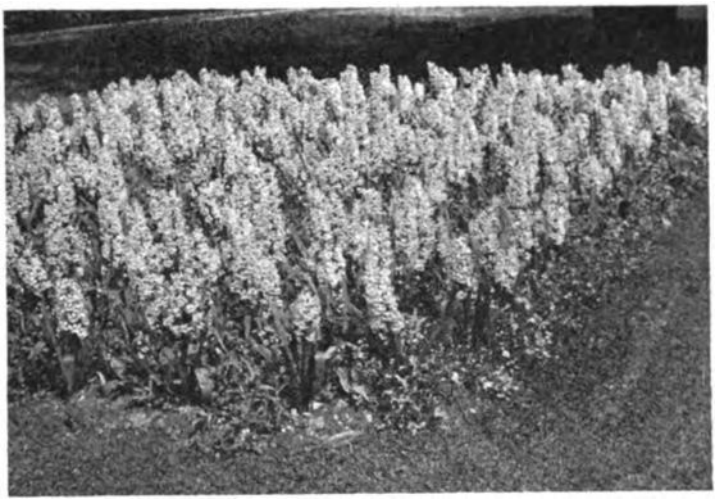
Digitized by Google

in view; a large bed in the distance need not be so closely planted as a small bed in the immediate foreground, and, of course, a smaller number will be necessary in either case if a groundwork of myosotis, silene or arabis be provided.

One thing to remember is that the hyacinth is a hardy subject and does not need to be coddled; perhaps the most injurious practice is to keep them, especially if grown in fibre in fancy bowls, in too dry an atmosphere, in gas-lighted rooms or near the stove, they like nothing better than being stood out in a fine rain, but care must be taken not to leave them out if frost is likely, as the water collected between the leaves, if frozen, will cause the spike to be thrown out.

The growing of hyacinths in glasses seems likely to become popular again, and very interesting is the method, showing the development of roots, foliage and flowers. October is quite early enough to set them, as at this time the roots at the base of the bulbs are eager to make away, which they certainly do if kept in the dark for a few weeks. Do not allow the bulb to touch the water, which should be changed occasionally.

When the bulbs are placed in the dark they should be looked over at regular intervals to see how root-growth is developing, and immediately there is about an inch or so of stem growth they should be transferred to a position outside where they receive a half light. After two or three days they can be given a position in a sunny window.



A BED OR BORDER OF HYACINTHS ALWAYS LOOKS MOST EFFECTIVE. *It can be suitably edged with other spring flowers like forget-me-nots.*

MODERN FREESIAS & HOW TO GROW THEM

IT will soon be time to prepare for freesias, and it is certainly time that they were ordered. The best time to pot them is August, and they can be potted safely until November, possibly December, but I have never tried this, because the results could never compare with those potted in August. As the coloured varieties are later in ripening than the common white, which is imported chiefly from abroad from a warmer and earlier climate, it is generally about the middle of August before they are available. I am writing this article as a freesia grower with a good deal of experience, and I am absolutely convinced that thorough ripening of the corms is essential if good flowering results are desired. It is, therefore, quite useless to hasten the harvesting and ripening process merely to satisfy customers with early delivery. It may satisfy them at the start to send the corms on August 1st, but, if not properly ripened, they will not be satisfied at the end with the flowering results. If, therefore, the corms are potted from mid-August to mid-September, there will be nothing of which to complain.

In our uncertain climate ripening of the corms is often a long job; possibly a difficult one, and, in spite of a great shortage of rain in my district up to the end of June, which would lead one to expect an above the average amount of fine sunny weather, yet it appears to me that this year freesias are later than usual, especially those planted out in beds in the house.

As soon as the corms are received they should be potted. I prefer to use 2 parts good loam, 1 part rough sandy top spit, and almost 2 parts of coarse silver sand. A small quantity of fine bone-meal is added but no manure.

Use well crocked clean pots of "Long Tom" type. Six corms to a 5in. pot is a good figure to work on. I prefer the "Long Toms" on account of their extra depth, which allows the big fleshy contractile roots more room than the ordinary pots. After potting the corms, which should be just below the surface, the pots should be stood under cover either of a cold greenhouse or a cold frame and given plenty of air. On no account cover the pots with any material, such as ashes or fibre. Goodness only knows why it has been done to freesias or, for that matter, any bulbs. Why cover them with an additional wet, cold blanket, giving the wretched bulbs hard labour to push up through to air and light? It seems to me all wrong. Anyhow, give your freesias full air and light, and sufficient water to create root action and maintain it, but no more. The growth will be strong and healthy from the start. If you are not convinced try the old method—plunge the pots under ashes, let the rain and/or the water-can do its worst or best out of control, let the corms expend part of their energy pushing up through that black blanket, and finally release them—showing them to have provided you with a few inches of weak, white, straggly growth instead of the sturdy green growth of those under cover of the house and under control of rain and/or the water-can. So much for that.

Freesias, being very nearly hardy, require but little heat, and the best results are obtained by growing them as cool as possible with very little more heat than is necessary to keep out frost. The cooler and slower the treatment the better the results—better flowers, better colours, better stems. I find this is far the best way, hence my exhibits at Vincent Square are seldom seen until the end of March.

Water should be given sparingly until there are sufficient roots and growth to require and absorb more. If insufficient water is given at the start, there is a possibility that growth may not start at all and the corms will remain dormant the whole season. This behaviour sometimes occurs from this cause, but not often; but when it does occur it is usually the result of insufficient or improper ripening. But the corms do not die. They form a new one on top of the old one. I wonder whether, in their native land, they get severe droughts—when there is insufficient moisture to create root or leaf growth that Nature has provided this method of reproduction to prevent the total loss of the species. The flower spikes will begin to show early in February, but before this some means of support will have to be

A FINE DISPLAY OF COLOURED FREESIAS AND THE FEATHERY PRIMULA MALACOIDES IN A SMALL GREENHOUSE.

Digitized by Google

given—not because the growth is weak, but because it is not sufficiently stout to withstand the laws of gravity when it gets to a certain height. There is nothing better to use than Allwood's carnation wire rings. The smallest size can be used for 5in. pots—and I hope to get the firm to make a smaller size than this. They last for years, and are easily adjusted and inconspicuous and in every way satisfactory.

When the flower spikes appear, liquid cow manure in diluted doses can be given, changing the diet with soot water or some fertiliser, such as Clay's. The feeding should be carried on after the flowers are over and when the foliage begins to turn yellow; gradually reduce the watering down to none at all. Then let the pots gradually dry out, and give them full sun warmth and absolutely dry treatment to ripen them off thoroughly. In ripening off my stocks the temperature of the house goes up to 120° Fahr., and this, with slight air on in the middle of the day to prevent it becoming too hot, goes on for three or four weeks before harvesting begins.

My advice is: If you cannot grow and ripen the corms properly, leave them alone and buy a fresh batch each year, for, unless treated properly, they will give nothing but dissatisfaction.

The flowers last well when cut, but you cannot cut flower and foliage and expect to get first-class corms the following season. Great care should be taken in cutting to leave sufficient growth on the plant to enable it to finish its work.

And now as to varieties. There were freesia trials at Wisley this year, and the awards were recently published, and these may be of assistance in selecting the varieties. I recommend the following, none of which is expensive:

Yellows. — Apogee, Buttercup, Golden King and Treasure.

Mauves. — Bluebeard and La Frappante.

Pink Shades. — Apotheose, Conquest, Jubilee and Mouette.

But a descriptive price list will tell you all about them.

I cannot recommend freesias for growing in bowls in fibre. I do not think the fibre is what they like, and the only results I have had have been failures. Also, they do not seem to like the atmosphere and conditions in which hyacinths, daffodils, etc., will succeed. If freesias are grown in a cold frame care should be taken that they have sufficient head room and that, in frosty weather, they get sufficient covering to prevent damage.

They can be planted out in a bed in a cold house or frame, provided ample drainage is given and sufficient water only and no more. Personally, I find they succeed best when grown thus, as the roots get a deeper and freer run than when grown in pots, and, the drainage being all it should be, they never get troubled by wet, cold and sour soil.

Colours are being improved every year, and many of the older sorts have long been discarded; but as yet these new varieties are expensive, and the beginner will, no doubt, be content to start with older and cheaper sorts. Let him—or her—make up his or her mind to start now and order some for the coming season.

G. H. DALRYMPLE.

ONE OF THE BEST OF THE PINK VARIETIES, FREESIA APOTHEOSE.

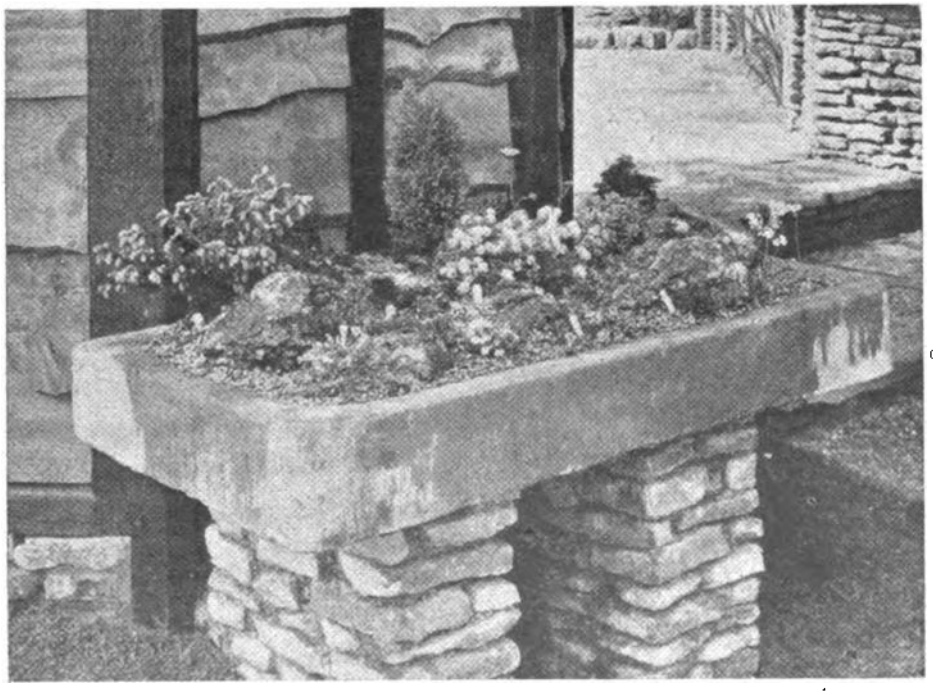
A NOVEL ROCK GARDEN

Alpine gardening in sinks is a vogue that is certain to increase in popularity. It can be accomplished in small space and at a minimum of expense.

WE often hear the words "Not anything is wasted," and although it is a scientifically proven fact, nevertheone might be forgiven for not realising that an old disused stone sink can be turned into a thing of beauty and a joy for ever, for within its comparatively small area can be constructed a charming little garden with miniature rocks, trees, shrubs and brilliantly coloured choice alpine plants.

While these miniature moraine gardens may be purchased complete with the plants well established, it is possible that some readers would like actually to construct a miniature garden themselves.

The first thing to do is to look around for a suitable sink, which should be as deep as possible to admit of a good depth of soil. The sink having been procured, no attempt should be made to clean or improve the outside portions of it—these should be left in as rough and weathered a condition as possible. The inside, in which the soil is to be placed, should be well scoured and thoroughly washed out with soap, soda and water. The drainage hole must not be stopped up, but covered with broken crocks; in fact, the base of the sink should have a thin layer of broken crocks or coarse ashes. Upon this should be arranged, in as natural a position as possible, the selected rock stone, which may be either a grey waterworn limestone or a yellow sandstone, depending upon the class of plants with which it is intended to furnish the sink. Having fixed the position of the rocks, forming suitable pockets for planting, the sink should then be filled with a compost composed of rich loam, coarse sand, leaf-soil, with a small proportion of charcoal nuts and limestone chippings, and possibly peat. Individual pockets may be provided, where the compost might be principally peat for any peat-loving subjects. Here the charcoal may be mixed, but the limestone must be omitted. Care must be taken to work the soil between and around the rocks to keep them in position, and the compost should be pressed or rammed hard to form a suitable planting bed. Alpines, in common with nearly all plants, cannot be planted too firmly, providing the compost has been properly prepared and is of a porous nature.



A SMALL SINK GARDEN PLANTED WITH ALPINES TO FORM A MINIATURE ROCKERY.

The planting may now be undertaken. The range of plants suitable for such a garden is certainly too numerous to mention, but later on we note a few that occur to us as being eminently suitable for the purpose. When planting it is desirable to have in mind the position which the sink is to occupy. Should this be a sheltered position with full exposure to the sun, sun-loving plants which thrive in dry positions should be chosen. If the sink is to be placed in an exposed position open to the four winds of heaven, only the hardiest of alpines are indicated. Where the sink is to stand in partial shade, primulas and other shade-loving plants and also some plants which thrive in peat will form the best selection. At least one or two choice dwarf conifers

Digitized by Google

should be used, such as Cupressus obtusa nana, and in no case should Juniperus hybernica compressa be omitted.

The choice of plants for the body of the sink is large and varied. An attempt should be made to select the small-growing varieties with the idea of getting in as many plants as possible flowering at different periods for the purpose of obtaining a show of bloom from early spring to late autumn. Naturally, the following at once suggest themselves: Primulas, saxifrages, alpine phlox, lithospermum, gentiana, alpine campanula, dianthus and androsace. In the early spring quite a gay fulfilment is secured by including small bulbous subjects, such as scilla, chinodoxa, Muscari azureum, Narcissus minimus and one or two varieties of the hardy cyclamen.

The planting being completed, an enhanced appearance is obtained by dressing the soil between the plants with a thin coating of limestone or granite chippings. A word of caution may be given here. It is advisable, when the sink garden is first introduced, that four sticks should be inserted at each corner in an upright position and one in the centre, from which should be threaded cotton for the purpose of preventing the too inquisitive birds alighting thereon and destroying the blooms.

While there is no doubt a beautiful effect is obtained by planting the sink with many different varieties of plants, equally successful results are obtained if the planting is confined to one class of plants alone, for instance, a long period of bloom can be obtained if the sink is planted with primulas only, with, say, three conifers to enhance the broken-up effect provided by the rocks. In this collection should not be omitted the following: Wanda, Juliæ, marginata, rosea, farinosa (Craven Gem), Linda Pope and The Jewel. Again, another beautiful result might be obtained by employing only campanulas. With these it is possible to provide bloom for even a longer period of time than is the case with primulas, because the majority of the latter are early-flowering subjects. Among the campanulas the following might be used for the front, having a pendulous habit: Istriaca, muralis major, pusilla Miss Willmott, and for the body of the sink the following new varieties should not be overlooked: Bellardii Miranda, garganica W. H. Paine, and Lauri, which came from the Greek Islands and throws a beautiful shade of lavender blue bells.

As regards sinks of saxifrages, it is not advisable to mix the mossy varieties with the kabschia. One sink should be devoted to the mossy and one to the kabschia, but two or three of the encrusted varieties might be employed in both of the other sections for the purpose of giving height. Among the most useful encrusted varieties are longifolia, lingulata Albertii and Cotyledon Caterhamensis. Among the mossy varieties Aldenham Pink Queen of the Belgians, Apple Blossom and Wenlock Peach should not be omitted. Among the kabschia section Borisii, Irvingii, Myra and Jenkinsæ should not be omitted.

A sink garden should stand 2ft. to 2ft. 6ins. above ground level. There are innumerable positions in most gardens where one may be placed with advantage. In formal sunk gardens recesses are generally provided either for seats or ornaments. Such a recess is quite a suitable position. A sink placed on each side of the entrance door to a house produces a nice effect. The illustration portrays one of two garden sinks which stood on pedestals at the back of a Tudor garden house which formed the viewpoint of the formal garden exhibited by Messrs. William Wood and Son, Limited, of Taplow, at the recent Chelsea Show. It will be observed that the sink stood on one side of the entrance to the formal garden and suitably balanced the stone wall on the other side of the entrance. In addition to balancing the retaining wall, the sink tended to break the rather austere lines of the Tudor garden house which backed on to the public pathway. The possibilities of improving a small town garden are greatly increased by the use of a stone sink garden, for it can be arranged to provide an interest and charm usually furnished by a rock garden.

A PLANT FOR A SUNNY SITUATION

THE Peruvian lilies (alstrœmerias) are worthy of much more general cultivation than they receive, for these plants are very distinctive and beautiful. Of course, some of the species of alstrœmeria are not hardy, and others require some protection during the winter; but there are several kinds, and quite a number of hybrid forms which, with reasonable conditions, will grow almost anywhere in England. The best place for the culture of alstrœmerias is a south border or along the front of a wall having a warm aspect where, if the soil is not light and dry, it should be brought into that condition. If the ground inclines to be heavy, the position should be prepared at the outset. Dig out the ground to the depth of 3ft. and spread 6ins. or so of brick rubbish over the bottom of the border. Shake over the drainage a layer of dead leaves or half rotten manure to prevent the soil from working through the cracks and so preventing the passage of water. The soil which is finally added to make up the border should have sand and road grit added to it if this seems needful. The plants must be set about a foot apart, and in cold districts it is well to have the roots from 6ins. to 9ins. deep, so that they may be protected from frost.

Alstrœmerias may be propagated by means of root division, but this is not always a very successful method. Established plants greatly dislike being disturbed, and a very satisfactory way of increasing the stock is by means of seed. These can be sown when ripe, or in the spring, in pots or boxes and kept under glass. When the plants are about 2ins. high they should be moved to a fresh box or pot and finally placed in their permanent quarters. If the seeds are sown out of doors in the spring, or after ripening in the late autumn, the results are often extremely good. Cover with from 2ins. to 3ins. of soil where the plants are to remain, and put three or four seeds in a patch so as to make sure of getting at least one fine plant. With good treatment plants raised in this way will begin to flower when they are a year old. Alstrœmerias will give a much longer display of bloom if, during dry weather, they are watered. Remove the dead flowers, as seed setting is on a very profuse scale and it will tend to exhaust the plants and render them less free flowering in the following season. The stems of alstrœmerias should never be cut down, and it is always better to allow these to die away naturally.

A. aurantiaca is the most vigorous growing kind, which sends its stems to the height of from 2ft. to 4ft. The orange red blooms (which vary a good deal in different localities) are borne during the summer and autumn. This species is such a free grower that it is easily naturalised in loose sandy soils, or even those of a heavier nature, which have been thrown up into banks. The plant is a most useful one for placing in association with shrubs and trees where the situation is not heavily shaded. Here the clumps will remain for years and require very little attention. A. chiliensis is a hardy species of great beauty which is also very variable; the flowers ranging from a rose colour through red to an orange shade. A. Ligtu and A. pelegrina are both beautiful, but they are somewhat tender. In many localities these thrive out of doors, especially if the roots are protected with fern or similar material during the winter. A. pulchella is a very distinct plant with crimson-purple blooms that are not quite so brilliant as the other kinds named. Most of the hybrid forms of alstrœmeria are worth growing, and an exceptionally fine one is A. Errembaultii, which has flowers most curiously tinted with crimson, yellow, and white. L. B.

ALSTRŒMERIAS SUCCEED WELL IN A WARM DRY BORDER IN FRONT OF A WALL.

THE BUSY MAN'S PAGE

August Reminders.

CARNATIONS may be layered during the early part of the month.

Dahlias should be tied up where needful, and if unnecessary shoots are pinched out the production of flowers will be greater.

Plants like dahlias, chrysanthemums, gladioli, herbaceous phloxes, hollyhocks and cannas will greatly benefit if they are given liquid fertiliser once or twice a week.

Many herbaceous plants which have gone out of flower will blossom again if cut back rather severely.

Remove all faded flowers from annuals to prevent seed setting, which will soon bring the production of blossoms to an end. Cinerarias, Chinese primulas, etc., grown in cool frames must be kept protected from strong sunshine.

Seedling auriculas, pansies, polyanthuses, etc., may be transplanted to about 6in. apart.

Cuttings of zonal pelargoniums may be inserted in pots or in the open ground.

Roses may be budded during the early part of the month.

New plantations of strawberries may be made.

The canes of raspberries that have fruited may be cut down to the ground and thin yearling shoots also cut out.

Fruit trees on walls or fences should have young wood tied in and all others not wanted cut out.

Finish planting out green crops for winter use and keep the hoe going between others that are growing to maturity.

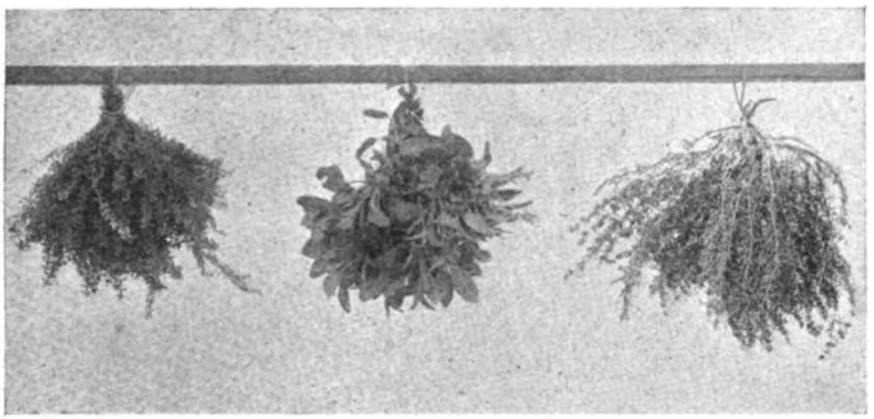
Second early potatoes will be fit to lift and the land occupied by them may be filled with cabbage crops, spinach, turnips, onions, radishes, carrots (early stump varieties), etc.

Early celery may be earthed up.

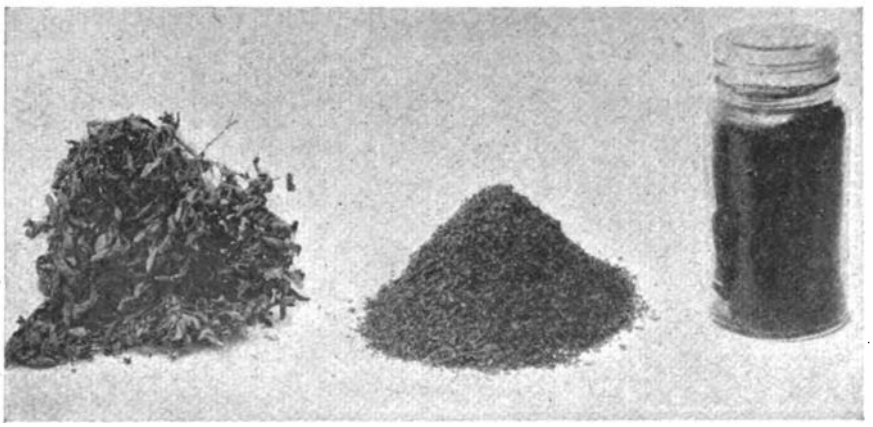
Lettuce for winter may be sown.

Drying Herbs.

IN most cases the early part of August is the best time for herb drying. Herbs should be gathered on a dry day, and when the leaves are free from dew. Tie the sprigs in small bunches, and then, for a few hours, hang these in a shady place where there is a draught of air. Then place the herbs on wire trays or large dishes in an oven where the heat is declining. Turn the bunches about repeatedly, and, when the foliage is crisp, the drying process is complete. The dried herbs may be enclosed in brown paper bags which are suspended in some suitable situation. A better way is to work the leaves from the stalks and then place these in well stoppered bottles. The bottles should be kept away from strong light, which tends to affect the flavour of the herbs.



THE METHOD OF DRYING HERBS.
The sprigs should be tied in small bunches.



WHEN DRY, THE LEAVES SHOULD BE RUBBED THROUGH A FINE SIEVE AND STORED IN AIRTIGHT BOTTLES.

New Lawns from Grass Seed.

YOUNG grass, raised from seeds sown in August, is always more likely to make a good lawn the following year if it successfully passes through the winter, than the young grasses resultant from seeds sown in spring, when a dry spell of weather follows. Of course, it is not always convenient to sow grass seeds in August, but where it is much valuable time is saved. Where it is absolutely necessary to dig deeply to remove the roots of weeds, or where it is necessary to fill up with new soil and there must be time allowed for it to settle down, such work should be done as soon as possible, but the actual sowing should be deferred until the following spring. If the ground is fairly level and the soil clean—free from the roots of tap-rooted weeds, convolvulus and couch-grass, then it is inadvisable to dig deeply. Simply loosen the surface portion, break up the largest lumps, make the surface level and the soil fine, firm it thoroughly and it will be in a suitable state for sowing. If it is convenient to do so, sow the seeds on a calm day, first mark out the plot to be sown into squares, 3ft. by 3ft., then it will be much easier to sow the seeds evenly. If the soil is rather dry it will not adhere to the roller when the latter is passed several times over the sown ground. Very small grounds may be beaten with a clean spade instead of being rolled. If rain follows immediately, the seeds will soon germinate.

How to Raise and Grow Mignonette for Winter Flowering.

JUST now and during the month seeds of the best strains of mignonette should be sown. The plants, when grown under glass, are liable to become drawn and straggly, and the inferior strains are the worst offenders in this respect. The naturally dwarf, compact-growing varieties are the best, and, with ordinary care, very fine specimens can be grown and flowered in 6in. pots. As the seedlings do not transplant satisfactorily, they should be sown in small pots and, in due course, re-potted, or sown direct into 6in. pots and duly thinned out to one, two or three plants, as the case may be. If one plant is flowered in a 6in. pot, the spikes are very large; if more plants in a pot there are more spikes, but the latter are smaller. Be sure that the loam is quite free from wireworms. The loam should be from a heap cut and stacked about six months ago, so that all the grass roots will have perished. A small proportion of sweet leaf-soil will be beneficial, and a small quantity of the compost should contain a sprinkling of bone-meal, to be placed in the bottom of each pot, the bulk of the compost, without the bone-meal, being placed on the top and the seeds sown in the latter. Drop the seeds thinly near the centre of the pot and cover lightly. A cold frame will be an ideal place for the pots and the resultant seedlings. Thin out the young plants at an early stage of growth; pot on from smaller pots when the latter are becoming filled with roots. In every case be sure that clean pots and crocks are used. Expose the plants to full air conditions when the weather is fine. Stop the plants when they are 3ins. high, early in October. Winter the plants, if convenient, on shelves in the greenhouse and begin to feed them early in February. Bismarck, Machet and La Triumphant are good sorts.

Gardening Soaps.

SOAP is used for many purposes in the garden, such as the washing of greenhouses, frames, tools, etc. Then soft soap enters into the composition of certain mixtures employed to kill pests. In all cases it will be found that disinfectant soaps are much better than the ordinary kinds. These are no more expensive, and with them it is possible to form penetrating insecticides which will work their way into cracks and crevices and destroy lurking pests. Lifebuoy or carbolic soap, and Izal disinfectant soap, in both the hard and soft forms, are excellent.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Chrysanthemum Culture.

THE chrysanthemum grows in popularity each season, chiefly, no doubt, because of its value as a cut flower. The enthusiast who wishes to grow specially fine single blooms should just now give a little more attention than usual. For large flowers, the side buds must be rubbed off as soon as they appear. Those who, like myself, prefer a natural spray of rather smaller flowers, will have to stake and tie the shoots carefully to prevent breakage by winds. In staking, always allow each shoot plenty of room for the sun and air to reach the leaves. A little fertiliser sprinkled on the soil round the plants will make healthy foliage and help to resist the leaf miner.

Sweet Violets.

MANY gardeners have an empty cold frame at this season, which they will not be needing until seed sowing time next year. This could be used with advantage for growing violets, which grow more freely when protected in this way. Plant the roots as soon as they are received, 15ins. apart each way. A rich soil is needed, and the bed should be made up to within 9ins. of the glass. Decayed leaves should be removed as soon as noticed. Ventilate the frame freely except in the most severe weather and give only a very little water during the winter. Princess of Wales is a deep blue, long-stemmed variety, which would repay a little extra care of this sort. There are also violets of a reddish shade which are extremely attractive and add variety to the collection.

A Prize Garden.

ONE of the gardens which was awarded a first prize in the local Garden Competition, organised by the Gardens Guild in Acton this season is shown here. All the trellis work, arches, etc., were home made, and the plants grown by an amateur. Such a picture shows how much can be achieved in a limited space by exercising a little ingenuity. The arches add variety to the garden and make it appear larger than it would otherwise do, besides forming ideal supports for climbing roses and other plants.

Plants in pots find a home on the shelves which stand against the walls. The advantage of growing a few extra pots of flowers is two-fold. Failures in the garden, or gaps that appear from time to time as plants die off, can be filled up with plants that are almost in bloom. In addition, a supply of room plants can be maintained, the plants being changed often so that all of them get the advantage of a period in the open air.

A PRIZE WINNING GARDEN.

"None So Pretty."

THE oldest saxifrage in our gardens is familiar to all by its cloud of pink flowers, which appear in June, and its rosettes of spoon-shaped leaves, which make a charming edge to a border or rockery, remaining green throughout the year. Saxifraga umbrosa is the botanists' name for it, but it is known variously as Pretty Betsy, London Pride and None So Pretty. It is sometimes thought that the name London Pride was given to it on account of its suitability for London gardens, but actually it derived the name from London, of Messrs. London and Wise, the florists, who first put it on the market. It thrives everywhere, but seems most at home as an edging to a rockery or border. To get fine sprays of blossom and healthy foliage, divide the plants now. Cut with a trowel into pieces with three or four heads to each and replant where it is desired to flower.

Cuttings from Summer Flowers.

A NUMBER of the flowering plants which are making such a brave show in our gardens now can easily be increased by cuttings. Pentstemons, whose stately flowers are well able to withstand the air of towns, make plenty of side shoots suitable for cuttings. Short-jointed branches, not very sappy, are the best to select. They root easily in boxes or pots of soil. If possible they should be kept close for a week or two, and where a cold frame is not available, a deep box and sheets of glass will do. As soon as the cuttings have rooted, give them all the air possible, removing all coverings until the frosts arrive. Geraniums, fuchsias, heliotropes, snapdragons, in fact most of the perennial plants can be increased by cuttings taken at this season. But if you have no means of protecting the young plants from frosts, then propagate only the hardy plants which do not need wintering under glass.

Lambs' Ears.

CERTAIN plants seem to have claimed the old-fashioned cottage garden for their home. Such a one is Stachys lanata, called Lambs' Ears, from the grey woolly appearance of the leaves. This plant will soon establish in a garden and needs very little attention. The striped flowers are useful for cutting, and when placed in water, go on producing flowers after the habit of forget-me-nots.

A Good Shrub.

A NOTED authority on shrubs says of the Spiræa ariæfolia (discolor), which is here illustrated, that "in any selection of spiræas this must be placed in the best half dozen." Those who know its masses of creamy white flowers which grace many a shrubbery at this season will certainly agree. It is a handsome shrub, generally 8ft. to 12ft. high, but sometimes much more, and it is seen to the best advantage if planted against a background of dark green. It must, however, receive a full amount of sunlight for the best results.

A DECORATIVE SPIRÆA, S. ARIÆFOLIA.

Layering Shrubs.

THERE are many plants which are increased most easily by pegging down the ends of long side shoots. Loganberries and blackberries are notorious for the way in which they root themselves if the shoots are allowed to reach the ground instead of being tied to supports. To increase the stock of these and also of many flowering shrubs which have long stems, cover the stem with soil about a foot from the tip. A slit should first be made lengthwise, so as partly to sever the stem. The free end of the shoot can be staked obliquely to keep it in position. Roots will quickly form, and the new plant can be then severed from the parent and transplanted. The two essential things about layering shrubs are a constant state of moisture and the fixity of the part to be layered.

Woolly Aphis on Fruit Trees.

MANY amateurs are surprised to learn that the small patches of a substance resembling cotton wool which are sometimes found on fruit trees at this season are actually a kind of aphis. At times this pest is found in large quantities, and it is then necessary to spray the trees with a good nicotine wash, using a strong spray. If, however, there are only a few patches to deal with, they may be painted with methylated spirit, which will destroy the insect.

This pest attacks the roots in just the same way that it attacks the tops of the trees, and is, of course, much more difficult to eradicate if it has taken possession underground. Carbon bisulphide is used to destroy it in this case, but the treatment must be delayed until autumn or winter.

WORK IN THE FLOWER GARDEN

Foam Flowers for Border or Rockery.

THE tiarellas, or foam-flowers, belong to that useful class of plant which might be termed general purpose subjects, for they are adaptable for the rock garden, the border edging, woodland and wall gardening. They are indestructibly hardy, easy to grow in sun or shade, and they—more especially T. cordifolia—are attractive from early spring to late autumn. All the foam-flowers are of North American origin, and the species named is the best-known and most useful for the rock garden. It is a low-growing plant with pale green, five-lobed leaves which assume vivid autumn tints. Spreading by means of runners like a strawberry, it loves to thread its way between the rocks whose chinks it will quickly embroider with its pretty foliage and fluffy spikes of white flowers in May or June, these standing at about 6ins. There is nothing more simple to grow under such conditions, and to increase the plant one has only to detach the rooted runners. This can be done at any season, but preferably in late summer.

T. unifoliata is a more uncommon species, but there is no reason whatsoever why it should not be more generally grown. It differs from the foregoing in not making any runners, confining itself to a self-contained, compact clump. Also, it is much larger in all its parts, its handsome vine-like leaves are a deeper green with a touch of bronze, and the bold, erect flower spikes, which rise to 18–24ins., terminate in inflorescences which are creamy white with a rosy flush. This is a plant for the border rather than the rock chink or wall, since it enjoys a good fat loam and generous cultivation. As it makes no runners, T. unifoliata is not so readily propagated as the common foam-flower, but I find that if offsets are detached in summer or autumn, they will take root if potted up in leaf-mould, sand and loam, and placed in a closed frame.—A. T. J.

Sowing Violas and Pansies for Spring Flowering.

These Can be Sown Now in an Open Border.

WHEN distinct named varieties are grown the stock must be raised by inserting cuttings. Plants resulting from seed bear flowers of various colours, and many of the individual blooms are very large and extremely beautiful. If the seeds are of some choice strain it would be a wise plan to sow them in a cold frame or in boxes which can be covered with glass. But there must not be any undue coddling, as the plants have to withstand the winter prior to their flowering stage, as the few flowers often borne on strong seedlings during the autumn are not to be regarded as constituting the flowering period and all flower buds forming then must be pinched off. For general use the seeds may be sown in an open border, preferably in one on the north side of a wall or fence. The ordinary garden soil should be dug and cleaned first; then procure some rich loam, 2 parts, leaf-soil 1 part, and well rotted old manure—spent mushroom-bed manure for preference—1 part. Mix these ingredients well, but do not add any sand. This compost should form the seed bed and be about 4ins. deep. Sow the seeds very thinly, as the seedlings possess large spreading leaves, each seedling up to the stage of transplanting requiring nearly a square inch in which to grow. Much is gained by sowing the seeds thinly. Cover the seeds about ½in. deep with soil similar to that of the compost, except the manure—it should not contain any manure. Earthworms sometimes cause damage by heaving up small hillocks of soil and loosening the seedlings as well. An effective preventive is the watering of the original border soil with strong, clear lime-water about ten days prior to the date of sowing. The worms will come to the surface and should be picked up. The nursery bed should be treated in a similar way with the lime-water, as it is advisable to transplant the seedlings once in such beds before finally planting them in their flowering quarters.—GEO. GARNER.

Growing Bulbs in Fibre.

EVEN if memory has failed to remind us that bulb planting time is already here, the attractive displays of fancy "bulb bowls" in every china shop recalls the artistic effect possible within the living rooms, of certain bulbs grown in fibre. In the choice of bowls we would not dare to advise our readers (is not this essentially a ladies' department of gardening?), but we name a few of the easiest bulbs to grow: Roman and miniature hyacinths, the ordinary and "many-spiked" hyacinths, the early Dutch tulips, daffodils of all kinds, crocuses, grape hyacinths, some of the fritillarias and the dog's-tooth violets. Avoid irises, anemones and freesias, as these are not always satisfactory. The bowls and the bulbs having been obtained—and we strongly urge early purchase and immediate planting, the sooner the better—get sufficient prepared fibre from the seedsman and then pot the bulbs firmly in the fibre, previously placed in the bowl to within an inch of the top. Thereafter fill the bowl to the brim with water, allow to soak for an hour and then tilt, to drain away all superfluous water. Now place the bowl in a frame or in a box, cover finely sifted ashes to a depth of 6ins. and stand them fully exposed in the open for four or five weeks. Cover only from excessive rain or snow and throw a mat or old bag on top during frost. After this grow the bulbs on inside in a cool, non-forcing temperature. Town dwellers who cannot bury the bowls in ashes in the open, may put them in a dark cupboard, cool, for the same length of time, taking care to see that the fibre never dries up. Early planting, five weeks darkness and non-forcing give the finest results.

THE FEATHERY FOAM FLOWER (TIARELLA) LOOKS WELL PLANTED IN CLUMPS IN THE BORDER OR AS AN EDGING TO GARDEN STEPS AS IN THIS ILLUSTRATION.

The Present Treatment of Cyclamen.

SEEDLINGS which have been kept growing in cool quarters all summer are now ready to be potted up in their flowering pots, generally 5in. and 6in. sizes. The best compost is a coarse loam, containing a fifth of year-old manure or, when this is not obtainable, a sprinkling of hop manure or an ounce of bone meal per plant. Pot fairly firmly and keep the corm well above the compost. After repotting, water carefully, avoiding excess and yet taking care not to let the soil become too dry. Spray very lightly overhead in warm weather, using rain-water which has been standing in the sun. At this time old corms which have been resting may be shaken out of the old pots, repotted and treated in much the same way. Give plenty of light and air at all times, but shield from strong sunshine; damp down the ash bottom on which the pots stand in the frame, so as to keep the atmosphere round the plants moist. Towards the end of September, always erring on the side of earliness, take the plants inside; a check due to exposure to cold is a potent cause of flowers going blind; place them on the stage on an ash or gravel bed and begin to feed with weak liquid manure. See that all leaves and buds which damp off are at once removed.—LANARKSHIRE.

Transplanting Biennials.

OFTEN, failures with biennials may be traced to their not being transplanted at the proper time, and once again the quality of the seed is questioned when plants do not turn out right. At the present time, such plants as wallflowers, Canterbury bells, honesty, sweet williams are in seed-beds in many gardens. If they are left, it follows that they will have a struggle for existence, and in such circumstances the fittest does not always survive.

There is no skipping the duty of transplanting and planting out direct into their final quarters next October or November, thinking they will be just as good. If the best plants are wanted to stand the winter, there must, of necessity, be a shift from the seed to a nursery bed, and this should no longer be deferred, giving each plant 5ins. or 6ins. of space for growth, and so, when the time comes for getting them into their flowerming quarters, they will be sturdy specimens. One has only to mention Canterbury bells, which should be given all the room possible in their first shift, to demonstrate how futile it is to expect strong, healthy plants from an overcrowded bed. Transplanting time with biennials is important, and, if possible, the position for them should be an open one, away from trees.—W. L. L.

The Importance of Mulching.

IF flowers are being grown for exhibition, watering and mulching must be attended to if the weather becomes hot and dry. Roses never do so well as when mulched with littery manure. Copious doses of liquid manure are also beneficial, if given not too

Digitized by Google

strong, especially if the soil is at all dry. Where dahlias, gladioli, asters, carnations, etc., are meant to grace the show benches, mulching, watering and feeding with dilute liquid manure will help to swell the blooms and deepen their colour. Mulching is of especial benefit on light and sandy soils. When manure from cowhouse or stable cannot be got, cut grass, half-rotted leaves and similar material make a good substitute. Mulchings of peat moss litter, saturated with water and weak liquid manure, are beneficial among the flowers.

Cut straw, mixed with green herbage and thrown into a heap over which a few buckets of liquid manure are poured, will rapidly ferment and rot, and so produce a quantity of splendid mulching material. Poultry manure soaked in a tub of water, makes a good liquid to pour over the heap of straw. Urine and manure drainage of any sort are also of the greatest service in the production of mulching litter. Fibrous turves, when well decayed and saturated with liquid manure, after being chopped and torn to pieces, may also be used for mulching. Vegetable waste, including weedings, should be rotted and turned to similar use.—J. W.

Foxgloves and Ferns.

THESE combine to make a beautiful picture which at the present time is one of the chief attractions of the countryside. A pleasing feature may be introduced into the garden by growing ferns and foxgloves together, copying nature as nearly as possible in the matter of arrangement. A very suitable place is a semi-shady corner with a hedge or shrubs for a background, as, with such surroundings, the plants under notice harmonise perfectly and create a most impressive sight. Seeds of the foxglove should be sown at once. There are several beautiful strains in pleasing shades of colour, but a fair number of white and spotted kinds are very effective and, for the purpose indicated, are generally appreciated. If seed is sown in a partially shaded border, and the seedlings are thinned out to allow room for the proper development of those that remain, there should be good plants for removal to flowering quarters in autumn. Ferns are best planted in spring when they are about to make fresh growth. In the meantime, prepare the site by breaking up the ground well, taking care to remove every bit of root of any perennial weeds during the process of digging. Leaf-mould worked into the soil will add materially to the vigour of both foxgloves and ferns.—J. C.

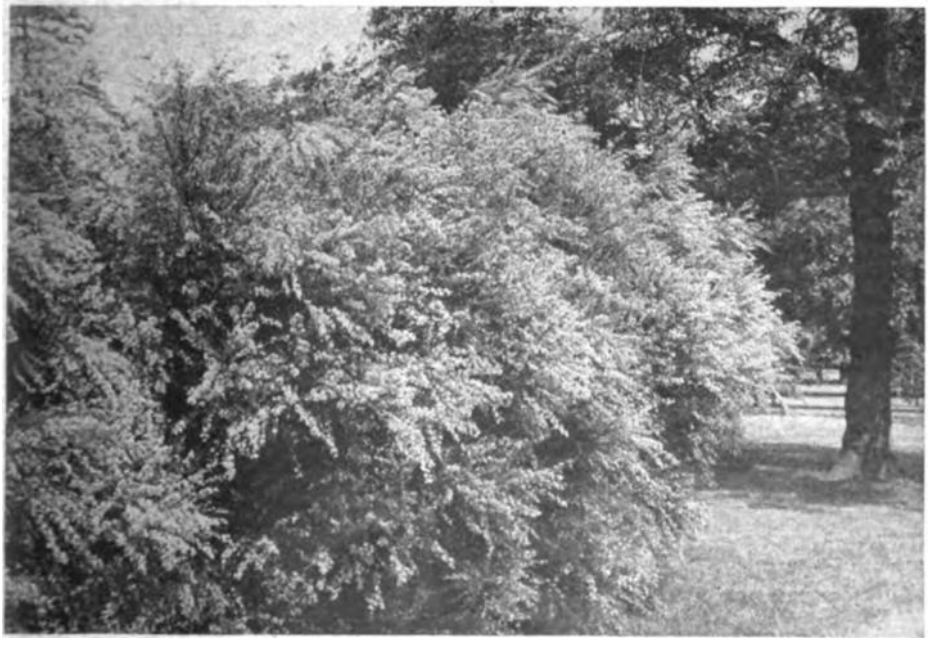
AN ATTRACTIVE EDGING OF LARGE-LEAVED MEGASEA SAXIFRAGES.

The Broad-Leaved Saxifrages.

THE race of saxifrages, or megaseas, with the large, elephant-ear leaves and white or pink flowers in spring, is so distinct that its members have been grouped in a genus of their own under the name of Bergenia. There are several species and varieties of these saxifrages—to use the more familiar term—and an exceedingly useful lot they are, for not only are the branching flower-heads large and attractive, but the foliage is very ornamental at all seasons. Moreover, they will prosper in almost any kind of soil or situation, they are practically pest-proof and seem to enjoy the longevity of an oak. Drip they do not mind; they thrive in the atmosphere of towns and are as easy to propagate by division as a clump of rhubarb. All are natives of high mountain ranges of Central Asia and Siberia.

S. crassifolia is a well known species with large trusses of rosy flowers standing well above the leaves in April or May. This is a first-rate kind for growing where a foliage effect is desired, for the leafage, handsome at all seasons, colours well in autumn. S. cordifolia is considered a form of the above, and it has even larger leaves. Of S. crassifolia there are many varieties offered in the lists, and some of these are singularly striking foliage plants, the leaves being richly tinted on their under sides with crimson or purple. From crossing S. cordifolia with the somewhat difficult S. purpurascens several excellent hybrids of proved garden value have also been raised.

An early bloomer and one not so reliably evergreen is the Himalayan S. ligulata. This is an excellent cool house plant, but it may often be seen doing well in the open when afforded a little overhead shelter—enough to secure its flowers from spring frosts. These blooms are very large, the trusses broad and generous, and varying in colour from white to a fresh rose pink. S. Stracheyi is a rather smaller plant than the foregoing, but when in bloom it is no less imposing, the white or creamy white, rose-tinted blossoms being yielded in bold clusters. These do not usually appear until April or even later, and they stand rough weather well. S. Stracheyi is undoubtedly one of the best flowering species of this section for outdoor culture, but I am told that S. Milesii—probably a form of S. Stracheyi—is even better and later.—A. T. J.



THE LATE FLOWERING GENISTA CINEREA, A HARDY AND DECORATIVE BROOM.

A Fine Late Flowering Broom.

DURING late May and June Genista cinerea forms one of the most arresting features among our hardy flowering shrubs. At this season it is particularly welcome, for the great majority of shrubs have by this time passed their best. It is of graceful appearance, growing up to 10ft. in height, with the branches disposed in a most pleasing and informal manner, and each branch absolutely wreathed with deep golden yellow pea-shaped flowers. The delightful fragrance, which is most noticeable during the morning and evening, forms an added attraction. Those who do not possess this desirable shrub should certainly make a note of it, and procure it for planting when the season arrives.—T. H. EVERETT.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

FOLLOWING on the unseasonable weather experienced this summer, there is general complaint regarding the backward condition of sweet peas. In some gardens the plants are only about 18ins. high, with thin wiry stems and shrivelled foliage. In other cases the plants have attained a height of 3ft. to 4ft. and, to all appearance, are strong and healthy and capable of throwing long stems and good blooms, yet up to the end of July have seldom produced blooms worth cutting. The buds which have appeared are mostly puny, discoloured specimens that stick up perpendicularly from the end of the stems, and in a few days drop to the ground at the slightest touch. It is only those buds that are to be found hanging in a cluster from the end of a graceful curve that will develop properly; consequently, these are the only buds which should be allowed to remain on the plants. It is a simple matter to differentiate between the two types, for if the stem does not assume a curved formation by the time it is 3ins. long it may be snipped off, so that the strength of the plant may be concentrated in supporting the good buds.

The cause of bud-dropping is a controversial subject. Among the various explanations which have been advanced are: faulty soil conditions, excessive moisture at the roots, over-strong and too early supplies of liquid or artificial manures, and a sudden drop in the temperature. In a season like the present when growth is slow, there is an undoubted tendency on the part of amateur growers to apply stimulants too early and too often. This is borne out by a letter received from the owner of a housing-scheme garden who has fed his plants several times with liquid manure and sulphate of ammonia and wonders why the flower buds are dropping. Sweet peas that are growing in well prepared soil that was trenched in winter should not require any stimulant except soot water until the plants begin to show signs of exhaustion. In Scottish gardens this stage is usually reached about the second or third week of August, when there is a preponderance of three blooms on shortening stems. In that event it is advisable to cut off the stems and commence feeding the plants once a week with a weak solution of liquid manure.

Some doubt seems to exist among a certain class of sweet pea growers as to the number of side shoots that should be allowed to remain on plants that are intended for ordinary garden purposes. As a general rule, a healthy plant can support two or three side shoots and be capable of producing flowers suitable for decoration. It should be understood, however, that any side shoot which is left on a main stem will in turn produce side shoots of its own, and this "second generation" of growths must, of course, be pinched out. In his Annual Supplement, Mr. Unwin shows the number of stems or growths to leave on each plant; but, while the figures are intended as a guide to the vigour of each variety, he suggests that the grower should use his own discretion in the matter.

While on the subject of sweet peas, I may mention that the Scottish National Society have decided to continue the trial of seedlings not in commerce in 1928. Raisers are invited to send twenty-five seeds of each variety to the secretary, Mr. John Smellie, Westwood Cottage, Helensburgh, not later than September 20th, as the last week of that month is the best time to sow in autumn in Scotland. After this year's experience, it is not surprising to find a request to raisers not to send any varieties except those which they consider properly fixed.

Among the yellow roses of the climbing Wichuraiana type, Emily Gray still reigns supreme. Coming into bloom in the early days of July, before the hybrid teas began to show colour, it has continued to flower freely and, at the time of writing, the bushes are conspicuous for the wealth of golden yellow buds, suggestive of a miniature Mme. Ravary. These good qualities, however, do not exhaust the charms of this truly wonderful variety. The profuse and pretty foliage is very glossy, possesses great substance and, besides being mildew-proof, is practically evergreen. It has been likened to Berberis vulgaris, and is almost worth growing for its foliage alone. There is no place in the garden but will be adorned by its presence, and, having proved its merits during the past three or four years, I can confidently recommend it for the clothing of pillar, arch, trellis or wall.

The dwarf hybrid tea roses are now at the height of their bloom, and, while several, favourites, such as Betty Uprichard, Diadem, Covent Garden, General Haig, John Russell, Sensation and Wilhelm Kordes, have, so far, been disappointing, others have been outstanding in respect of the size, form and colour. Those that have distinguished themselves in that respect and have qualified for places in the front rank are Maud Cuming (peach, coral pink and orange); Noblesse (apricot primrose, yellow with outer petals flushed pink), a most refined flower; Mrs. F. W. Vanderbilt (orange, shaded apricot); Mrs. C. E. Pearson (orange flushed red); Etoile de Hollande (the best dark red for the garden); Sunstar (salmon red, shaded yellow); and Shot Silk (cherry cerise overshot salmon orange). The last named pair are distinctive in their beautiful combination of colour, but possessing the defect of all these roses, their transient existence is accurately described in the expression "a bud in the morning and full blown by night." Among other good roses which have made a creditable display are Angele Pernet, June Boyd, Padre, Countess Clanwilliam, Mrs. Henry Morse, Courtney Page, Gwynne Carr, Una Wallace, Vesuvius (a grand free-flowering single rose), Asperant, Marcel Rouyer, Mrs. Fred Howard, Ophelia, Betty Hulton and Lady Inchiquin. Fragrance in a superlative degree is present in Angele Pernet, Etoile de Hollande and Shot Silk.

Reports have reached me from different parts of Scotland indicating a heavy mortality among roses. In a South Ayrshire garden the losses represent nearly 30 per cent. of the collection, and the strange thing is that the roses, in almost every case, began to die off in June when the bushes were in bud.

ST. MUNGO.

WHAT OUR READERS SAY

PEACH PEREGRINE.

SIR,—The accompanying illustration will give some idea what this delicious fruit is like; though, unfortunately, it does not show to the best advantage the handsome appearance of the fruit.

Peregrine is very juicy and of excellent flavour. The skin is soft and requires careful handling. As a fruit to be picked and placed on the table immediately it is all that can be desired.

Owing to its delicate skin it is not a first-class market variety. Unless it is carefully marketed the fruits soon bruise and deteriorate. Where peaches can be successfully grown outdoors in this country, I think Peregrine will hold its own. It forces well and is equally adapted to a cool house. It is a good grower and crops regularly and evenly.

A BASKET OF PEACHES, VARIETY PEREGRINE.

It is a good cropper and forces well in a cold house.

The tree from which the fruits in the illustration were picked was planted about six years ago, and this year it has a crop of about 120 peaches, the average weight of each fruit being 7oz.—P. E. CRICK.

SOLANUM CRISPUM.

SIR,—Your correspondent, "T. W.," in his interesting note on that attractive shrub, Solanum crispum, omits reference to the varietal form grown at Glasnevin. The

Digitized by Google

florescence of this latter appears to the writer to be far more abundant and lasting than the common garden form. Further, the blooms are a rather darker shade of purple.—C. J.

FISH IN A SMALL POOL.

SIR,—With reference to a letter signed "Rosyth," in your issue of THE GARDEN for July 9th, I should like to mention what we think happened to a small carp in a small pond in our garden. This carp had been living in our pond for quite a long time, when one summer morning we noticed a long and beautiful grass snake gliding about in the water and disappearing under some large stones, and, close by, the gruesome remains of a large half-devoured frog. Next morning the carp was discovered dead, a foot or two away on the grass, with a deep gash in the side of its neck. We inferred that the snake had pulled it out of the water, but found it impossible to eat it, or else had been disturbed and fled.—L. GREGORY, *Peaslake*.

GROWING PLANTS IN BARRELS.

SIR,—I was interested in "G. S. T.'s" article on the growing of plants in a barrel, as I have seen this principle used with great success.

In particular is it most useful in the growing of strawberries, which otherwise, through lack of space could not be grown at all.

A 54-gallon cask will take over a hundred strawberry plants, and this amount would fill a fair sized plot. As it is difficult to get water to reach the roots of the plants which are low down in the barrel, the following device is necessary.

Before filling up the barrel with earth, place upright in the centre a stove pipe or other metal tube of about 3ins. diameter and having holes of an inch size punched in it at intervals up its length. The pipe must be long enough to project a few inches above the earth when the barrel is full. Water poured in from above to fill the pipe will percolate through the soil to reach the roots of all the plants.

I wonder that this excellent system is not adopted by those having very small garden space.—GUY WUY, *Yoxford, Suffolk*.

LONG LIFE FOR CUT FLOWERS.

SIR,—In the article in THE GARDEN of July 23rd, "Long Life for Cut Flowers," by "B. D. S." it is said that "border lupins" seem to drop after two or three days in water. I suppose that perennial lupins are the ones meant. I grow these in large quantities and find that they last well for at least a week if put straight into warm water in which a crushed tablet of aspirin has been dissolved. I find that they do best in a large flat bowl which holds about 2½ gallons of water; in this I put two five-grain tablets of Howard's aspirin. The bowl holds about nine to ten heads standing upright in glass flower supports. They never seem to do as well in deep glasses. —K. HELY-HUTCHINSON, *Amersham*.

ALPINES IN SMALL GARDENS.

SIR,—Mr. Harris' photograph in the July 23rd issue shows what can be done by an enthusiast who goes to work on the right lines, but I have one criticism to make, and it is this: Why go to so much trouble to grow alyssum, arabis and aubrietia? His garden is at once too good and too small for such common rampant plants.

No doubt it is unfair to expect the more difficult alpines to flourish in London smoke, but many very beautiful things are quite easy to grow, and I do not think he need have any fear with the dianthi, Gentiana sino-ornata, Primula Juliæ and some of the violas, such as bosniaca and gracilis.

I would not have troubled you with another letter had I not so often noticed the mistake of growing plebeian plants when the fairy princesses of the rock garden are begging to be admitted.—G. FIELD-MARSHAM.

RECLAIMING AN OLD ORCHARD.

SIR,—Now that daffodil-planting time is coming round again, the following interesting experiment which I carried out may be of interest to your readers. This is part of a plot reclaimed from an old orchard three years ago, and planted with daffodils last autumn. The old turf was left for paths. Previously there was a hedge right next to the tennis court, but on digging the plot I found that part of it had been made up with clay dumped there from the tennis court foundation. I took up the hedge and used it to burn the clay. The site of the hedge has been planted with rambler roses and flowering shrubs. This photograph was taken in spring last year.—D. R. ACHESON, *Berkeley, Glos*.

DAFFODILS NATURALISED IN DRIFTS IN AN OLD ORCHARD

WINTER SALADS

Sowings of various crops can be made now to ensure a supply of these desirable saladings.

IN Paris, Brussels and all the large cities of Europe the salad plays an important part in the daily menu. Throughout the winter one is served with just as excellent a salad as in the summer, only of a different plant. These winter salads generally consist of blanched crisp golden yellow endive, both the curled or broad leaved, often called *scarole*; then there is the deep green salad known as corn salad or lamb's lettuce, again the chicory (Barbe de Capucin) and the blanched dandelion.

Now, all these salads are perfectly easy to grow in England. All gardeners should be able to keep up a supply of lettuce out of doors in the shape of Sutton's Winter White Cos, until the end of November, simply by sowing seed now in lines and then thinning out. (By sowing in late August and September in the same manner, and pricking out in January and February, if mild weather, these lettuces are ready for eating early in May.) The Sutton's winter lettuce-leaved Batavian endive and curled endive should be sown now in lines, and again at the end of August, thinned out after three or four weeks to 18ins. apart, as they grow into enormous plants by the third week in September. You can on a dry day start to tie up the top of some of these plants to blanch, leaving plenty of room for the centre to swell. Every week continue to tie up more, so that there is a continuous supply. Another good way is to transplant young plants into a broad trench 1ft. deep and 18ins. to 2ft. wide; in this way they get some shelter and in very frosty weather old pea sticks can be placed over the trench, and mats thrown over them.

Corn salad or lamb's lettuce is comparatively unknown in this country. It is of very quick growth and as easy to grow as a weed, and not at all particular as to soil; but it does best of all if sown in an open, dry situation. You can either sow broadcast or in drills 6ins. apart, and thin out to 4ins. between each plant. If a succession is required through the winter, sow the first lot in the middle of August and then fortnightly until the end of September. The plants, which form bright green little rosettes of leaves, can be cut when they have formed half a dozen leaves, or allowed to grow larger; the simplest way is to pull the whole plant up and cut off its roots. American or land cress, which has the same flavour as watercress, can be grown in the same manner, only in shady spots such as under currant bushes, etc., and only the tops of the leaves used.

Chicory should be sown in rich deep soil (not lately manured) in May and June, in rows 1ft. apart, and the plants later thinned out to 8ins. or 9ins. In autumn the roots must be carefully lifted, the tops cut off just above the crown, and then the former packed into deep boxes or pots, with moist light soil or leaf-mould between them. They then should be placed in a cellar or shed where the temperature is well above freezing point, in complete darkness. It is possible to start cutting in three weeks or a month from the time of planting, and a good supply should be kept up from November to May.

For dandelion salads the seeds should be sown in May or June on dry ground, the plants thinned out to a foot apart each way, and any time in the autumn or winter the roots should be lifted and treated in the same way as chicory, or in the spring the plants can be blanched out in the garden by placing boxes over them.

If the above salads are grown, with a good collection of cos and cabbage lettuce during the summer months, there should not be a day in the year when the household has to go without a green salad. Additions to salads can be made with the following: celeriac, celery, chervil, chives, hearts of spring cabbage, nasturtium leaves, radish, sorrel, tomato and watercress. Mustard and cress is beloved by some but is really a very weedy, stringy plant. EVELYN VENNING.

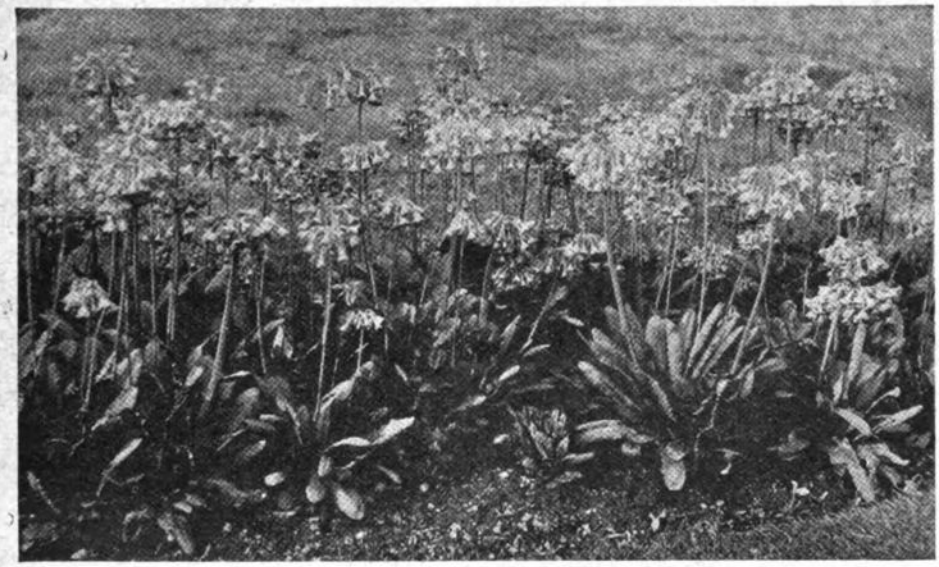
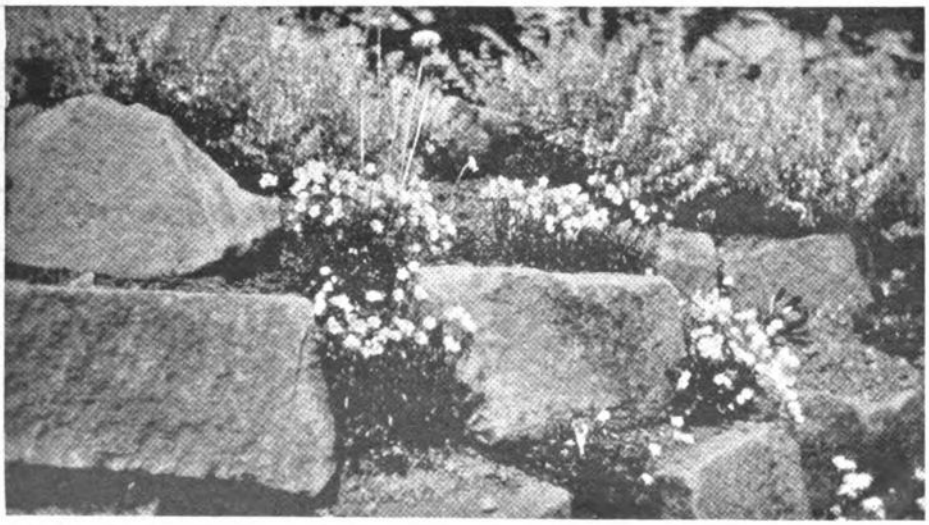
OUR PHOTOGRAPHIC COMPETITION

A pergola can be made one of the most attractive features in a garden if it is suitably placed and clothed with appropriate plants. In this illustration an oak seat backed with split oak fencing is placed at the end of the pergola, which is itself made of split oak tree trunks and covered with Wistaria multijuga, honeysuckle, clematis, Rose Evangeline, François Juranville, Emily Gray and others. On each side of the 4ft. path are Madonna lilies, polyantha roses and violas, edged with pinks and Munstead lavender. When building a pergola it is important to erect it according to the correct proportions. This one is 7ft. 6ins. high and 8ft. wide; a space of 12ft. is left between the pillars to allow sunshine and light to reach the lilies and roses.

The guinea photograph, sent in by MRS. CRESSWELL, *Copse Hill, Ewhurst, Surrey.*



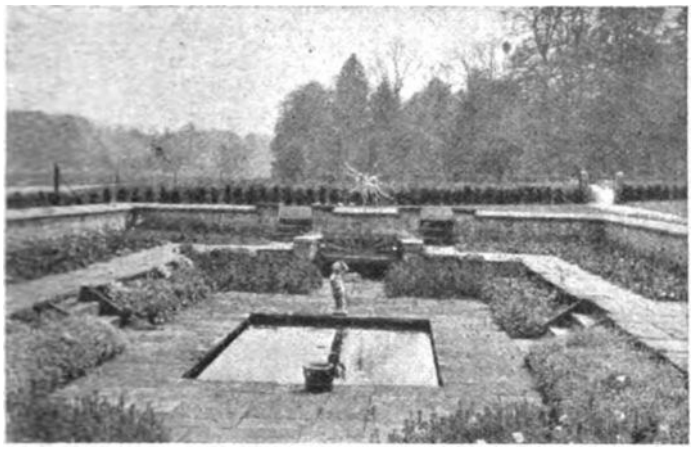
This photograph shows part of a large bed of Primula sikkimensis in a low, rather wet piece of ground at the end of my garden. The seed was sown in the autumn of 1924 and the seedlings pricked out in boxes the following spring. In the autumn of 1925 the young plants were moved into their permanent positions and this summer have been a wonderful sight. Many of the stems are 2½ft. to 3ft. high and are crowned with large heads of beautiful pale yellow sweet-scented flowers. This species is a splendid plant for a damp situation and well repays any trouble in cultivation. It is, moreover, a very hardy and good tempered garden plant. MISS AMY CAMERON, *Trinity, Duns, Berwickshire.* Award of 5s.



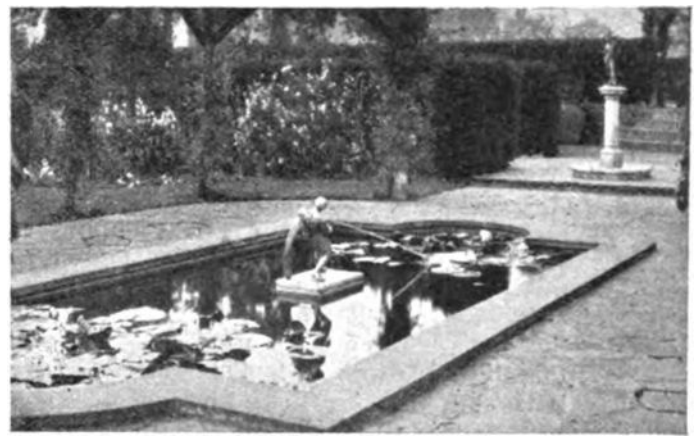
This illustration shows how crazy pavement can be made to look natural and beautiful in the same year as it is laid down. It is planted with such plants as alyssum, Tom Thumb antirrhinums, calendulas, and in alternate cracks with plants like cerastium, Arenaria balearica, Alyssum saxatile and armeria. J. HOPTON, *Ullerthorne Road, Streatham Park, S.W.16.* Award of 5s.

This illustration is of a portion of our rock garden about nine months after planting. The bank in particular faces east. The plants growing here are Campanula Bellardii, Primula capitata Mooreana in the centre beds, and Nepeta Mussini in the background. MR. R. BEVAN, *Crowsley Grange, Henley-on-Thames.* Award of 5s.

Digitized by Google



In view of the recent article in THE GARDEN *on the subject, this illustration of my sunk garden may be of interest. It is now five years old and was made and designed at home. The stone is grey limestone. Plants which are grown in the garden are as follows: Roses with an edging of Violas Maggie Mott and Imperial Blue on the top terrace, with forget-me-nots, polyanthus and other spring-flowering subjects followed on by antirrhinums, larkspur and Salvia patens and Blue Beard.*
LADY BROOKE, *Brookeborough, Ulster.* Award of 5s.



This illustration shows how attractive a formal pool can be made if laid out according to a simple design. It is placed in the centre of the garden with a pavement surround and an enclosing pergola, upon which rambler roses are trained. The small figure in the centre of the pool and the water lilies greatly enhance its beauty, while the figure on the pedestal on the pavement gives a finish to this formal arrangement. It is a simple design which greatly adds to the charm of the garden.
MR. H. R. BEETON, *Checkendon, Berks.* Award of 5s.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints (which should not exceed 150 words in length) is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Training Loganberries.

Readers who grow loganberries in large quantities may be interested to know how market gardeners treat this fruit. Each plant is set between *two* posts: one post takes the fruiting canes, while the young new season's canes are tied to the other post as growth advances. When the fruit is gathered, the old wood is cut out in the usual way, leaving one post bare, the other being occupied by the new season's growths, which are thus already in position for next year's fruiting. The advantages of this system are manifold, three of the most important things being tidiness, free access for the sun's rays to ripen the new wood, and avoidance of that tangle which results when new and fruiting canes are allowed to grow up together. It is a plan which should also answer with rambler roses grown on posts, for these, of course, flower on the year-old wood, the flowering canes being removed as soon as the blossoms have faded.—B. D. S.

How to Succeed with Dianthus neglectus.

Of all the rock pinks Dianthus neglectus, with its warm pink front and buff back, is one of the most beautiful. One of the most satisfactory also, for it is free from the habit of dying! Its even more beautiful relation, Dianthus alpinus, makes a practice of withering away for no apparent cause when it seems to be thoroughly established. Ten years ago I planted Dianthus neglectus in moraine mixture. The plant remained much the same size and produced each year about seven blossoms. Last September I transplanted it into a mixture of ordinary garden soil, leaf-mould from an old shrubbery, and a little sand, to which I added a dessertspoonful of burnt rubbish. The plant is now fully double the size it was in September and has produced eighty-one perfect flowers! They all opened at practically the same time, so that the foliage was completely hidden by a solid pink covering. I have had nothing more beautiful in my rock garden, and intend this autumn to try the same treatment for Dianthus alpinus.—G. H.

Charlock on Lawns.

During the latter half of April and early May I sowed down two new lawns. The ground was, a year ago, part of a cultivated field. The weather has been ideal for the young grass; however, a common field weed, charlock, made its appearance, so as to form practically a mat over the whole surface. Hand-weeding appeared a hopeless task; but the following has proved an efficient remedy in destroying the charlock without undue harm to the young grass: Dissolve 6 oz. of copper sulphate in a gallon of water, using hot water at first to assist in dissolving the green crystals. Avoid metal pails, using only wooden or earthenware vessels. Spray the solution when cold over the affected area, using a fine misty spray, and during a dry and sunny period for preference. In the course of a day or two the charlock begins to shrivel and die. If possible, spray the charlock when young, using approximately 1 gallon of spray to 50 sq. yds. of lawn.—J. W. H.

The Watering of Plants.

Where there is a large number of plants in 60's, and there is no need to use a watering rose, it will be found that one is apt to overwater, because of the difficulty in regulating the stream of water from the spout. A length of unjointed bamboo should be cut, and fitted into the spout of the can, and it will be found to minimise the danger of over-watering, and to allow for easier reach to the back of the staging.—J. R.

A Remedy for Woolly Aphis.

The following simple way of dealing with woolly aphis on an apple tree has proved to be very effective. In the lid of a canister punch a number of holes and then pour a small amount of paraffin into the tin. The canister is then suspended from the main stem of the tree affected so that, as the fumes arise, they are carried through the branches. The odour of paraffin seems to be extraordinarily distasteful to woolly aphis, and the insects soon disappear completely. This plan has often cleared a tree of the pest when applications of insecticides have been only partly successful. Now and again the paraffin in the canister should be replenished, although not a large amount will be required.—S. L. B.

How to Make an Indoor Rock Garden

I have a small unheated greenhouse, about 8ft. square, which I have made look very attractive all the year round. Instead of rows of pot plants, I have arranged the shelf where they used to stand as a rock garden, similar to those exhibited at flower shows. In the centre I have placed a shallow tin painted green and filled with water, and a little figure reclining on a piece of stone. Between the soil and the glass I have one row of plants; the soil of the rock garden reaches the top of the plant pots, in which grow ferns and graceful flowers, some of which droop and some which climb, such as ivy-leaved geraniums, etc., all making a pretty background, and the front has trailing plants like sedums, mosses, etc.—W. W. J.

Increasing Cordylines (Dracænas).

These popular and beautiful foliage plants may be easily increased by means of root-cuttings. Turn the old plant out of its pot remove several pieces of the thick tap-root (or underground stem) about an inch or two long. Insert these in a pan of sandy soil. Place in a propagating case. In a short time they will grow and develop into fine little plants. If the pieces are removed carefully, no harm will result to the old plant.—J. E.

A Second Crop of Tomatoes.

Where early tomatoes are grown, a second crop may be secured by the following method. When four or five trusses of fruit are set and swelling, the plants are stopped and some of the foliage removed. A fresh shoot is selected from the base of the plant and trained up beside the parent stem. When the fruit of the first crop has been gathered, the old stem can be cut out, and if feeding is continued a second crop almost as good as the first will be available before the end of the season.—F. W.

THE FRUIT AND KITCHEN GARDEN

The Present Treatment of Cucumbers in Frames.

VERY fine crops of cucumbers are grown in frames placed on hot-beds and on ordinary good loam without the hot-bed. Of course, the moderate heat from a firm, well made hot-bed does stimulate both root-action and top growth, and that early in the season, so that the cultivator gets the benefit of the first fine summer weather. Plants that were planted out in May are now filling up the frame with healthy haulm and leaves, and it is just at this stage that inexperienced cultivators go wrong in their treatment. Overcrowding means the weakening of the plants and fewer cucumbers, often the loss of a plant through damping off at the collar—the soil level. The main stems should be loosely pegged down to the soil, then the leaves and ends will be kept from touching the glass, where they are liable to burning by day and to be chilled at night. Just before the ends of these main stems reach the sides of the frames the points should be pinched off, with the result that many side shoots will grow, and at every joint young cucumbers will form. But just beyond the show of fruit at the first joint, stop the shoot. Another shoot will grow and also bear fruit, and this also must be stopped. Every side shoot should be similarly treated, then the whole frame will be gradually filled with fruit-bearing shoots and the cucumbers will be in all stages of growth. Gather the fruits while they are young, as their timely removal lessens the strain on the plant and thus enables it to go on producing more. Always pinch off the shoots—do not cut them—then there will be less risk of losing any through damping. If any damping is found, or any canker of the main stems near the soil level, rub in some dust-dry lime. Maintain a moist atmosphere and keep all water intended for use in a vessel in the frame itself. On cold nights place bags or mats on the glass to help in conserving the heat. —GEO. GARNER.

The New Strawberry Bed.

EVERY lover of the strawberry who wishes to make a new bed this year should form it as soon as possible now. Freshly layered young plants require as long a time as possible to grow in and make plump crowns before the end of November. Such plants will bear remunerative crops of berries next year and be extra strong then for a second year's fruiting, too. The soil of the border must be very carefully prepared. A shallow rooting medium will not yield the best results. Trench the ground now if the soil has not already been so treated. Trench two spits deep and simply loosen the subsoil, leaving it all below. Keep the top soil on the surface; some of it is sure to get mixed with the lower soil and thus improve it. All manure applied should be kept near the surface, as the plants are mainly surface-rooting. Some well rotted manure may be used, also basic slag on the surface, after the planting, at the rate of 4 oz. per square yard. This should be lightly forked in, not buried deeply. Early-rooted layers in small pots should be planted out before they become pot-bound, then there will not be any check to growth and the crowns will become quite plump and mature before the end of November—a very important matter. Taking the variety Royal Sovereign as an example, nearly all the new sorts possess large leaves, and ample room must be allowed for each plant to develop in fully. The approximate distance apart for the rows should be 24ins., and from plant to plant in the rows 18ins. Do not bury the crowns when planting, but make the soil very firm around the roots. Top-dress at once with half-rotted littery manure, and water through a rosed watering-can. The plants, so treated, should be quite snug throughout the winter.—G. G.

Raspberries and Loganberries.

THESE are a wonderfully good crop, in general, this year. The branches were laden with flower trusses, and the fruits set and have matured splendidly. Too often, while fruits are ripening, the cultivator takes a keen interest in them, but neglects the bushes soon after, leaving it to chance as to when and how he will deal with them further. Now, in this country our summers are short enough for the well being of fruit trees, and so we must do our best to help them, to get the wood matured and also strengthened for future crops. In most plantations there are very strong, sappy shoots and very thin, weakly ones. Both kinds should be entirely cut out directly the fruits are gathered, if there is a good supply of medium-strength young canes. Of course, the old fruit-bearing canes must be cut out first of all, as they are, as a rule, branching near the top and exclude light and sunshine. When the old and surplus young wood has been cut out, clear away all foreign matter and burn it. The retained canes should be allowed to sway about in the wind; they will ripen better so. Having cleaned the ground, apply a thin surface mulch of littery manure, if such be available; or one of leaf-soil and loam, mixed—leaf-soil one-third, loam two-thirds. Furthermore, apply water freely in dry weather.—HANTS.

Tomato Diseases.

INTENSIVE cultivation of the tomato has led to increased incidence of diseases of various kinds, but the man who grows his plants in what we might call the rational manner has least trouble. Coddling and forcing are prime causes in the introduction of disease. They do not actually cause the disease, however, but, provided that the germs of the disease are present (and they nearly always are), they rapidly lead such parasites to assume virulent proportions. Do not keep too moist an atmosphere; allow a free play of air round plants and not merely above them in the height of summer and, when feeding, apply a "balanced" manure in preference to one designed for one purpose alone. Potash, let it be noted, seems to be a potent factor in keeping plants healthy. When leaf disease, like rust, spot and mosaic, appears, keep plants decidedly drier, pick off the infested leaves largely and spray with a fungicide. Should it be wilt, sleepy disease or a disease causing collapse, nothing can be done, but the infested plant should be removed and the spot heavily limed; also spray. Fruit diseases like black spot may disappear if the diseased fruits are removed at once. In bad cases remove and burn the plant also. In all cases of disease water the plants with sulphate of potash, 1 oz. per gallon. Remember, always, that the tomato is a hardy plant, and do not coddle.—H. H. A.

Lifting Potatoes.

EARLY varieties, in many parts of the country, have yielded light crops of, mainly, small tubers. But they were sound and clean, so that there is not any waste. Late varieties look remarkably well at the present time, with the exception of a few, in various parts, which are diseased. Judicious spraying, even now, would be beneficial in numerous instances. But all mid-season sorts should be lifted, very carefully examined for any diseased tubers, and stored in good condition, rather than leave the tubers in the soil after their growth has ceased. If possible, avoid lifting tubers in rainy weather, as exposure to rain would hasten decay. Exposure to air, in a cool, dry shed, for several days, would be beneficial. I strongly advise this course prior to storing, as a second examination of the tubers can be made comfortably, and odd, diseased ones, if there are any, picked out. I have found this plan, on a large scale, result in very satisfactory storing during the winter months. Potato rust is present, in some batches, again this year. It is sometimes mistaken for the potato disease. When the leaves are rusted the haulm practically stops growing; the tubers do, certainly. Liming has a very beneficial effect. For several years I closely watched a potato plot—cropped with potatoes year after year; the haulm was badly rusted every year. Then a new tenant had the plot under cultivation; he applied a good dressing of lime, and even on the portion occupied by late broccoli the potatoes have not shown a single rusted leaf. The lime should be applied in the autumn at the rate of, approximately, 1 bushel per square rod. Spread the lime evenly on the surface, leave it so until some few weeks after Christmas; then, when the soil is found to be dry enough, lightly fork it into the surface only. Later it will be mixed with the soil to a greater depth.—CHRISTCHURCH.

How to Keep Down Celery Fly.

ALL growers of celery should keep a sharp look-out for signs of that very troublesome pest the celery fly. In some seasons the grubs of this insect will attack the plants over three or four months, and it is essential to take energetic measures without delay. It is the habit of the grubs to mine beneath the surface of the celery leaves and cause the well known blistered appearance by eating away the green colouring tissue of the leaf. If the attack is very severe, practically the whole of the foliage in the case of young plants may turn brown and, finally, the specimens may die altogether. One of the best ways of dealing with the pest is to examine the plants at frequent intervals and crush the blistered parts between the thumb and finger; very badly attacked leaves may be removed altogether, and these should be burned. If this method is followed from the first signs of the pest and at the same time the plants are kept growing vigorously by the application of plenty of water, it is almost impossible for the celery fly to make much headway. Syringing or spraying with tobacco water or any of the advertised insecticides is also to be recommended. A preventive measure which checks the egg-laying activities of the perfect insect is to dust the foliage of the plants with a mixture of soot and lime on dewy mornings.—L. B.

When Lettuces Bolt.

A LETTUCE which "bolts" or runs up to the flowering head before it has formed a good centre is of no service at all. The causes of bolting in lettuces are several, and in order to prevent the trouble the grower should never neglect certain points. For one thing, it is most important that the seed should be good; if you save seed yourself, never select it from plants that have started to run up to flower very early in their growth. Generally speaking, it is very much better to buy lettuce seed from a reliable dealer whose business it is to offer non-bolting varieties. Soil poverty is a common cause of bolting in lettuces. You cannot grow good lettuces on poor soil. If the young lettuces are not making the growth that they should and do not show

Digitized by Google

signs of early hearting, you may be sure that the plants are suffering from lack of food. Up to the time the lettuces are half grown you may much improve matters by applying guano or dried poultry manure and watering it in. Allow 1 oz. of guano to every square yard, or double the quantity of the poultry manure. When the lettuces are more than half grown they will not respond so well to the feeding. During the summer, cabbage lettuces frequently bolt as a protest against hot, dry conditions. You can get over this difficulty by planting on a north border under the partial shade of trees or in any semi-shaded position. Yet another cause of bolting is the presence of insect pests like aphides on the roots. These will often appear when the lettuces are quite small. If the young plants are badly attacked, it is a good plan to put in fresh specimens and destroy tthe others. Should you have no spare plants, lift the affected ones and then wash their roots in water. After this the specimens will often grow with renewed vigour, and it is curious that they are rarely attacked by aphides again.—L. B.

The Cabbage Gall Weevil.

ONE of the most destructive of cabbage pests is the gall weevil. The perfect insect is about in the summer, and it is a pretty little beetle of a coppery colour. The gall weevil lays its eggs at the base of the stem of the cabbage plant just at, or a little below, the ground level. When the eggs hatch the grubs bore their way through the skin of the stem and commence feeding on the soft interior. The irritation set up by the grubs causes the formation of gall-like structures, which often make the amateur think that his crop is afflicted with club-root. When cabbages are badly attacked by the gall weevil there is practically nothing to be done, as no insecticide or wash will reach the grubs in the stems. One of the best ways of keeping this pest under is frequent hoeing among the young plants. The soil knocking against the stems brushes away the eggs, and if these hatch on the ground the grubs die. Where there seems any chance of an attack by the gall weevil it is well to scatter sand which has been soaked in paraffin on the seed bed. After cabbages which have shown signs of gall weevil have been removed, dress the ground in the autumn with gas lime at the rate of 1 peck to the square rod (30¼ square yards) or quicklime at the rate of 1 bushel to the rod. Allow either to remain on the surface a few weeks before digging in. Avoid planting a similar crop on the same ground the following season, and in this connection it should be noted that the gall weevil will attack turnips and, indeed, almost any member of the brassica tribe.—S.

THE AMATEUR'S GREENHOUSE

August in the Greenhouse.

IF the greenhouse is overrun with climbers, there is sometimes a risk of the interior being too much shaded. Growth makes vigorous strides in July, if the weather is warm, a thinning out of the shoots may be necessary. Ferns, fuchsias, palms, begonias, etc., may do well with a certain amount of shade, but even these lovers of subdued light may suffer if the roof of the greenhouse is covered with a mass of climbers.

The cultural work among the greenhouse plants will include sowing, propagating and potting. Mignonette may now be sown in pots for winter flowering. Four-inch pots, containing about a half inch of drainage material, with a little dry, rotted manure and fine sand, will do nicely. The best way to obtain good plants is not to give them too many shifts from the seedling to the flowering stage. Seedlings often do very well when transplanted at once into their flowering pots.

Celosia plants raised from seed may now be potted. They bloom late in the season. Repot late sown cinerarias to replace the earlier batch. Transfer the primulas to 6in. pots in which they will flower.

Pelargoniums of the exhibition type that have done flowering may now be turned out of doors, allowing them a full exposure to sun and air. Give them no more water than will keep the foliage from falling off too quickly. After ripening for a few weeks these pelargoniums will be in fine condition to cut down.

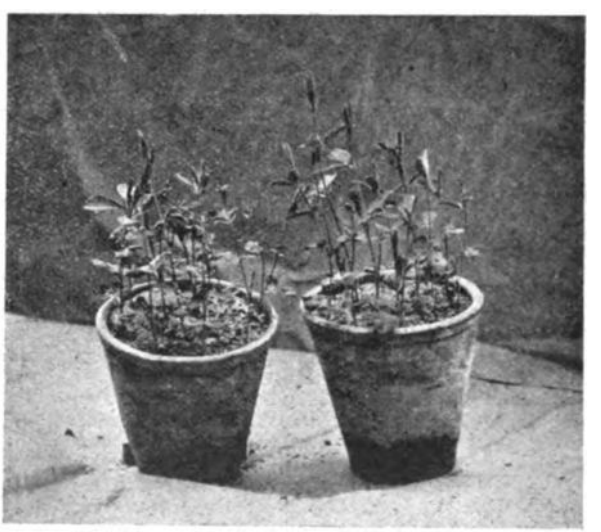
Cyclamen also require some extra attention at this season. Shift young stock into their flowering pots. A nice size of pot is the 6in. one. These subjects do best with a little shading from the strong sun and in a moderately moist atmosphere.

In August some fuchsia cuttings should be inserted in suitable pots for growing on through the winter. A light, sandy soil is preferable for propagating purposes; but ordinary garden soil, or loam, with a good admixture of a sharp sand will do very well. A sharp sand helps materially to make the cuttings take root. The practice of removing a few of the leaves when inserting cuttings is a doubtful one. The idea may be to reduce the facilities for evaporation, as the larger the amount of foliage, the greater the amount of moisture passed into the atmosphere. But plants receive part of their nourishment from the air, which in a sense they breathe, while the action of the sunlight on the green colouring matter of the foliage is highly beneficial. Therefore, it seems a mistake to remove some of the leaves from the cuttings.

The atmosphere of the greenhouse should be kept slightly moist by means of damping the house at least once a day during warm weather. Admit plenty of air, too.—J. W.

Painting the Greenhouse.

THERE is no better time than the present for painting and overhauling many greenhouses, particularly those which house pot plants, easily moved as required. These may quite well be placed in the open for a day or two in a good number of instances; at least, they may stand on the paths outside during the day and in the frame at night, if necessary. To do the work thoroughly entails a few day's initial preparation; first of all clean away all rubbish and wash down any dirty woodwork or glass with hot soapy water. At this stage, too, renew any glass or woodwork calling for attention, giving new wood a good coat of lead paint when in position. Broken and loose putty may be removed and new putty placed there, the paint brush being first drawn down the woodwork. Scrape off blisters, and coat exposed or bare wood with paint. If possible, limewash any wall and rub splashes of lime from the woodwork. After all these preparations, paint inside and outside carefully, remembering that best quality paint and slow, thorough work are amply repaid. On no account use creosote or wood preservative, and let the paint dry completely before it is wetted in any way.—LANARKSHIRE.



SWEET PEA CUTTINGS IN POTS IN A GREENHOUSE.
These can be taken now or from seedlings in the spring.

Sweet Peas from Cuttings.

IT is interesting to raise a few sweet peas from cuttings to provide flowers in the autumn. The plan is a very simple one to carry out, and the plants produced will continue in bloom until the coming of sharp frosts. The cuttings should consist of the top of plants and each should carry two or three well developed leaves, in addition, of course, to the growing tip. Each cutting should be 4ins. or 5ins. long and, after the removal of the lowest leaf, a cut is made squarely across the stem just below the joint. The removal of these shoots will not harmfully affect the parent plants, but will rather stimulate them to send out more shoots. Insert the cuttings in a fairly deep, well drained pot or box of very sandy soil, over the surface of which a good layer of sand is spread. Water well and then keep the box in a close frame, and in about a fortnight rooting will have taken place. Sweet pea cuttings will also root in the open border if the position is well drained and somewhat shaded. Of course, protection with bell glasses or hand-lights is essential if rooting is to take place. As soon as the little plants have rooted they may be removed to their permanent quarters. Watering, if the weather is dry, and applications of liquid fertilisers, will help the plants to grow quickly, and soon they will be in flower.

How to Raise Sturdy Schizanthus.

THE schizanthus is a very useful and accommodating plant, moreover, it is a beautiful one when well grown. At one time the old Schizanthus pinnatus was badly grown and the plants with their flowers almost resembled discarded weeds. To-day we have very fine strains and the knowledge and the will to grow first-rate specimens. When the seeds are sown in August the the resultant plants, if properly treated, have a chance to get well hardened and to grow sturdily before the winter season. To grow fine schizanthus plants we require two-

Digitized by Google

separate lots of composts; the first for the benefit of the seedlings, the second for the plants during their flowering period. The first, or seed compost, should consist of sweet loam, two thirds; sweet leaf-soil, one third. Use very small pots with a single crock in each one, place them close together on the stage or in a shallow box, fill them nearly to the brim with the compost level and water the soil. One hour later sow several seeds in each pot and cover with fine soil. In due course thin out the resultant seedlings to one in each pot. This course is better than that of sowing in pans or boxes and transplanting, as the young plants are never checked and can be re-potted without any serious check. From the first re-potting the soil should be well firmed in the pots. Grow the young plants as hardily as possible throughout the autumn and early winter, and, when frosts come, do not maintain a higher temperature than will just keep out frost. Before the winter get the plants well rooted, then they will grow rapidly in spring after the final potting. The compost for this potting should be richer than that for the young plants; some well-rotted manure, also bonemeal, will be beneficial. Sunny, dry shelves and ample ventilation on suitable days throughout the winter are essentials to success, coupled with great care in the matter of watering.—G. G.

SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Diseased Gooseberry Bushes.

Could you inform me what the disease is on these gooseberry bushes, and what remedies I can use to cure them?—W. V., Loughton.

The gooseberries sent for our examination are attacked by two distinct diseases. The greyish white, felt-like coating on the berries and the mealy powder on the leaves are caused by the American gooseberry mildew, the most serious trouble to which gooseberries are liable. The coral-coloured eruptions on the berries are caused by the cluster cup disease, and this is not nearly so deadly or disastrous in effect. The remedy for the latter trouble is to pick off and burn all berries or leaves on which the coral coloured clusters are noticed. This disease passes a part of its life cycle on sedges in the neighbourhood, and so long as sedges remain near there is always the likelihood of a similar attack in future years. It is seldom, however, that serious harm is done by it. With the gooseberry mildew, however, it is a much more serious matter. Probably the disease is deep-seated, and affected wood must be pruned out, in due season, if the bushes are to be freed. Spray all the bushes with the "A.P.S." wash (a preparation sold by Messrs. Murphy and Son, Limited, The Cedars Laboratory, Mortlake, S.W.14) as soon as possible. Diseased berries, unfit for use, should be gathered and burned, and on no account left to fall on the ground. In late August the bushes should be "tipped," meaning that the top 2ins. or 3ins. is cut off each shoot on every bush, the "tippings" being burned immediately and not allowed to fall to the ground. Prune the bushes hard at the winter pruning time, and in late February give the ground about and beneath the bushes a good dressing of quicklime. You should have at hand a supply of lime sulphur with which to spray the bushes just before they come into flower next spring, and it would be well also to spray a few weeks after flowering next season with the "A.P.S." wash. This treatment should rid the bushes of the disease; but if they have been so weakened and spoiled in growth by this present epidemic, perhaps the cheapest and best thing to do would be to uproot and burn them, for the disease is very contagious, and on old bushes persistent.

The Use of Nitrate of Ammonia.

I took over an allotment on March 25th this year which had been under wheat and sown with clover last year. I have, so far, dug and planted a certain proportion of it, and need a little advice as to the use of ammonium nitrates of which I have had 28lb. given me, but do not know how to use same on plants. If you could give me some hints as to what plants it can safely be given, and quantity, I should be greatly obliged.—A. H. M., Manchester.

At the earthing-up stage of the potatoes you may use 2 oz. per yard run of row, applying the manure before drawing up the soil. To the peas and beans a similar quantity may be used while the plants are growing freely. During July scatter 1 oz. per yard run of row between the rows of onions and lettuce, but none must be given to the radishes. Treat the sweet peas in a similar way. For the chrysanthemums, raspberries and roses, use 2 oz. per square yard and water it in if the weather is dry at the time.

Propagating Laburnum.

Please tell me, will laburnum strike from a cutting, and what month?—R. F., Carmarthen.

It is possible to root cuttings of laburnum in July, but as they do not make such strong, healthy trees as those readily raised from seeds, this method of propagation is seldom practised. One or two hybrid laburnums which do not come true from seeds are grafted on seedling plants in early spring.

Manures for Various Subjects.

I have just made a garden at a new house, and wish to know what manures or treatment to give the soil, which will contain the following, in beds or borders. Rhododendrons and azaleas; chrysanthemums, stocks, asters, antirrhinums, gladioli), sweet peas, violas and calceolarias; roses. The soil is fairly light and was composed of turf, which has been well dug up about two months ago. Please state what should be done to a lawn which was laid with turf three weeks ago, and has been kept well watered and appears to be doing fairly well.—C. S., Bradford.

The best kind of manure to use for rhododendrons and azaleas is well rotted cow manure and an annual top-dressing of Thompson's Plant Manure. For chrysanthemums, powdery fowl manure, old lime rubble and bonemeal with potting soil, with Clay's manure added when the plants are growing freely in the summer. Rotted manure mixed with soil 1ft. below the surface is best for gladioli, manure water being applied when the flower spikes can be felt. For sweet peas, rotted manure, and a little dry fowl manure should be put in the trenches in autumn. Three ounces of superphosphate per yard run of row should be applied during the summer (about three times). For roses, good rotted manure in the soil, with applications of liquid manure in May and June. For the other plants, old lime rubble should be applied in the autumn and bonemeal and rotted manure in the spring. Regarding your lawn, the best treatment to give it now is to brush in sifted soil between the turves, roll and mow in due course. We trust that this information will be of service to you in preparing the soil for the shrubs and plants you mention.

THE BLACKPOOL FLOWER SHOW

BLACKPOOL'S first flower show, which was opened by Sir Walter de Frece, M.P., on July 20th, was, from a floral standpoint, a huge success, both in quality and quantity. The exhibitors gave of their best, with the result that nothing but praise was heard from everybody. The Corporation of Blackpool are to be congratulated on providing such a wonderful display on this their first attempt at a flower show on a really large scale. The arrangements were admirable in every way, and the success this year augurs well for future occasions. There is little doubt that the first show was an unparalleled success, to judge from the fact that more than 2,000 entries were received. Every class of flower was well represented, particularly roses and sweet peas and carnations. Messrs. Dobbies obtained a gold medal for the most distinctive rose in the show, with their Duchess of Atholl. This rose, a coppery orange, is a first-class variety for decorative and garden purposes, of grand upright habit and very hardy. It is also mildew proof. The Edinburgh firm also had a fine collection of sweet peas and dahlias. Their sweet peas Hero and Gleneagles looked very well. Among their dahlias two new varieties, Pitlochry and Dunrobin, both collarette varieties, were very choice. Messrs. McGredy were showing, among a large representative group of roses, Cherry and Patience, the former a new rose not yet in commerce. Messrs. Carters achieved distinction with their excellent exhibits of flowers and vegetables. In their admirable floral display, in the centre of which four fountains were playing, gloxinias, godetias, hydrangeas and sweet peas were present in profusion. The varieties were too numerous to mention, but we particularly noticed Godetia Pink Pearl and Gladioli Vesuvius and Alice Tiplady. For this display they received a special 100-guinea gold cup; while they were also awarded a large gold medal for their collection of vegetables, in which could be seen a choice of their well known varieties. They received another gold medal for their garden. Messrs. Bees staged a very large range of flowers, including roses, delphiniums, herbaceous and other hardy plants. The display was particularly fine indeed, particularly their herbaceous plants, which were all well grown and uncommonly good. Mr. Bolton exhibited his high-class sweet peas, and, considering the recent bad weather we have had, it was surprising how well they looked. Outstanding was his Sweet Pea Mrs. A. Searles, an excellent new variety. The carnations were at their best. Messrs. Allwood's Sussex Rosalind, and Edward Allwood were very pleasing, as was Messrs. Crowhurst's new Amy Weston. Messrs. Engelmann, whose carnations are too well known to need much writing about, had their usual excellent display. We think White Pearl and Janet were the pick of their group. Messrs. Woolman's Cockatoo was well worth seeing, as also was their Shirley Surprise. The lupins and delphiniums of Messrs. W. H. Simpson were particularly good, among them Lupin Rosalind and Delphinium looked well. We liked Messrs. Lomas' Iris Anglica Queen Mary, a new seedling.

The rock gardens were a delight to the eye, and the judges must have found considerable difficulty in awarding the prizes. Mr. Gavin Jones took the £50 trophy with a simple but impressive rock garden in red sandstone. He had used much larger rocks than are generally seen in a rock garden, which gave it an appearance of strength and, although not too well clothed, there was just enough to give it an air of simplicity.

WALLFLOWERS FOR EVERY GARDEN.

WALLFLOWERS are among the favourite flowers of the garden, and in spring there is no garden, however small, that can afford to be without a bed of these brilliantly coloured spring plants. They are most accommodating subjects They look well by themselves or they can be used in association with many other spring-flowering plants They combine well with daffodils and tulips or blend effectively with forget-me-nots or polyanthus primroses. They are not fastidious in their requirements. They thrive in any ordinary garden soil in a shady or in an open and sunny position During the next few weeks in common with other biennials, they should be planted out in their flowering positions If seed was sown in April this year, the seedlings must now be transplanted. If seedlings are not available, plants should now be purchased for stocking next year's spring garden.

THE GARDEN

VOL. XCI.—No. 2906. AUGUST 13, 1927. PRICE TWOPENCE.

CITIES OF GARDENS

QUITE a number of our larger cities have held Garden Competitions this summer. In Glasgow, Manchester, Birmingham and Sheffield various organisations have held, or are holding, popular garden contests, with a view to encourage the town dweller to take a greater interest in the art of gardening. In London the biggest single contest ever organised has just concluded.

All these competitions are good, in that they give publicity to the æsthetic and recreational value of gardening. An attempt is now being made by the Gardens Guild to link up these various efforts into a National Association, and truly, many of our big towns have need for such a movement. The Marquess of Northampton broadcasted from 2 L. O. his impressions of some of the London Gardens, recently, and he appealed for the support of all those who wish to encourage this work of the Gardens Guild.

In the new Association, which is to be called the National Town Gardens Guild, Mrs. Marion Cran is Honorary Treasurer, and Mr. R. Sudell the Honorary Secretary. The Association already has the support of many notable people. It is a movement that deserves the attention and whole hearted support of all organisations as well as individual amateurs who take an interest in gardening.

This Week's Work

For Gardens in the South and Midlands.

Take cuttings of summer bedding plants.

Cut out old fruiting canes of raspberries and tie in young canes.

Sow onions and spring cabbage.

Earth up celery and lift mid-season potatoes.

Finish summer pruning fruit trees.

Pot up Roman hyacinths, freesias and nerines.

Sow cyclamen seed in pans and germinate in a warm greenhouse.

Sow winter-flowering stocks in boxes placed in a cold frame.

Forthcoming Primula Conference.

THE Royal Horticultural Society is making plans for the resumption of the conferences upon important garden matters which, before the war, did so much to bring together those who had special knowledge and to spread it over a wide field. The first conference of this new series will be held at Chelsea in May next, and the subject will be "Primulas." Arrangements are being made to set aside a special tent at the Chelsea Show for the exhibition of a representative series of both species and varieties of this great genus which has, of late years, received so many valuable additions as the result of explorations in China, Tibet and Upper Burma, and to hold a conference between those interested in another tent in the Chelsea Hospital grounds on the second and third days of the Show. This early announcement is made in order that growers of primulas of all kinds may prepare for their exhibition at that time and to invite the offer of papers upon the cultivation, characteristics, variations, native habitats, etc., of primulas. The Director of the Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey, will be glad to hear from intending exhibitors and to receive offers of papers to be read at the conference.

The Amateur Fruit Show.

THE Royal Horticultural Society's Fruit Show, open to all amateurs and market growers, whether Fellows of the Society or not, is to be held in the Society's Hall, Vincent Square, London, S.W.1, on Tuesday, October 11th. There are 115 classes, divided into six divisions, of which Divisions I, III, IV and V are open to amateurs only, Division II to market growers and Division VI to societies affiliated to the R.H.S. It will be noticed in the schedule that in consequence of the fact that finer varieties of grapes are now grown, Class 4 only asks for two varieties. In the single dish classes for grapes, Lady Downe's has been substituted for Black Hamburgh, and Appley Towers takes the place of Prince of Wales. In place of the class for a collection of eighteen dishes of hardy fruits, a class for twelve dishes has been introduced. Peaches and figs are included. The section for market growers has been extended with a view to encouraging exhibits of choice fruit in non-returnable boxes. In the single dish classes for apples, a new class has been made for Duke of Devonshire. Altogether the schedule is much more attractive this year, and the Show merits the attention of all keen amateur fruit growers. Entries for the Show close on October 4th. Copies of the Schedule may be obtained on application to the Secretary, R.H.S., Vincent Square, London, S.W.1.

Daffodils at Wisley.

IN pursuance of their policy of giving awards to plants intended for garden decoration only after trial in their gardens, the Council of the Royal Horticultural Society is this year planting a standard collection of daffodils at Wisley representative of all the recognised sections and of known value in the garden. Growers of seedlings are invited to send six (or three) bulbs of their varieties for trial against this standard collection. These bulbs should reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, as soon as possible and not later than September 15th, 1927.

We are indebted to Messrs. Carters of Raynes Park, for the use of the illustration which appears on the cover of this issue. The wallflowers shown are a few varieties of this firm's fine strain of these attractive spring flowering plants.

This Week's Work

For Gardens in Scotland and the North.

Remove old large leaves from strawberry beds.

Plant Iris tingitana for Christmas bloom.

Bend over stems of onions to assist ripening.

Make a small sowing of parsley for winter use.

Thin out weak growths of dahlias.

Insert cuttings of geraniums, pansies and violas.

Plant Crocus speciosus for autumn display.

Begin autumn sowing of onions.

Pot up early batch of Roman hyacinths.

Complete the lifting of early potato crops.

Clear away all vegetable refuse and fork the soil.

Digitized By Google

CROCUSES FOR THE ROCKERY

NOW that the season of crocus species must be prepared for, it may not be out of place to sing the praises of some of these little gems for the rock garden. When I say for the rock garden, I mean that that is the most suitable place for outdoor culture. But, unfortunately, at the time of year when they flower, the chance of these delicate flowers doing themselves justice in the face of the elements and the depredations of slugs, is small, and I think that the shelter of a sunny, cold house undoubtedly allows them to give of their best. But how rarely does one meet these flowers, even in the collections of keen enthusiasts. When one mentions autumn crocuses, one is usually shown colchicums and great is the surprise evinced when the real flowers of crocuses are shown. Most of these species are easily obtained from reliable bulb dealers, although some of the daintiest are rather expensive. It is nearly possible to have continuation of bloom of a different species from the middle of September to the end of March. To begin with, Crocus speciosus bursts into bloom in the middle of September, with its lovely large blue-violet feathered petals. This is quite cheap, and, blooming early stands a good chance when grown out of doors. This is followed by C. pulchellus, a dainty lavender blue crown with white anthers. At the same time comes C. cancellatus, rather similar, but of a pale lilac colour, with bluish stripes. Before these last two have finished flowering comes C. corsicus, again very similar but of a more globular shape. Then the succession is kept up by C. speciosus albus, quite the gem of all, rising 4ins. to 5ins. high and opening out flat in the sunshine. C. nudiflorus is also in bloom at the same time, of a beautiful uniform deep lilac, with orange stamens. Then comes C. zonatus, of pale lavender with deep orange ring at the base of the petals. This is a very good doer, multiplying rapidly and throwing as many as eight blooms to a bulb. Also, we now have that very quaint bloom of C. iridiflorus, which really reminds one of an iris when the sun is out, as three petals lie out flat disclosing three short petals standing up straight in tubular form with a veritable tassel of orange stamens. I find that this crocus grows larger and flowers better when planted in a well drained bed of moist peat, such as a tourbière. Two other species which also enjoy this treatment are C. Salzmannii, of a shaded lilac colour, and C. Clusii, rather similar, but later flowering; both of these have long pointed petals. The species enumerated have taken us into early November, and now comes C. ochroleucus, small and white with an orange base; this is also a good doer.

CROCUS TOMASINIANUS, ONE OF THE CHOICEST OF THE MANY SPECIES.

After these I prefer to grow the following in 6in. pots in a sunny, cold greenhouse, where the wind, rain and slugs are more easily kept at bay. Towards the end of November comes C. Korolkowi, a dainty bloom only a few inches high and of a beautiful purple colour with the usual orange stamens. In the cold house these flowers will take one well into December, when about Christmas time the little orange blooms, with an expanded base, of C. vitellinus, will take their place. These are followed, soon after Christmas, both in the cold house and in the rock garden by C. Imperati. This species has only to be seen for its beauty to be realised; and when once seen I cannot imagine any flower-lover not growing it. It is cheap and multiplies very rapidly, and a large colony of its expanded blooms on a sunny day in January or February gladdens the heart and breathes

THE BEAUTIFUL CROCUS SPECIOSUS ALBUS, AN EARLY FLOWERING VARIETY.

CROCUS IMPERATI, A SPECIES FOR EVERY GARDEN. IT GROWS RAPIDLY AND IS INEXPENSIVE.

Digitized by Google

of the approach of spring. The unopened flower is of a brownish buff, with deep purple featherings, and when it opens in the sun the interior is lilac with orange stamens. The succession of blooms often lasts six weeks, until the middle or end of February, when its place is taken by the spring-blooming species. The first of these is C. ærius major, a lovely blue-violet and its variety, C. ærius major Celeste, of a paler shade. C. etruscus with deep lilac inner petals and paler outer ones is also very pretty. Next comes C. Sieberi, one of the bluest of all, with quaint globular shaped cups with yellow bases; this is also a good doer. Then there are two dwarfs, quite the smallest of all, one C. Aucheri, is deep orange and scarcely grows an inch high, while throwing many blooms to each bulb, and C. Olivieri, very little larger and of a pale lilac with purple featherings, very similar to the Scottish crocus, C. versicolor, which is, however, one of the last to bloom, often being at its best about Eastertime. Very similar to C. Olivieri and flowering at the same time, but slightly larger is C. lævigatus. Also, at this time, is C. Fleischeri, rather small for its height, but of a pure white with very deep orange stamens. Next comes the pure butter yellow C. aureus and its paler lemon yellow variety, C. aureus concolor; the first of these is very like a neat dwarf form of the common yellow crocus of gardens, which is also now in bloom. Following these in early March comes the last of the species to bloom. This is C. Tomasinianus, one of the very best, as it is as cheap as many of the ordinary crocuses grown so widely, and it is also an excellent grower and flowerer, with pointed petals of delicate lilac, a group of which will produce flowers of many shades. This species seeds itself freely and comes up in quite unexpected places, a good colony soon being formed.

These short notes are by no means complete, but if they should encourage keen gardeners to try some of the species described they will have served their purpose, and one will not so often be shown colchicums, usually faded and slug-eaten, and be told that those are the only autumn crocuses known. H. STEWART WACHER.

CYCLAMEN FOR GREENHOUSE DECORATION

CYCLAMENS in many beautiful varieties are more or less indispensable, not only for furnishing the stages in the greenhouse and conservatory, but also for house and table decoration. The cut flowers last for a long time in a fresh condition. Cyclamens belong to the Natural Order Primulaceæ; there seems to be some doubt as to the actual date of their introduction and cultivation. The many varieties cultivated at the present day have been obtained by seed selection.

Cyclamens are easily raised from seed, but it is very important that the latter be fresh. Old seed is often slow and uncertain in germination. It is the general practice to sow seed during August, the resulting plants flowering about fifteen months later. On the other hand, it is possible, with good cultivation, to flower the plants in twelve months from seed sowing. From seed sown at the end of December or the beginning of January I have frequently produced good flowering plants within twelve months. However, it should be remembered that such results are only possible out in the country where there is plenty of light during the winter. In the immediate neighbourhood of London and other large towns I would advise sowing about the middle of July. However, for general purposes it is best to sow seed about the middle of August. The compost for sowing should be light and open, consisting of a good medium loam, with the addition of some leaf-soil and enough silver sand or old mortar rubble to keep the whole open and porous. I advise the use of old mortar rubble in preference to sand at all stages of the plant's cultivation, as I consider that lime in some form is essential.

The compost in the seed-pans or boxes should be made fairly firm and the seeds sown singly about 1in. apart and ½in. deep. As germination is usually irregular, this method allows of the more forward plants being taken out without unduly disturbing the others. The seed-pans should be well watered, covered with pieces of glass and kept shaded until germination takes place. The seeds may be germinated in an ordinary greenhouse, but it is an advantage if they can be placed in slight bottom heat, or at least in a warm moist house where a temperature of about 60° Fahr. can be maintained. After the seeds have germinated, the seed-pans should be placed on a shelf well up to the roof glass.

About the beginning of November the bulk of the young seedlings should be ready for pricking off into pots, pans or boxes, according to the quantities required. At this stage some cultivators place the seedlings directly into thumb pots, but on the whole they are best pricked off into pans or boxes until January, when they may be potted off singly into pots. During the winter months they are best grown in a warm moist house where a temperature of 55° to 60° Fahr. can be kept up. As they increase in size and the season advances, they should be accustomed to cooler conditions, and during the summer months they are best grown in low pits or cold frames, where they can be kept well up to the roof glass. It is also an advantage if the frame lights can be pulled off, as towards the end of summer the plants benefit greatly by dews at night.

FOR PURITY OF COLOUR AND GRACE OF OUTLINE FEW GREENHOUSE PLANTS CAN EQUAL THE CYCLAMEN.
Their flowers always last a long time in bloom.

Towards the end of April or beginning of May the young plants should be ready for a shift into 3in. pots. For this and subsequent pottings a larger proportion of loam should be used, with the addition of a 6in. potful of bone-meal to every bushel of soil, or, where it can be obtained, some dried cow or sheep manure—rubbed through a fine sieve—may be used with advantage. The pots should always be clean and well drained. Pot the plants fairly firm, keeping the young corms just on the surface of the soil. From the end of June to the middle of July the most forward plants should be ready for placing in their flowering pots (48's).

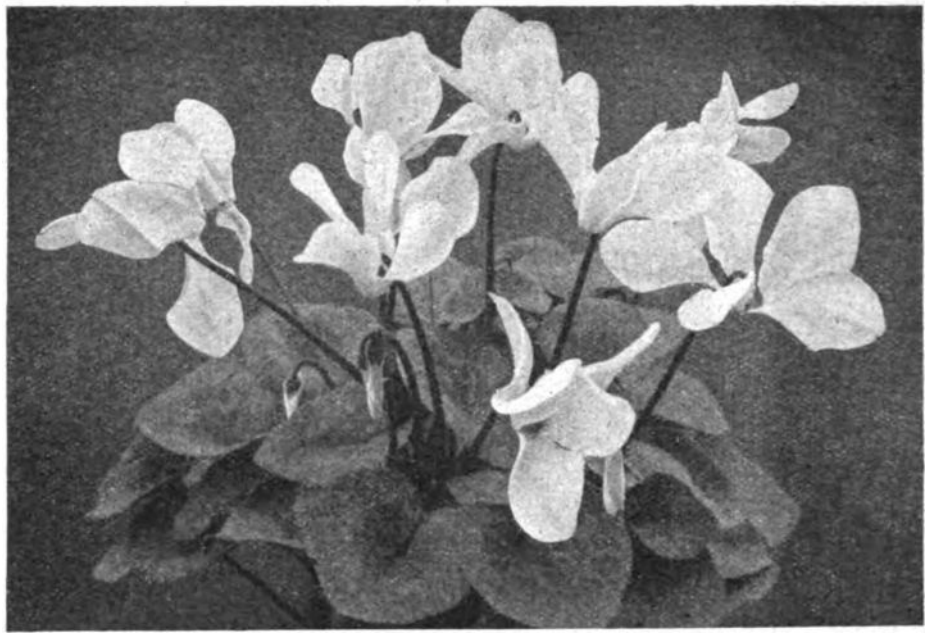
Careful watering and the maintenance of cool, moist atmospheric conditions are the essentials of success with cyclamens. Admit plenty of air on all favourable occasions; draughts, of course, should be guarded against. The bed on which the plants stand should be kept moist and the plants sprayed over during the morning. They should also be sprayed again during the afternoon, when the frames should be closed for an hour or so, afterwards giving a little air during the night, or the lights may be removed altogether so that the plants get the benefit of the dew. The plants should, of course, be kept shaded during bright sunshine. When grown in frames it is an advantage if cyclamens are stood on inverted pots, thus allowing the air to circulate freely among them.

Towards the end of September plants in cold frames should be removed to span-roofed pits or a cool, airy greenhouse, keeping them well up to the glass. When they have well filled their flowering pots with roots, they may be fed with diluted liquid cow manure and soot water. Sheep manure is also excellent for the same purpose.

If desired, some plants for early flowering may be brought on in a slightly warmer temperature, remembering, however, that the best results are obtained by cool treatment. Cyclamens can be grown on for several

Digitized by Google

years, but at the present day it is usual to raise them from seed each year. If it is decided to grow some of the plants on, they should, after flowering, be stood in cold frames, watering them in the usual way. As the old foliage gradually dies off, the plants should be kept on the dry side for several weeks, and when they show signs of starting into fresh growth they should be turned out of their pots and all the soil shaken off the roots. Afterwards place them in as small pots as possible. After potting, stand the plants in a cold frame and water very carefully until some new roots are formed. When they have well filled their pots with roots they will require a shift into larger sized pots, the cultural detail being the same as that advised for the young plants.



GIANT WHITE, ONE OF THE FINEST OF MODERN CYCLAMEN VARIETIES.

Instead of potting on the old corms, some growers plant them out in a bed of rich soil in cold frames, or even outdoors, lifting them and placing them in pots during September.

With their beautiful marbled foliage and elegantly poised flowers, cyclamens are ideal for decorative work, plants in cool rooms keeping in good condition for many weeks. Cut flowers are also excellent for decorating dinner-tables and for filling small vases. The flowers should be pulled out, not cut, as the decaying end is apt to affect the young buds, which are thickly clustered on the top of the corm. The hard end of the flower stem should be cut off and the cut flowers placed at once in water, for if allowed to flag it is difficult to get them up again, especially so with the giant varieties. If flowers are sent for any distance, they should always be placed in water for several hours before packing. If some moist material is wrapped round the ends of the stems and the flowers packed tightly in tissue paper, I have always found them travel well. When unpacked the stems should be slit upwards for several inches and the flowers placed in water as soon as possible. The smaller-flowered varieties, I may say, generally carry best.

If cyclamens are kept too warm and in a dry atmosphere, aphis and thrips may prove troublesome. Fumigation will, however, prevent and hold them in check; but if correct cultural methods are followed, these pests should not cause any trouble. Begonia mite, or so-called rust, is, however, much more serious, and, although it may not appear during the summer when the plants are in cold frames, it often proves troublesome during the autumn and winter, when the plants are growing in a warmer and drier atmosphere. This pest damages both the foliage and flower-buds, causing the latter to become deformed and marked with brown streaks. The best preventive and cure for this pest is the occasional use of Campbell's Sulphur Vaporiser. Where houses are infested with vine weevils their larvæ often prove very destructive, harbouring right under the cyclamen corms and feeding on the roots. All plants which suddenly flag without any apparent reason should be examined, and if larvæ are found, they should, of course, be destroyed. Again, every opportunity should be taken to destroy as many weevils as possible. At night, plants should be shaken over a white sheet or tarred trays; houses should also be kept clear of all rubbish, and broken walls repaired.

There are now many beautiful varieties of cyclamen which come true from seed.

The colours range from pure white, as seen in Giant White and White Butterfly, through varying shades of pink to cherry red and crimson, also rose and salmon. Among named varieties Firefly, Vulcan, Pink Pearl and fringed Pink Pearl may be mentioned, also the crested variety Eileen Low. There are now varieties with salmon and salmon-scarlet flowers, like Bath Beauty and Salmon King; while the silver-leaved salmon is worth growing for its foliage alone. In this respect a large batch of cyclamen provides a wide range of beautiful leaf markings, which adds considerably to their decorative value. In addition to the crested varieties, which have a raised crest on the centre of each petal, there are now a great variety with frilled or fringed petals. These are generally known as Papilio varieties. Although they find many admirers, they lack the form and charm of the smooth-petalled varieties. They are all, of course, extremely interesting as showing the wide range of colour and form that has been evolved.

HINTS FOR DAFFODIL GROWERS

FOR some of us springtime is daffodil-time; to others daffodil-time no more than the herald of springtime; but whether we aim at a succession of blossoms from January until April, or whether our object is no more than a few pleasing garden groups here and there in their natural season, no time should now be lost in making up our minds upon the matter and getting the work attended to. September or October will be quite soon enough for planting daffodils out of doors, but August is quite late enough for the "Poets" and Barri groups. A safe rule is to plant the "red-cups" as soon as possible; as a matter of fact, they never stop growing in their natural state, and the longer they are out of the ground the less satisfactory will be the results next year.

When purchasing narcissi or daffodils it is not safe to be guided by price alone. The small sizes are known as "rounds" or single-nose bulbs, and it will be seen from the illustration that in any given variety there will be several sizes of these, all perfectly healthy and capable of producing one single flower, larger or smaller according to the size of the bulb. Older bulbs are known as double or triple-nose, and will, of course, produce flowers from each "nose." When purchasing varieties of flowers and vegetables which are raised from seed it is possible to buy at greatly varying values. With bulbs this is not always the case. A small size single-nose bulb has a market value of about half that of a large one, and a double-nose bulb is worth half as much again as a "single-nose." Thus it will be seen that "double-nose" bulbs costing 2s. a dozen and producing *two flowers* are better value than "single-nose" bulbs at any price over 1s., while puny bulbs of the same variety will be dear at half this price. If,

Digitized by Google

therefore, you pay top price, specify your requirements on your order as "double-nosed or over," but do not expect to receive such bulbs when you search a score of catalogues in order to choose the lowest price. One often hears the expostulation that "so and so" supplies at "half the price"; quite so, and so would his competitor if you specified "seconds" or "thirds" or "same size as supplied by so and so." Another point to bear in mind before leaving this subject is that "top size" is a much-abused term. *Verb. sap.*

Select Healthy Bulbs.

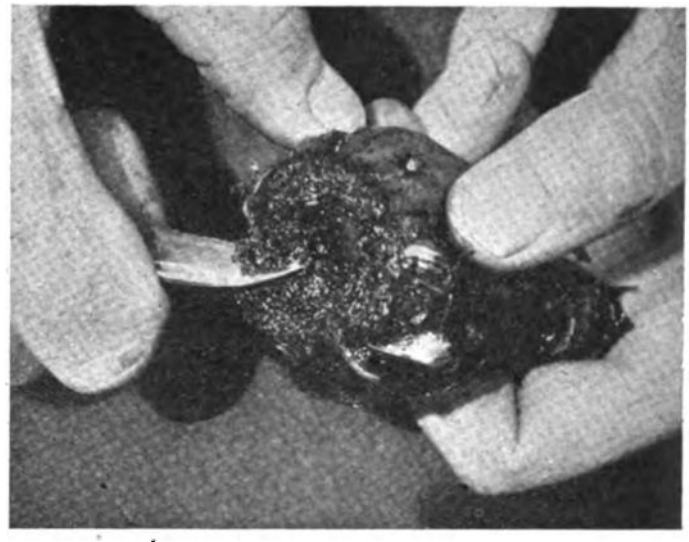
Now in choosing your narcissus bulb, first judge if it appears to be sound, hard, heavy and well ripened. Then press your thumb firmly in at the neck. If it is noticeably "hollow" to the touch, carefully scrape the base in search of a tiny brown-edged aperture. This is the sign of the merodon or narcissus fly, the larva or maggot of which is placidly browsing within the bulb. The next thing to look for is eelworm. This devastating pest can usually be detected by *carefully* slicing off the *extreme* tip of the bulb (see illustration). If this operation is conducted before September, not the slightest harm will result, as new growth has not yet advanced to this point. If the bulb is healthy, its flesh will be clean and white. If it has been attacked by eelworm, there will be brown concentric marks, which are in fact the tips of tainted bulb scales. Exploration at the *base* of the bulb will reveal further evidence of trouble in the form of rotting scales if eelworm is present.

A HEALTHY NARCISSUS BULB ATTACKED BY THE MERODON FLY. *Note the small hole in the base.*

A third and final scrutiny should be given to the base. If it is firm, hard and clear, it passes inspection. If corky, explore with a curious fingernail or the point of a knife. This "corkiness" is the sign of *basal rot*, and should it be more than skin deep, again reject. The variety Horsfieldii is exceptionally liable to this disease, while Victoria—a flower of similar colour, proportions and price—is seldom attacked. Under no circumstances should such tainted bulbs be planted, for they will permanently infect the ground. Unhappily, millions of infected narcissi and daffodil bulbs are sold annually to "bargain hunters."

The Depth to Plant.

Narcissus and daffodil bulbs appreciate deep planting. For permanent positions from 8ins. to 10ins. below the surface is not too much, and deeply planted bulbs are much less liable to attack by merodon. Within my experience bulbs planted at this depth are seldom, if ever, attacked, and there is the further advantage that the ground above them may be dug and used for planting annuals. The soil should be worked for a foot below the bulbs, and if not naturally of good quality should be enriched with *well decayed* manure, leaf-mould or peat moss, which latter substance is excellent for supplying humus to sandy or barren soils or lightening heavy ones. A sprinkle of steamed bone flour and sulphate of potash will supply all necessary stimulant if very old manure (such as an exhausted hot-bed) is not available. It is not generally known that if the same variety is planted in a bright and sunny position and in deep shade, both plantings will do equally well, and the flowering period will be extended for from two to three weeks.



AN UNHEALTHY BULB INFECTED WITH BASAL ROT.

Varieties worth Growing.

Now as to varieties. For indoor work for bowls, Grand Monarque, Grand Primo or (yellow) Soliel d'Or. Peat moss, light soil (to which a little charcoal has been added) or even pure sand will do equally as well as "prepared fibre." *These varieties do not do well out of doors.* There is no need for if early planting is up your bulbs, cover the "dark cellar" practised. Just plant them with the potting material and keep them in the open in a moist, shady place. For early flowers choose Golden Spur (bright yellow). Plant them 1in. apart in deep boxes or pots in *August*, and keep them in the open and just moist. Bring them indoors in early December and you will have flowers at the end of January. The same variety planted outside will flower in early March. King Alfred forces well, but it is rather expensive. Princeps is a bicolor trumpet which flowers with N. ornatus Golden Spur, or ornatus maximus—not recurvus—must be chosen if early "poets" are required. By the time two batches of early flowers have been brought through, the first outdoor blooms will be showing. Selection is only limited to one's ability to finance our hobby. Among the best varieties *at moderate prices* I should make the following selection:

Golden Yellow Trumpet Daffodils.—King Alfred (where it will flourish), Tresserve, Olympia, Golden Spur and Obvallaris.

Bicolor.—Emperor, Empress, Sir Watkin, Victoria, Horsfieldii and Princeps.

White or Whitish Trumpet Flowers.—Mme. de Graaff, Southern Gem and Mrs. W. O. Wolseley.

Narcissi with Small Cream or Yellowish Centres.—White Lady, Silver Penny, Leonie and Homespun.

Narcissi with Red or Orange Centres.—Marshlight (about 6d. each), Lucifer, Sunrise, Will Scarlet, Bedouin, Red Beacon, and Barrii Conspicuus.

Narcissi with Red-rimmed Centres.—Lady Moor, Horace, Poeticus ornatus and recurvus. This last mentioned is the late flowering but better variety. If you wish to grow the double sweet-scented poeticus variety, you *must* plant it deeply in moist soil or you will get nothing but leaves.

The selection of new kinds to be found in seedsmen's catalogues is endless, but it is the safest plan to choose all new and unknown varieties *when they are in flower*.

H. L.
